Lecture 1: What is Calculus?

Calculus is a powerful tool to describe our world. It formalizes the process of taking differences and taking sums. Both are natural operations. Differences measure change, sums measure how things accumulate. We are interested for example in the total amount of precipitation in Boston over a year but we are also interested in how the temperature does change over time. The process of taking differences is in a limit called derivative. The process of taking sums is in the limit called integral. These two processes are related in an intimate way. In this first lecture, we want to look at these two processes in a discrete setup first, where functions are evaluated only on integers. We will call the process of taking differences a derivative and the process of taking sums as integral.

Start with the sequence of integers

\[ 1, 2, 3, 4, \ldots \]

We say \( f(1) = 1, f(2) = 2, f(3) = 3 \) etc and call \( f \) a function. It assigns to a number a number. It assigns for example to the number 100 the result \( f(100) = 100 \). Now we add these numbers up. The sum of the first \( n \) numbers is called

\[ S_f(n) = f(1) + f(2) + f(3) + \ldots + f(n). \]

In our case we get

\[ 1, 3, 6, 10, 15, \ldots \]

It defines a new function \( g \) which satisfies \( g(1) = 1, g(2) = 3, g(2) = 6 \) etc. The new numbers are known as the triangular numbers. From the function \( g \) we can get \( f \) back by taking difference:

\[ Dg(n) = g(n) - g(n-1) = f(n). \]

For example \( Dg(5) = g(5) - g(4) = 15 - 10 = 5 \) and this is indeed \( f(5) \).

Finding a formula for the sum \( S_f \) is not so easy. The young mathematician Karl-Friedrich Gauss realized as a 7 year old kid when giving the task to sum up the first 100 numbers that it is the same as adding up 50 times 101 which is 5050. Gauss found \( g(n) = n(n+1)/2 \). He did that by pairing things up. To add up \( 1 + 2 + 3 + \ldots + 10 \) for example we can write this as \( (1 + 10) + (2 + 9) + (3 + 8) + (4 + 7) + (5 + 6) \) leading to \( n/2 \) terms of \( n + 1 \) if \( n \) is even. Taking differences again is easier \( Dg(n) = (n + 1)n/2 - n(n-1)/2 = n = f(n) \).

Lets add up the new sequence again and compute \( h = Sg \). We get the sequence

\[ 1, 4, 10, 20, 35, \ldots \]

These numbers are called the tetrahedral numbers because one use \( h(n) \) marbles to build a tetrahedron of side length \( n \). For example, we need \( h(4) = 20 \) golf balls for example to build a tetrahedron of side length 4. The formula which holds for \( h \) is \( h(n) = n(n+1)(n+2)/6 \). We see that summing the differences gives the function in the same way as differencing the sum:

\[ SDF(n) = f(n) - f(0), DSF(n) = f(n) \]
Don’t worry yet, if this is too abstract. We will come back to it again and again. But this is an arithmetic version of the fundamental theorem of calculus which we will explore in this course. The process of adding up numbers will lead to the integral \( \int_0^x f(x) \, dx \). The process of taking differences will lead to the derivative \( \frac{d}{dx} f(x) \). One of the high lights of this course is to understand the fundamental theorem of calculus:

\[
\int_0^x \frac{d}{dt} f(t) \, dt = f(x) - f(0), \quad \frac{d}{dx} \int_0^x f(t) \, dt = f(x)
\]

and see why it is such a fantastic result. You see formally that it fits the result for difference and sum. A major goal of this course will be to understand the fundamental theorem result and see its use. But we have packed the essence of the theorem in the above version with \( S \) and \( D \). It is a version which will lead us.

1 **Problem:** Given the sequence 1, 1, 2, 3, 5, 8, 13, 21, \ldots which satisfies the rule \( f(x) = f(x - 1) + f(x - 2) \). It defines a function on the positive integers. For example, \( f(6) = 8 \). What is the function \( g = Df \), if we assume \( f(0) = 0 \)? **Solution:** We take the difference between successive numbers and get the sequence of numbers

\[ 1, 0, 1, 1, 2, 3, 5, 8, \ldots \]

After 2 entries, the same sequence appears again. We can also deduce directly from the above recursion that \( f \) has the property that \( Df(x) = f(x-2) \). It is called the Fibonacci sequence, a sequence of great fame.

2 **Problem:** Take the same function \( f \) given by the sequence 1, 1, 2, 3, 5, 8, 13, 21, \ldots but now compute the function \( h(n) = Sf(n) \) obtained by summing the first \( n \) numbers up. It gives the sequence 1, 2, 4, 7, 12, 20, 33, \ldots. What sequence is that?

**Solution:** Because \( Df(x) = f(x-2) \) we have \( f(x) - f(0) = SDf(x) = Sf(x-2) \) so that \( Sf(x) = f(x + 2) - f(2) \). Summing the Fibonacci sequence produces the Fibonacci sequence shifted to the left with \( f(2) = 1 \) is subtracted. It has been relatively easy to find the sum, because we knew what the difference operation did. This example shows:

We can study differences to understand sums.

The next problem illustrates this too:

3 **Problem:** Find the next term in the sequence

\[ 2, 6, 12, 20, 30, 42, 56, 72, 90, 110, 132 \ . \]

**Solution:** Take differences

\[
\begin{array}{cccccccccccc}
2 & 6 & 12 & 20 & 30 & 42 & 56 & 72 & 90 & 110 & 132 \\
2 & 4 & 6 & 8 & 10 & 12 & 14 & 16 & 18 & 20 & 22 \\
2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{array}
\]

Now we can add an additional number, starting from the bottom and working us up.

\[
\begin{array}{cccccccccccc}
2 & 6 & 12 & 20 & 30 & 42 & 56 & 72 & 90 & 110 & 132 & 156 \\
2 & 4 & 6 & 8 & 10 & 12 & 14 & 16 & 18 & 20 & 22 & 24 \\
2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{array}
\]

In the rest of this hour, we talk about some applied and not so applied problems which involve calculus.
Homework

1. We have defined $S_f(n) = f(1) + f(2) + \ldots + f(n)$ and $D_f(n) = f(n) - f(n-1)$ and seen

$$
\begin{align*}
f(n) &= 1 & \text{we have } & g(n) = S_f(n) = n . \\
f(n) &= n & \text{we have } & g(n) = S_f(n) = n(n+1)/2. \\
f(n) &= n(n+1)/2 & \text{we have } & g(n) = S_f(n) = n(n+1)(n+2)/6. 
\end{align*}
$$

Guess a formula $g(n) = S_f(n)$ for $f(n) = n(n+1)(n+2)/6$ and verify using algebraic manipulation that it satisfies $Dg(n) = f(n)$. Can you see a pattern?

2. Find the next term in the sequence 3, 12, 33, 72, 135, 228, 357, 528, 747, 1020, 1353, \ldots. To do so, compute successive derivatives $g = Df$ of $f$, then $h = Dg$ until you see a pattern.

3. The function $f(x) = 2^x$ can first be defined on integers, then on rational numbers like $2^{(3/2)} = \sqrt{8}$. We have for example $f(0) = 1, f(1) = 2, f(2) = 4, \ldots$

a) Verify that $f$ satisfies the equation $Df(x) = f(x-1)$, where $Df(x) = f(x) - f(x-1)$.

b) The function $f(x) = 5^x$ satisfies a similar rule. Which one?

4. Find $g(n) = S_f(n)$ for the function $f(n) = n^2$. This means we want to find a formula such that $g(1) = 1, g(2) = 5, g(3) = 14$ leading to the sequence of numbers 1, 5, 14, 30, 55, 91, 140, 204, 285, \ldots.

Note that we have already have computed $S_f$ for $g(n) = n(n+1)/2$ as well as for $h(n) = n$.

Try to write $f$ as a combination of $g$ and $h$ and use the rule $D(f + g) = Df + Dg$.

5. Find a formula $g(n) = S_f(n)$ for the function $f(n) = 7^n$. First compute the ”derivative” $Df$ of $f$ and go from there.

General remarks about homework

- Make sure to think about the problem yourself first before discussing it with others.
- The time you spend on homework is valuable. Especially the exploration time before you know how to solve it.
- If you do not know how to get started, don’t hesitate to ask.
Lecture 1: Worksheet

In this first lecture, we want to see that the essence of calculus is already in basic arithmetic.

Triangular numbers

We stack disks onto each other building \( n \) layers and count the number of discs. The number sequence we get are called triangular numbers.

\[
\begin{align*}
1 & \quad 3 & \quad 6 & \quad 10 & \quad 15 & \quad 21 & \quad 36 & \quad 45 & \quad \ldots
\end{align*}
\]

This sequence defines a function on the natural numbers. For example, \( f(4) = 10 \).

1. Can you find \( f(100) \)? The task to find this number was given to Carl Friedrich Gauss in elementary school. The 7 year old came up quickly with an answer. How?

Carl-Friedrich Gauss, 1777-1855

Tetrahedral numbers

We stack spheres onto each other building \( n \) layers and count the number of spheres. The number sequence we get are called tetrahedral numbers.

\[
\begin{align*}
1 & \quad 4 & \quad 10 & \quad 20 & \quad 35 & \quad 56 & \quad 84 & \quad 120 & \quad \ldots
\end{align*}
\]

Also this sequence defines a function. For example, \( g(3) = 10 \). But what is \( g(100) \)? Can we find a formula for \( g(n) \)?

2. Once you know the formula for \( g(n) \) given to you as \( g(n) = \frac{n(n + 1)(n + 2)}{6} \), verify that it is the right one, by checking \( g(n) - g(n - 1) = \frac{n(n + 1)}{2} \).
Lecture 2: Functions

A function is a rule which assigns to a real number a new real number. An example is \( f(x) = x^2 - x \). For example, it assigns to the number \( x = 3 \) the value \( 3^2 - 3 = 6 \). A function is given with a domain \( A \), the points where \( f \) is defined and a codomain \( B \) a set of numbers in which \( f \) takes values.

Typically, the codomain agrees with the set of real numbers and the domain to be all the numbers, where the function is defined. The function \( f(x) = 1/x \) for example is not defined at \( x = 0 \) so that we chose the domain \( A = \mathbb{R} \setminus \{0\} \), all numbers except 0. The function \( f(x) = 1/x \) reaches every point in \( B \) and is invertible. It is its own inverse. Here are a few examples of functions. We will look at them in more detail during the lecture, especially the polynomials, trigonometric functions and exponential function.

| identity  | \( f(x) = x \) | power   | \( f(x) = 2^x \) |
| constant  | \( f(x) = 1 \)   | exponential | \( f(x) = e^x = \exp(x) \) |
| linear    | \( f(x) = 3x + 1 \) | logarithm | \( f(x) = \log(x) = \exp^{-1}(x) \) |
| quadratic | \( f(x) = x^2 \)  | absolute value | \( f(x) = |x| \) |
| cosine    | \( f(x) = \cos(x) \) | devil comb | \( f(x) = \sin(1/x) \) |
| sine      | \( f(x) = \sin(x) \) | bell function | \( f(x) = e^{-x^2} \) |
| exponentials | \( f(x) = \exp_h(x) = (1 + h)^{x/h} \) | witch of Agnesi | \( f(x) = \frac{1}{1 + x^2} \) |
| logarithms | \( f(x) = \log_h(x) = \exp_h^{-1} \) | sinc | \( \sin(x)/x \) |

We can build new functions by:

- add functions \( f(x) + g(x) \)
- scale functions \( 2f(x) \)
- translate \( f(x+1) \)
- compose \( f(g(x)) \)
- invert \( f^{-1}(x) \)
- difference \( f(x+1) - f(x) \)
- sum up \( f(x) + f(x+1) + \ldots \)

Here are important functions:

- polynomials \( x^2 + 3x + 5 \)
- rational functions \( (x + 1)/(x^4 + 1) \)
- exponential \( e^x \)
- logarithm \( \log(x) \)
- trig functions \( \sin(x), \tan(x) \)
- inverse trig functions \( \arcsin^{-1}(x), \arctan(x) \)
- roots \( \sqrt{x}, x^{1/3} \)

We will look at these functions a lot during this course. The logarithm, exponential and trigonometric functions are especially important.

For some functions, we need to restrict the domain, where the function is defined. For the square root function \( \sqrt{x} \) or the logarithm \( \log(x) \) for example, we have to assume that the number is positive. We write that the domain is \( (0, \infty) = \mathbb{R}^+ \). For the function \( f(x) = 1/x \), we have to assume that \( x \) is different from zero. Keep these three examples in mind.

The graph of a function is the set of points \( \{(x, y) = (x, f(x))\} \) in the plane, where \( x \) runs over the domain \( A \) of \( f \). Graphs allow us to visualize functions. We can "see them", when we draw the graph.
\[
\exp(x) \quad \log(x) \\
\frac{e^{-x^2}}{x} \quad x \cos(1/x) \\
\sqrt{x} \quad x^3 - 3x
\]
Homework

1. Draw the function \( f(x) = x + \sin(x) \). Its graph goes through the origin \((0,0)\).
   a) A function is called **odd** if \( f(-x) = -f(x) \). Is \( f \) odd?
   b) A function is called **even** if \( f(x) = f(-x) \). Is \( f \) even?
   c) A function is called **monotone increasing** if \( f(y) > f(x) \) if \( y > x \). Is \( f \) monotone increasing? You do not have to decide this yet analytically. Just draw\(^*\) the function and make up your mind.

2. A function \( f : A \to B \) is called **invertible** or **one to one** if there is another function \( g \) such that \( g(f(x)) = x \) for all \( x \) in \( A \) and \( f(g(y)) = y \) for all \( y \in B \). For example, the function \( g(x) = \sqrt{x} \) is the inverse of \( f(x) = x^2 \) as a function from \( A = [0, \infty) \) to \( B = [0, \infty) \). Determine from the following functions whether they are invertible. If they are invertible, find the inverse.
   a) \( f(x) = \sin(x) \) from \( A = [0, \pi/2] \) to \( B = [0, 1] \)
   b) \( f(x) = x^3 \) from \( A = \mathbb{R} \) to \( B = \mathbb{R} \)
   c) \( f(x) = x^6 \) from \( A = \mathbb{R} \) to \( B = \mathbb{R} \)
   d) \( f(x) = \exp(5x) \) from \( A = \mathbb{R} \) to \( B = \mathbb{R}^+ = (0, \infty) \).
   e) \( f(x) = 1/(1 + x^2) \) from \( A = [0, \infty) \) to \( B = [0, \infty) \).

3. Look at the function \( f_1(x) = \sin(x), f_2(x) = \sin(\sin(x)), f_3(x) = \sin(\sin(\sin(x))) \).
   a) Draw the graphs of the functions \( f_1, f_2, f_3 \) on the interval \([0, 4\pi]\).
   b) Can you imagine what \( f_{100000}(x) \) looks like? You might want to make more experiments here to see the answer. Of course you are allowed to plot the functions with a calculator or with an online grapher like Wolfram alpha. (The weblink can be found below).

4. Let's call a function \( f(x) \) a **composition square root** of a function \( g \) if \( f(f(x)) = g(x) \). For example, the function \( f(x) = x^2 + 1 \) is the composition square root of \( g(x) = x^4 + 2x^2 + 2 \) because \( f(f(x)) = (x^2 + 1)^2 + 1 = g(x) \). Find the composition square roots of the following functions:
   a) \( f(x) = \sin(\sin(x)) \).
   b) \( f(x) = x^4 \)
   c) \( f(x) = x \)
   d) \( f(x) = x^4 + 2x^2 + 2 \)
   e) \( f(x) = e^{e^x} \).
   Note that it can be difficult in general to find the square root function in general. Already for basic functions like \( \exp(x) \) or \( \sin(x) \), we are speechless.

5. A function \( f(x) \) has a **root** at \( x = a \) if \( f(a) = 0 \). Roots are places, where the function is zero. Find one root for each of the following functions or state that there is none.
   a) \( f(x) = \sin(x) \)
   b) \( f(x) = \exp(x) \)
   c) \( f(x) = x^3 - x \)
   d) \( f(x) = \sin(x)/x - 1 \)
   e) \( f(x) = \csc(x) = 1/\sin(x) \)

\(^*\) Here is how you can use the Web to plot a function. The example given is \( \sin(x) \).
Lecture 2: Worksheet

In this lecture, we want to learn what a function is and get acquainted with the most important examples.

Trigonometric functions

The cosine and sine functions can be defined geometrically by the coordinates \((\cos(x), \sin(x))\) of a point on the unit circle. The tangent function is defined as \(\tan(x) = \sin(x)/\cos(x)\).

\[
\begin{align*}
\cos(x) &= \text{adjacent side/hypothenuse} \\
\sin(x) &= \text{opposite side/hypothenuse} \\
\tan(x) &= \text{opposite side/adjacent side}
\end{align*}
\]

Pythagoras theorem gives us the important identity

\[
\cos^2(x) + \sin^2(x) = 1
\]

Define also \(\cot(x) = 1/\tan(x)\). Less important but sometimes used are \(\sec(x) = 1/\cos(x)\), \(\csc(x) = 1/\sin(x)\).

1. Find \(\cos(\pi/3), \sin(\pi/3)\).
2. Where does \(\cos\) and \(\sin\) have roots, places, where the function is zero?
3. Find \(\tan(3\pi/2)\) and \(\cot(3\pi/2)\).
4. Find \(\cos(3\pi/2)\) and \(\sin(3\pi/2)\).

5. Find \(\tan(\pi/4)\) and \(\cot(\pi/4)\).
The exponential function

The function $2^x$ is first of all defined for all integers like $2^{10} = 1024$. By taking roots, we can define it for rational numbers like $2^{3/2} = 8^{1/2} = \sqrt{8} = 2.828...$. Since the function $2^x$ is monotonone on the set of rationals, we can fill the gaps and define the function $2^x$ for any $x$. By taking square roots again and again, we see $2^{1/2}, 2^{1/4}, 2^{1/8}, ...$ we approach $2^0 = 1$.

and define the exponential $a^x$. It satisfies $a^0 = 1$ and the remarkable rule:

$$a^{x+y} = a^x \cdot a^y$$

It is spectacular because it provides a link between addition and multiplication.

We will especially consider the exponential $[\exp_h(x) = (1 + h)^{x/h}]$, where $h$ is a positive parameter. This is a supercool exponential because it satisfies $\exp_h(x + h) = (1 + h) \exp_h(x)$ so that

$$[\exp_h(x + h) - \exp_h(x)]/h = \exp_h(x).$$

Hold on to that. We will look at this later again. In modern language, we would say that "the quantum derivative of the quantum exponential is the function itself for any Planck constant $h$".

For $h = 1$, we have the function $2^x$ we have started with. In the limit $h \to 0$, we get the important exponential function $\exp(x)$ which we also call $e^x$. For $x = 1$, we get the Euler number $e = e^1 = 2.71828...$.

1. What is $2^{-5}$?
2. Find $2^{1/2}$.
3. Find $2^{1/3}$.
5. Assume $h = 2$ find $\exp_h(4)$.
Lecture 3: Limits

Sometimes, functions look as if they are not defined at some point. They often allow a continuation to "non-allowed" places however. Let's look at some examples:

1. The function \( f(x) = \frac{x^3 - 1}{x - 1} \) is at first not defined at \( x = 1 \). However, for \( x \) close to \( 1 \), nothing really bad happens. We can evaluate the function at points closer and closer to \( 1 \) and get closer and closer to \( 3 \). We will say \( \lim_{x \to 1} f(x) = 3 \). Indeed, as you might have seen already, we have \( f(x) = x^2 + x + 1 \) by factoring out the term \( x - 1 \). While the function was initially not defined at \( x = 1 \), we can assign a natural value \( 3 \) at the point \( x = 1 \) and keep a "nice" function. The graph will continue nicely through that point.

Definition. We write \( x \to a \) if we mean that the number \( x \) approaches \( a \) from either side. A function \( f(x) \) has a limit at a point \( a \) if there exists \( b \) such that \( f(x) \to b \) for \( x \to a \). We write \( \lim_{x \to a} f(x) = b \). It should not matter, whether we approach \( a \) from the left or from the right. In both cases, we should get the same limiting value \( b \).

2. The function \( f(x) = \sin(x)/x \) is called sinc\((x)\). It converges to \( 1 \) as \( x \to 0 \). We can see this geometrically by comparing the side \( a = \sin(x) \) of a right angle triangle with a small angle \( \alpha = x \) and hypotenuse \( 1 \) with the length of the arc between \( B, C \) of the unit circle centered at \( A \). The arc has length \( x \) which is close to \( \sin(x) \) for small \( x \). Keep this example in mind. It is a good one. Remark. It is possible to see this analytically. A computer for example approximates the function \( \sin(x) \) with the polynomial \( x - x^3/3! + x^5/5! - \cdots + x^{100}/100! \) and if we divide this by \( x \), we get \( 1 - x^2/3! + x^4/5! - \cdots + x^{99}/100! \) which converges to \( 1 \) as \( x \) approaches \( 0 \).

3. The quadratic function \( f(x) \) has the property that \( f(x) \) approaches \( 4 \) if \( x \) approaches \( 2 \). This is a very typical case. To evaluate functions at a point, we do not have to take a limit. The function is already defined there. This is important: given a typical function, most points are "healthy". We do not have to worry about limits there. In most cases we see in real applications we only have to worry about limits when the function divides by \( 0 \). For example \( f(x) = (x^4 + x^2 + 1)/x \) needs to be investigated carefully only at \( x = 0 \). You see for example that for \( x = 1/1000 \), the function is slightly larger than \( 1000 \), for \( x = 1/1000000 \) it is larger than one million. There is no rescue here. The limit does not exist at \( 0 \).

4. More generally, for all polynomials, the limit \( \lim_{x \to a} f(x) = f(a) \) is defined. We do not have to worry about limits, if we deal with polynomials.

5. For all trigonometric polynomials involving sin and cos, the limit \( \lim_{x \to a} f(x) = f(a) \) is defined. We do not have to worry about limits if we deal with trigonometric polynomials like \( \sin(3x) + \cos(5x) \). The function \( \tan(x) \) however has no limit at \( x = \pi/2 \). There is no value \( b \) we can find so that \( \tan(\pi/2 + h) \to b \) for \( h \to 0 \). This is due to the fact that \( \cos(x) \) is zero at \( \pi/2 \). We have \( \tan(x) \) goes to \( +\infty \) "plus infinity" for \( x \searrow \pi/2 \) and \( \tan(x) \) goes to \( -\infty \) for \( x \nearrow \pi/2 \). In the first case, we approach \( \pi/2 \) from the right and in the second case from the left.

6. The cube root function \( f(x) = x^{1/3} \) converges to \( 0 \) as \( x \to 0 \). For \( x = 1/1000 \) for example, we have \( f(x) = 1/10 \) for \( x = 1/n^3 \) the value \( f(x) \) is \( 1/n \). The cube root function is defined everywhere on the real line, like \( f(-8) = -2 \) and is continuous everywhere.
Why do we worry about limits at all? One of the main reasons will be that we will define the derivative and integral using limits. But we will also use limits to get numbers like $\pi = 3.1415926, \ldots$. In the next lecture, we will look at the important concept of continuity, which involves limits too.

**Figure:** We can test whether a function has the limit $b$ at a point $a$ if for every vertical interval $I$ containing $b$ there exists a horizontal interval $J$ containing $a$ such that if $x$ is in $J$, then $f(x)$ is in $I$. If the function stays bounded, does not oscillate at the point like $\sin(1/x)$ or jump, then the limit exists.

**Figure:** We see here the function $f(x) = \arctan(\tan(x) + 1)$, where $\arctan$ is the inverse of $\tan$ giving the angle from the slope. In this case, the limit does not exist for $a = \pi/2$. If we approach this point $a$ from the right, we are always far below the limiting value. The limit exists from the left if we postulate $f(\pi/2) = \pi/2$. Note that $f$ has a priori no value at $x = \pi/2$ because $\tan(x)$ becomes infinite there.
Problem: Determine from the following functions whether the limits \( \lim_{x \to 0} f(x) \) exist. If the limit exists, find it.

a) \( f(x) = \frac{\cos(x)}{\cos(2x)} \)
b) \( f(x) = \tan(x)/x \)
c) \( f(x) = \frac{x^2 - x}{(x - 1)} \)
d) \( f(x) = \frac{x^4 - 1}{(x^2 - 1)} \)
e) \( f(x) = \frac{x + 1}{(x - 1)} \)
f) \( f(x) = \frac{x}{\sin(x)} \)
g) \( f(x) = \frac{\sin(x)}{x^2} \)
h) \( f(x) = \frac{\sin(x)}{\sin(2x)} \)

Solution: a) There is no problem at \( x = 0 \). Both, the nominator and denominator converge to 1. The limit is 1.
b) This is \( \text{sinc}(x)/\cos(x) \). There is no problem at \( x = 0 \) for \( \text{sinc} \) nor for \( 1/\cos(x) \). The limit is 1.
c) We can heal this function. It is the same as \( x + 1 \). The limit is 1.
d) We can heal this function. It is the same as \( x^2 + 1 \). The limit is 1.
e) There is no problem at \( x = 0 \). There is mischief at \( x = 1 \) although but that is far, far away. At \( x = 0 \), we get 1.
f) This is the prototype. We know that the limit is 1.
g) This limit does not exist. Because it is \( \text{sinc}(x)/x \). Because \( \text{sinc}(x) \) converges to 1. we are in trouble when dividing again by \( x \). There is no limit.
h) We know \( \sin(x)/x \to 1 \) so that also \( \sin(2x)/(2x) \) has the limit 1. If we divide them, see \( \sin(x)/\sin(2x) \to 1/2 \). The result is 1/2.
# Homework

1. a) Draw the graph of the function
   \[ f(x) = \frac{(1 - \cos(x))}{x^2}. \]
   b) Where is the function \( f \) defined? Can you find the limit at the places, where it is not defined?
   c) A function is **even** if \( f(x) = f(-x) \), odd if \( f(x) = -f(x) \). Is \( f \) even or odd, or neither?
   d) What happens with the function \( f \) in the limit \( x \to +\infty \) and \( x \to -\infty \)?

2. Find the limits of each of the following functions at the point \( x \to 0 \):
   a) \( f(x) = (x^4 - 1)/(x - 1) \)
   b) \( f(x) = \sin(3x)/x \)
   c) \( f(x) = \sin(5x)/x \)
   d) \( f(x) = \sin(3x)/\sin(5x) \)

3. a) Can you see the limit of \( g(h) = [f(x+h) - f(x)]/h \) as a function of \( h \) at the point \( x = 0 \) for the function \( f(x) = \sin(x) \)?
   b) Verify that the function \( f(x) = \exp_h(x) = (1+h)^{x/h} \) satisfies \( [f(x+h) - f(x)]/h = f(x) \). We define \( e^x = \exp(x) = \lim_{h \to 0} \exp_h(x) \).

4. Find the limits for \( x \to 0 \):
   a) \( f(x) = (x^2 - 2x + 1)/(x - 1) \).
   b) \( f(x) = 2^x \).
   c) \( f(x) = 2^{2x} \).
   d) \( f(x) = \sin(\sin(x))/\sin(x) \).

5. We explore in this problem the limit of the function \( f(x) = x^x \) if \( x \to 0 \). Can we find a limit? Take a calculator or use Wolfram α and experiment. What do you see when \( x \to 0 \)? Optional: can you find a explanation for your experiments?
Lecture 3: Worksheet

We study a few limits.

The Sinc function

A prototype function for studying limits is the sinc function
\[ f(x) = \frac{\sin(x)}{x}. \]

It is an important function and appears in many applications like in the study of waves or signal processing (it is used in low pass filters).

The name sinc comes from its original latin name sinus cardinalis.

1. Does the function \( \frac{\cos(x)}{x} \) have a limit at \( x \to 0 \)?

2. Does the function \( \frac{\sin(x^2)}{x^2} \) have a limit for \( x \to 0 \)?

3. Does the function \( \frac{\sin(x^2)}{x} \) have a limit for \( x \to 0 \)?

4. Does the function \( \frac{\sin^2(x)}{x^2} \) have a limit for \( x \to 0 \)?

5. Does the limit \( \frac{1 - \cos^2(x)}{x^2} \) exist for \( x \to 0 \)?

6. Does the function \( \frac{x}{\sin(x)} \) have a limit for \( x \to 0 \)?

7. Does the function \( \frac{\sin(x)}{|x|} \) have a limit for \( x \to 0 \)?

8. Does the function \( \frac{\sin(x)}{\sqrt{|x|}} \) have a limit for \( x \to 0 \)?
Lecture 4: Continuity

A function $f$ is called **continuous** at a point $p$ if a value $f(p)$ can be found such that $f(x) \rightarrow f(p)$ for $x \rightarrow p$. A function $f$ is called **continuous on** $[a,b]$ if it is continuous for every point $x$ in the interval $[a,b]$.

In the interior $(a,b)$, the limit needs to exist both from the right and from the left. At the boundary $a$ only the right limit needs to exist and at $b$ only the left limit. Intuitively, a function is continuous if you can **draw the graph of the function without lifting the pencil**. Continuity means that small changes in $x$ results in small changes of $f(x)$.

1. Any polynomial is continuous everywhere. To see this note that the sum of two continuous functions is continuous and that a multiple of a continuous function is continuous. Since $x^n$ is continuous for all $n$, and every polynomial is a sum of multiples of such functions, we have continuity in general.

2. The function $f(x) = 1/x$ is continuous everywhere except at $x = 0$. It is a prototype of a function which is not continuous due to a **pole**. The source for the trouble is the division by zero which would happen if we would try to evaluate the function at $x = 0$.

3. The function $\csc(x) = 1/\sin(x)$ is not continuous at $x = 0, x = \pi, x = 2\pi$ and any multiple of $\pi$. It has poles there because $\sin(x)$ is zero there and because we would divide by zero at such points.

4. The function $f(x) = \sin(\pi/x)$ is continuous everywhere except at $x = 0$. It is a prototype of a function which is not continuous due to **oscillation**. We can approach $x = 0$ in ways that $f(x_n) = 1$ and such that $f(z_n) = -1$. Just chose $x_n = 2/(4k+1)$ and $z_n = 2/(4k-1)$.

5. The **signum function** $f(x) = \text{sign}(x) = \begin{cases} 1 & x > 0 \\ -1 & x < 0 \\ 0 & x = 0 \end{cases}$ is not continuous at 0. It is a prototype of a function which has a **jump** discontinuity at 0.

We can refine the notion of continuity and say that a function is **continuous from the right**, if there exists a limit from the right $\lim_{x \downarrow a} f(x) = b$. Similarly a function $f$ can be continuous from the left only. Most of the time we mean with ”continuous”= ”continuous on the real line”.

**Rules:**

- a) If $f$ and $g$ are continuous, then $f + g$ is continuous.
- b) If $f$ and $g$ are continuous, then $f \times g$ is continuous.
- c) If $f$ and $g$ are continuous and if $g > 0$ then $f/g$ is continuous.
- d) If $f$ and $g$ are continuous, then $f \circ g$ is continuous.

6. $\sqrt{x^2 + 1}$ is continuous everywhere on the real line.
7 \cos(x) + \sin(x) \text{ is continuous everywhere.}

8 The function \( f(x) = \log(|x|) \) is continuous everywhere except at 0. Indeed since for every integer \( n \), we have \( f(e^{-n}) = -n \), this can become arbitrarily large for \( n \to \infty \) even so \( e^{-n} \) converges to 0 for \( n \) running to infinity.

9 While \( \log(|x|) \) is not continuous at \( x = 0 \), the function \( \frac{1}{\log |x|} \) is continuous at \( x = 0 \). Is it continuous everywhere?

10 The function \( f(x) = \frac{\sin(x + h) - \sin(x)}{h} \) is continuous for every \( h > 0 \). We will see next week that nothing bad happens when \( h \) becomes smaller and smaller and that the continuity will not deteriorate. Indeed, we will see that we get closer and closer to the \( \cos \) function.

There are three major reasons, why a function is not continuous at a point: it can jump, oscillate or escape to infinity. Here are the prototype examples. We will look at more during the lecture.

Why do we like continuity? We will see many reasons during this course but for now lets just say that:

A wild continuous function. This Weierstrass function is believed to be a fractal.

"Continuity tames a function. It can be pretty wild, but not too crazy."

A crazy discontinuous function. It is discontinuous at every point and known to be a fractal.
Continuity will be useful later for extremization. A continuous function on an interval \([a, b]\) has a maximum and minimum. And if a continuous function is negative at some place and positive at an other, there is a point between, where it is zero. These are all useful properties to have and they do not hold if a function is not continuous.

11 **Problem** Determine from each of the following functions, where discontinuities appear and give a short reason.

a) \(f(x) = \log(|x^2 - 1|)\)
b) \(f(x) = \sin(\cos(\pi/x))\)
c) \(f(x) = \cot(x) + \tan(x) + x^4\)
d) \(f(x) = x^4 + 5x^2 - 3x + 4\)
e) \(f(x) = \frac{x^2 - x}{x}\)

**Solution.**

a) \(\log(|x|)\) is continuous everywhere except at \(x = 0\). Since \(x^2 - 1 = 0\) for \(x = 1\) or \(x = -1\), the function \(f(x)\) is continuous everywhere except at \(x = 1\) and \(x = -1\).

b) The function \(\pi/x\) is continuous everywhere except at \(x = 0\). Therefore \(\cos(\cos(\pi/x))\) is continuous everywhere except possibly at \(x = 0\). We have still to investigate the point \(x = 0\) but there, the function \(\cos(\pi/x)\) takes values between \(-1\) and \(1\) for points arbitrarily close to \(x = 0\). The function \(f(x)\) takes values between \(\sin(-1)\) and \(\sin(1)\) arbitrarily close to \(x = 0\). It is not continuous there.

c) The function \(x^4\) is continuous everywhere. We do not have to consider it. The function \(\tan(x)\) is continuous everywhere except at the points points \(k\pi\), integer multiples of \(\pi\). The function \(\cot(x)\) is continuous everywhere except at points \(\pi/2 + k\pi\). The function \(f\) is therefore continuous everywhere except at the point \(x = k\pi/2\), multiples of \(\pi/2\).

d) The function is a polynomial. We know that polynomials are continuous everywhere.

e) The function is continuous everywhere except at \(x = 0\), where we have to look at the function more closely. But we can heal the function by dividing nominator and denominator by \(x\) which is possible for \(x\) different from \(0\). We get \(x - 1\).

**Homework**

1 On which intervals is the following function continuous?
For the following functions, determine the points, where $f$ is not continuous.

a) $f(x) = \tan(1 - x)$
b) $x \cos(1/x)$
c) $\text{sign}(x)/x$
d) $\text{sinc}(x) + \sin(x) + x^8 + \log(x)$
e) $\frac{x^2 + 5x + x^4}{x - 1}$

State which kind of discontinuity appears.

Construct a function which has a jump discontinuity, an oscillatory one as well as an escape to infinity. Can you construct an example where two of these flaws happen at the same point? Can you even construct an example where all three happen at the same point?

Heal the following functions:

a) $\frac{x^5 - 32}{x^2 - 2}$
b) $x^5 - x^3/(x^2 - 1)$
c) $((\sin(x))^3 - \sin(x))/\sin(x)$.
d) $(x^3 + 3x^2 + 3x + 1)/(x^2 + 2x + 1)$
e) $(x^{1000} - 1)/(x^{100} - 1)$

Is the following function continuous?

$$\frac{\cos(\cos(\cos(\cos(\cos(x)))))}{\sin(\sin(\sin(\sin(e^{e^{e^{e^{e^x}}}}))))}$$

$$\log(2x+1) + 2 + \cos((x))$$
Lecture 4: Worksheet

Whats good and whats bad?

We have seen that oscillation, poles and jumps are the perils for continuity. In general, we do not have to worry about continuity. There are very few mechanisms which bring you in peril. A function can either start to oscillate like mad, rush to infinity or jump. All cases are usually due to division by zero somewhere.

Which functions are continuous?

Which of the following functions are continuous?

1. Is $f(x) = \sqrt{|x|}$ continuous at $x = 0$?
2. Is $f(x) = \frac{1}{\sqrt{|x|}}$ continuous at $x = 0$?
3. Is $\frac{1}{\log |x^2|}$ continuous at $x = 0$?
4. Is $\log(\log |x|)$ continuous at $x = 0$?
5. Is $1/(1 + 1/(x^4 + 1))$ continuous everywhere?
6. Is $\sin(\sec(x))$ continuous everywhere?

Enemy of continuity

Oscillations, escape to infinity and jumps are reasons for discontinuity.
Lecture 5: Intermediate Value Theorem

If \( f(a) = 0 \), then the value \( a \) is called a root of \( f \). For example, \( f(x) = \cos(x) \) has the root \( x = \pi/2 \).

1. \( f(x) = 4x + 6 \). Find the roots of \( f \). Answer: set the function equal to 0 and solve for \( x \). We get \( 4x + 6 = 0 \).

2. \( f(x) = x^2 + 2x + 1 \). Find the roots of \( f \). Answer: we can write \( f(x) = (x + 1)^2 \). The function has the root \( x = -1 \).

3. \( f(x) = (x - 2)(x + 6)(x + 3) \). Find the roots of \( f \).

4. \( f(x) = 12 + x - 13x^2 - x^3 + x^4 \). Find the roots of \( f \). We do not have a formula for this, but we can try. Indeed, we see that for \( x = 1 \), \( x = -3 \), \( x = 4 \), \( x = -1 \) we have roots.

5. \( f(x) = \exp(x) \). This function does not have any root.

6. \( f(x) = 2^x - 16 \). The root \( x = 2 \).

**Intermediate value theorem of Bolzano.** If \( f \) is continuous on \([a, b]\) and \( f(a), f(b) \) have different signs, there is a root of \( f \) in \((a, b)\).

Proof. We can assume \( f(a) < 0 \) and \( f(b) > 0 \). The other case is similar. Look at the point \( c = (a + b)/2 \). If \( f(c) < 0 \), then look take \([c, b]\) as your new interval, otherwise, take \([a, c]\). We get a new root problem on a smaller interval. Repeat the procedure. After \( n \) steps, the search is narrowed to an interval \([u_n, v_n]\) of size \( 2^{-n}(b - a) \). Continuity assures that \( f(u_n) - f(v_n) \to 0 \) and \( f(u_n), f(v_n) \) have different signs. Both \( u_n, v_n \) converge to a root of \( f \).

7. The function \( f(x) = x^{17} - x^5 + x^3 + 5x^2 + \sin(x) \) has a root. Solution. The function goes to \(+\infty\) for \( x \to \infty \) and to \(-\infty\) for \( x \to -\infty \). We have for example \( f(10000) > 0 \) and \( f(-1000000) < 0 \). The intermediate value theorem assures there is a point where \( f(x) = 0 \).

8. There is a solution to the equation \( x^r = 10 \). Solution: for \( x = 1 \) we have \( x^r = 1 \) for \( x = 10 \) we have \( x^r = 10^{10} > 10 \). Apply the intermediate value theorem.

9. There exists a point on the earth, where the temperature is the same as the temperature on its antipode. Solution: Let's draw a meridian through the north and south pole and let \( f(x) \) be the temperature on that circle. Define \( g(x) = f(x) - f(x + \pi) \). If this function is zero on the north pole, we have found our point. If not, \( g(x) \) different signs on the north and south pole. There exists therefore a point, where the temperature is the same.

10. **Wobbly Table Theorem.** On an arbitrary floor, a square table can be turned so that it does not wobble any more.

Why? The 4 legs ABCD are on a square. Let \( x \) be the angle of the line \( AC \) with with some coordinate axes if we look from above. Given the angle \( x \), we can position the table uniquely as follows: the center of ABCD is on the z-axes, the legs ABC are on the floor and AC points in the direction \( x \). Let \( f(x) \) denote the height of the fourth leg \( D \) from the ground. If we find an angle \( x \) such that \( f(x) = 0 \), we have a position where all four legs are on the ground. Assume \( f(0) \) is positive. (If it is negative, the argument is similar.) Tilt the table around the line AC so that the two legs BD have the same vertical distance \( h \) from the ground. Now translate the table down by \( h \). This does not change the angle \( x \) nor the center of the table. The two previously hovering legs BD now touch the ground and the two others AC are below. Now rotate around BD so that the third leg C is on the ground. The rotations and lowering procedures have not changed the location of the center of the table nor the direction. This position is the same as if we had turned the table by \( \pi/2 \). Therefore \( f(\pi/2) < 0 \). The intermediate value theorem assures that \( f \) has a root between 0 and \( \pi/2 \).

Define \( Df(x) = (f(x+h) - f(x))/h \). Lets call it the derivative of \( f \) for the constant \( h \). We will study it more in the next lecture. But you have verified for example \( D \exp_b(x) = \exp_b(x) \) in a homework.

Let's call a point \( p \), where \( Df(x) = 0 \) a critical point for \( h \). Lets call a point \( a \) a local maximum if \( f(a) \geq f(x) \) in an open interval containing \( a \). Define similarly a local minimum as a point where \( f(a) \leq f(x) \).

11. The function \( f(x) = x(x-h)(x-2h) \) has the derivative \( Df(x) = 3x(x-h) \) as you have verified in the case \( h = -1 \) in the first lecture of this course in a worksheet. We will write \( [x]^3 = x(x-h)(x-2h) \) and \( [x]^2 = x(x-h) \). The computation just done tells that \( D[x]^3 = 3[x]^2 \). Since \( [x]^2 \) has exactly two roots 0, \( h \), the function \( [x]^3 \) has exactly 2 critical points.

12. More generally for \( [x]^{n+1} = x(x-h)(x-2h)...(x-nh) \) we have \( D[x]^{n+1} = (n+1)[x]^n \). Because \([x]^n\) has exactly \( n \) roots, the function \([x]^{n+1}\) has exactly \( n \) critical points. Keep the formula

\[
D[x]^n = n[x]^{n-1}
\]

in mind!

13. The function \( \exp_b(x) = (1 + h)^{x/h} \) satisfies \( D\exp_b(x) = \exp_b(x) \). Because this function has no roots and the derivative is the function itself, the function has no critical points. Indeed, this function is monotone.
Figure: We see the function \( f(x) = x(x - h)(x - 2h)(x - 3h) \) with \( h = 0.5 \). This function has 3 critical points because \( D[x] = 4x^3 \) and \( x^3 \) has roots at 0, \( 0.5 \), \( 1 \). There are three local maxima or minima according to the theorem.

Later in the course, we will look at the derivative \( Df \) in the limit when \( h \to 0 \). And then the critical points are places where the tangent is horizontal. In our case now, a critical point is a point so that if we walk by a step \( h \) to the right, the function does not change. For now, just remember the formula \( D[x]^n = n[x]^{n-1} \). It will be the same formula later on when we go to the limit \( h \to 0 \).

Critical points lead to extrema as we will see later in the course. In our discrete setting we can say:

**Fermat’s maximum theorem** If \( f \) is continuous and has a critical point \( a \) for \( h \), then \( f \) has either a local maximum or local minimum inside the open interval \((a, a + h)\). Look at the range of the function \( f \) restricted to \([a, a + h]\). It is a bounded interval \([c, d]\) by the intermediate value theorem. There exists especially a point \( u \) for which \( f(u) = c \) and a point \( v \) for which \( f(v) = d \). These points are different if \( f \) is not constant on \([a, a + h]\). There is therefore one point, where the value is different than \( f(a) \). If it is larger, we have a local maximum. If it is smaller we have a local minimum.

**Problem.** Verify that a cubic polynomial has maximally 2 critical points. **Solution** \( f(x) = ax^3 + bx^2 + cx + d \). Because the \( x^3 \) terms cancel in \( f(x + h) - f(x) \), this is a quadratic polynomial. It has maximally 2 roots.

### Homework

1. Find the roots for \( f(x) = -30 + 49x - 19x^2 - x^3 + x^4 \)
2. Use the intermediate value theorem to find a root of \( f(x) = x^2 - 6x + 8 \) on \([0, 3]\). Are all roots in this interval?
3. a) Argue why there was a time, when Lady Gaga’s height was exactly 1 meter and not one mm more or less.
   b) And that there was a time, when she weighed 50 kg and not a milligram more or less.
   c) Was there a time, when she owned exactly 1’000’000 dollars and not one dime more or less?
4. Argue why there is a solution to
   a) \( \cos(x) = x \).
   b) \( \exp(x) = x \).
   c) \( \text{sinc}(x) = x^4 \).
5. a) Draw the graph of \( f(x) = x^3 - x \).
   b) Locate the local maxima and minima.
   c) Find the critical points of \( f \) to the constant \( h = 1 \). That means, find the places, where \( f(x + 1) - f(x) = 0 \).
   d) For every point \( a \) you have found in c), verify that there is a local maximum or minimum in \([a, a + 1]\).
Lecture 5: Worksheet

Its groundhog day and a blizzard is coming. We study extrema and the intermediate value theorem.

The intermediate value theorem

1. Today on groundhog day, the average temperature is 33° Fahrenheit. Last summer, there was an average temperature was 77.2°. Was there a time between July 1, 2010 and Feb 2, 2011, when the temperature was exactly 50°?

2. We have got 38 inches of snow this month already. Does this mean there was a time that we had 20 inches of snow on the ground?

3. Is there a point \( x \), where \( 1/\sin(x) = 1/2 \)? Why does the intermediate value theorem not give such a point? We have \( 1/\sin(\pi/2) = 1 \) and \( 1/\sin(3\pi/2) = -1 \).

4. Is there a point, where \( \text{sign}(x) = 1/2 \)? Remember the signum function. It is 1 for positive numbers, 0 for 0 and \(-1\) for negative numbers.

5. Lets call the function \( f(x) = x - \text{floor}(x) \) the ground hog function. If you know the movie with Bill Murray, you know why. Can you find an interval on which the intermediate value theorem fails?

The derivative and extrema

6. Find a concrete function which has only one local maximum, and no local minimum.

7. We have seen a remarkable theorem assuring the existence of maxima and minima. In the classical sense this is not true. We will define critical points as points, where \( f'(x) = 0 \) and see that for \( f(x) = x^3 \), the derivative is \( 3x^2 \) which is zero at \( x = 0 \). Does \( f(x) \) have a local maximum or minimum at \( x = 0 \)?
Lecture 6: Some examples

Here are some worked out examples, similar to what we expect you to do for the homework of lecture 6: The homework should be straightforward, except when finding $Sf(x)$, we want to add a constant such that $Sf(0) = 0$. In general, you will not need to evaluate functions and can leave terms like $\sin(5x)$ as they are. If you have seen calculus already, then you could do this exercise by writing
\[
\frac{d}{dx}f(x)
\]
instead of $Df(x)$ and by writing
\[
\int_0^x f(x) \, dx
\]
instead of $Sf(x)$. We did not introduce the derivative $d f/dx$ nor the integral $\int x$ yet. For now, just use the Differentiation rules and integrations rules in the box to the right to solve the problem.

1 Problem: Find the derivative $Df(x)$ of the function
\[
f(x) = \sin(5 \cdot x) + x^7 + 3.
\]
Answer: From the differentiation rules, we know $Df(x) = 5 \cos(5 \cdot x) + 7x^6$.

2 Problem: Find the derivative $Df(0)$ of the same function
\[
f(x) = \sin(5 \cdot x) + 5x^7 + 3.
\]
Answer: We know $Df(x) = 5 \cos(5 \cdot x) + 35x^6$. Plugging in $x = 0$ gives $5$.

3 Problem: Find the integral $Sf(x)$ of the function
\[
f(x) = \sin(5 \cdot x) + 5x^7 + 3.
\]
Answer: From the integration rules, we know $Sf(x) = -\cos(5 \cdot x)/5 + 5x^8/8 + 3x$.

4 Problem: Find the integral $Sf(1)$ of the function
\[
f(x) = x^2 + 1.
\]
Answer: From the integration rules, we know $Sf(x) = x^3/3 + x$. Plugging in $x = 1$ gives $4$ if we use the functions in the limit $h \to 0$. For positive $h$, we have to evaluate $x(x-h)(x-2h)/3 + x$ for $x = 1$ which is $(1-h)(1-2h)/3 + 1$

5 Problem: Find the integral $Sf(1)$ of the function
\[
f(x) = \exp(4 \cdot x).
\]
Answer: From the integration rules, we know $Sf(x) = \exp(4 \cdot x)/4 - 1/4$. We have added a constant such that $Sf(0) = 0$. Plugging in $x = 1$ gives $\exp(4)/4 - 1/4$.

6 Problem: Assume $h = 1/1000$. Determine the value of
\[
\frac{1}{1000} [f(0) + f(1/1000) + \ldots + f(999/1000)]
\]
for the function
\[
f(x) = -\sin(7x) + \exp(3x).
\]
Answer: The problem asks for $Sf(1)$. We first compute $Sf(x)$ taking care that $Sf(0) = 0$.
\[
Sf(x) = \cos(7x)/7 + \exp(3x)/3 - (1/7 + 1/3) .
\]
Now plug in $x = 1$ to get $\cos(7)/7 + \exp(3)/3 - (1/7 + 1/3)$.
Math 1A: Introduction to Functions and Calculus

Lecture 6: Fundamental Theorem

Calculus is the theory of differentiation and integration. We fix here a positive constant \( h \) and take differences and sums. Without taking limits, we prove a version of the fundamental theorem of calculus and differentiate and integrate polynomials, exponentials and trigonometric functions.

Given a function, define the differential quotient

\[
Df(x) = \frac{(f(x + h) - f(x))}{h}
\]

If \( f \) is continuous then \( Df \) is a continuous function too. We call it also "derivative".

1. Let’s take the constant function \( f(x) = 5 \). We get \( Df(x) = (f(x + h) - f(x))/h = (5 - 5)/h = 0 \) everywhere. We see that in general if \( f \) is a constant function, then \( Df(x) = 0 \).

2. \( f(x) = 3x \). We have \( Df(x) = (f(x + h) - f(x))/h = (3(x + h) - 3x)/h \) which is \( 3 \).

3. If \( f(x) = ax + b \), then \( Df(x) = 2a \).

For constant functions, the derivative is zero. For linear functions, it is the slope.

4. For \( f(x) = x^2 \) we compute \( Df(x) = ((x + h)^2 - x^2)/h = (2hx + h^2)/h \) which is \( 2x + h \).

5. Compute \( Sf(x) \) for \( f(x) = 1 \). Solution: We have \( Sf(x) = 0 \) for \( x \leq h \), and \( Sf(x) = h \) for \( h \leq x < 2h \) and \( Sf(x) = 2h \) for \( 2h \leq x < 3h \). In general \( S1(jh) = j \) and \( S1(x) = kh \) where \( k \) is the largest integer such that \( kh < x \). The function \( g \) grows linearly but quantized steps.

The difference \( Df \) will become the derivative \( f'(x) \).
The sum \( Sf \) will become the integral \( \int_a^x f(t) \, dt \).

\( Df \) means rise over run and is close to the slope of the graph of \( f \).
\( Sf \) means areas of rectangles and is close to the area under the graph of \( f \).

6. For \( f(x) = [x]_h^n = x(x - h)(x - 2h)\cdot \cdot \cdot (x - mh + h) \) we have

\[
f(x + h) - f(x) = (x(x - h)(x - 2h)\cdot \cdot \cdot (x - kh + h) - (x(x - h)(x - 2h)\cdot \cdot \cdot (x - mh + h)) = [x]^{m-1}h^m
\]

and so \( D[x]_h^m = m[x]_h^{m-1} \). Let’s leave the \( h \) away to get the important formula \( D[x]^m = m[x]^{m-1} \).

We can establish from this differentiation formulas for polynomials.

7. If \( f(x) = [x] + [x]^3 + 3[x]^5 \) then \( Df(x) = 1 + 3[2x^2] + 15[3x^4] \).

The fundamental theorem allows us to integrate and get the right values at the points \( k/n \):

8. Find \( Sf \) for the same function. The answer is \( Sf(x) = [x]^2/2 + [x]^4/4 + 3[3x^6]/6 \).

\[ \text{Define } \exp_h(x) = (1 + h)^{x/h}. \text{ It is equal to } 2^x \text{ for } h = 1 \text{ and morphs into the function } e^x \text{ when } h \text{ goes to zero. As a rescaled exponential, it is continuous and monotone.} \]

9. The function \( \exp_h(x) = (1 + h)^{x/h} \) satisfies \( D\exp_h(x) = \exp_h(x) \).

Solution: \( \exp_h(x + h) = (1 + h)^{x + h} \) shows that \( D\exp_h(x) = \exp_h(x) \).

10. Define \( \exp_{ah}(x) = (1 + ah)^{x/h} \). Now \( D\exp_{ah}(x) = a\exp_{ah}(x) \). Since \( \exp_{ah}(x) \) is not equal to \( \exp_{ah}(x) \), we write also \( \exp_{ah}(x) = \exp_{ah}(a \cdot x) \).

11. We can also replace \( a \) with the complex \( ai \) and consider \( \exp_{ai}(x) = (1 + aih)^{x/h} \). Now, \( D\exp_{ai}(x) = ai\exp_{ai}(x) \).

The real and imaginary parts define new functions \( \exp_{ai}(x) = \cos_{ai}(a \cdot x) + i \sin_{ai}(a \cdot x) \). We have \( D\sin_{ai}(a \cdot x) = a\cos_{ai}(a \cdot x) \) and \( D\cos_{ai}(a \cdot x) = -a\sin_{ai}(a \cdot x) \).

These functions morph into the familiar cos and sin functions for \( h \to 0 \). But in general, for any \( h \) and any \( a \), we have \( D\cos_{ai}(a \cdot x) = -a\sin_{ai}(a \cdot x) \) and \( D\sin_{ai}(a \cdot x) = a\cos_{ai}(a \cdot x) \).
Homework

We leave the $h$ away in this homework. To have more fun, also define $\log_h$ as the inverse of $\exp_h$ and define $1/|x|_h = D \log_h(x)$ for $x > 0$. If we start integrating from 1 instead of 0 as usual we have $S1/|x|_h = \log_h(x)$. 1 We also write here $x^n$ for $[x]_h^n$ and write $\exp(a \cdot x) = e^{ax}$ instead of $\exp(x)$ and $\log(x)$ instead of $\log_h(x)$ because we are among friends. Use the differentiation and integration rules on the right to find derivatives and integrals of the following functions:

1. Find the derivatives $Df(x)$ of the following functions:
   - a) $f(x) = x^2 + 6x^2 + x$
   - b) $f(x) = x^2 + \log(x)$
   - c) $f(x) = -3x^3 + 17x^2 - 5x$. What is $Df(0)$?

2. Find the integrals $Sf(x)$ of the following functions:
   - a) $f(x) = x^4$
   - b) $f(x) = x^2 + 6x^2 + x$
   - c) $f(x) = -3x^3 + 17x^2 - 5x$. What is $Sf(1)$?

3. Find the derivatives $Df(x)$ of the following functions:
   - a) $f(x) = \exp(3 \cdot x) + x^6$
   - b) $f(x) = 4 \exp(-3 \cdot x) + 9x^6$
   - c) $f(x) = -\exp(5 \cdot x) + x^6$

4. Find the integrals $Sf(x)$ of the following functions:
   - a) $f(x) = \exp(6 \cdot x) - 3x^6$
   - b) $f(x) = \exp(8 \cdot x) + x^6$
   - c) $f(x) = -\exp(5 \cdot x) + x^6$

5. Define $f(x) = \sin(4 \cdot x) - \exp(2 \cdot x) + x^3$ and assume $h = 1/100$ in part c.
   - a) Find $Df(x)$
   - b) Find $Sf(x)$
   - c) Determine the value of
     \[
     \frac{1}{100}[f(0) + f(1) + \cdots + f(99)] .
     \]

---

All calculus on 1/3 page

Fundamental theorem of Calculus:

$DSf(x) = f(x)$ and $Sf(x) = f(x) - f(0)$.

**Differentiation rules**

- $Dx^n = nx^{n-1}$
- $D\exp(a \cdot x) = ae^{ax}$
- $D\cos(a \cdot x) = -a \sin(a \cdot x)$
- $D\sin(a \cdot x) = a \cos(a \cdot x)$
- $D\log(x) = 1/x$

**Integration rules**

(for $x = kh$)

- $Sx^n = x^{n+1}/(n+1)$
- $Se^{ax} = (e^{ax} - 1)/a$
- $S\cos(a \cdot x) = \sin(a \cdot x)/a$
- $S\sin(a \cdot x) = -\cos(a \cdot x)/a$
- $S^{1/2} = \log(x)$

Fermat’s extreme value theorem: If $Df(x) = 0$ and $f$ is continuous, then $f$ has a local maximum or minimum in the open interval $(x, x + h)$.

---

Pictures

- $[x]_h^3$ for $h = 0.1$
- $\exp_h(x)$ for $h = 0.1$
- $\sin_h(x)$ for $h = 0.1$
- $\log_h(x)$ for $h = 0.1$

---

1 We do not see $h$ in daily lives, or do we? An allegory: in our universe, where $h = 1.616 \cdot 10^{-35}m$, the difference between the $\sin_h$ and $\sin$ is so small that a x-ray oscillating with $\nu = 10^{17}$ Hz traveling for 13 billion years $t = 4 \cdot 10^{17}s$ would only start to deviate noticeably from the classical $\sin(x)$ wave when it reaches us at $\nu \cdot t = 4 \cdot 10^{34}$ oscillations. Since $\sin_h(x) - \sin(x)$ only starts to grow at around $x = 1/h \sim 10^{35}$ oscillations, the x-ray would look the same when using the trig functions $\sin_h, \cos_h$. If $\gamma$ is in the Gamma ray spectrum $10^{19}Hz$, the functions $\sin_h, \cos_h$ start to grow in amplitude earlier. A $\gamma$ wave emitted 1 billion years ago would be observed as a Gamma ray burst.
Here are some worked out examples, similar to what we expect you to do for the homework of lecture 6: The homework should be straightforward, except when finding $Sf(x)$, we want to add a constant such that $Sf(0) = 0$. In general, you will not need to evaluate functions and can leave terms like $\sin(5 \cdot x)$ as they are. If you have seen calculus already, then you could do this exercise by writing

$$\frac{d}{dx} f(x)$$

instead of $Df(x)$ and by writing

$$\int_0^x f(x) \, dx$$

instead of $Sf(x)$. Since we did not introduce the derivative $\frac{df}{dx}$ nor the integral $\int f$ yet, for now, just use the differentiation and integrations rules in the box to the right to solve the problems.

1. **Problem:** Find the derivative $Df(x)$ of the function $f(x) = \sin(5 \cdot x) + x^7 + 3$.
   **Answer:** From the differentiation rules, we know $\frac{df}{dx} = 5 \cos(5 \cdot x) + 7x^6$.

2. **Problem:** Find the derivative $Df(0)$ of the same function $f(x) = \sin(5 \cdot x) + 5x^7 + 3$.
   **Answer:** We know $Df(x) = 5 \cos(5 \cdot x) + 35x^6$. Plugging in $x = 0$ gives 5.

3. **Problem:** Find the integral $Sf(x)$ of the function $f(x) = \sin(5 \cdot x) + 5x^7 + 3$.
   **Answer:** From the integration rules, we know $Sf(x) = -\cos(5 \cdot x)/5 + 5x^8/8 + 3$.

4. **Problem:** Find the integral $Sf(1)$ of the function $f(x) = x^2 + 1$.
   **Answer:** From the integration rules, we know $Sf(x) = x^3/3 + x$. Plugging in $x = 1$ gives $\frac{1}{3} + 1$ if we use the functions in the limit $h \to 0$. For positive $h$, we have to evaluate $x(x-h)(x-2h)/3 + x$ for $x = 1$ which is $(1-h)(1-2h)/3 + 1$

5. **Problem:** Find the integral $Sf(1)$ of the function $f(x) = \exp(4 \cdot x)$.
   **Answer:** From the integration rules, we know $Sf(x) = \exp(4 \cdot x)/4 - 1/4$. We have added a constant such that $Sf(0) = 0$. Plugging in $x = 1$ gives $\exp(4)/4 - 1/4$.

6. **Problem:** Assume $h = 1/1000$. Determine the value of

$$\frac{1}{1000}f\left(\frac{0}{1000}\right) + f\left(\frac{1}{1000}\right) + \ldots + f\left(\frac{999}{1000}\right)$$

for the function $f(x) = -\sin(7x) + \exp(3x)$.
   **Answer:** The problem asks for $Sf(1)$. We first compute $Sf(x)$ taking care that $Sf(0) = 0$.

$$Sf(x) = \cos(7x)/7 + \exp(3x)/3 - (1/7 + 1/3)$$

Now plug in $x = 1$ to get $\cos(7)/7 + \exp(3)/3 - (1/7 + 1/3)$. 

Lecture 6: Worksheet

The exponential function

We illuminate the fundamental theorem for the exponential function \( \exp(x) = (1+h)^{x/h} \). While the discussion could be done for any \( h > 0 \) we look at the special case where \( h = 1 \) in which case \( \exp(x) = 2^x \) maps positive integers to positive integers. You have verified in a homework that

\[
D \exp(x) = \exp(x) \, .
\]

From the fundamental theorem, we get \( SD \exp(x) = S \exp(x) = \exp(x) - \exp(0) \) for integers \( x \). That is

\[
S \exp(x) = \exp(x) - 1 \, .
\]

In other words, for the exponential function, we know both the derivative and the integral. \(^1\)

1. The formula \( S \exp(x) = \exp(x) - 1 \) tells for \( x = 5 \) that \( 1 + 2 + 4 + 8 + 16 = 32 - 1 \). Verify it for \( x = 7 \).

2. Because \( S \exp(x) = \exp(x) - 1 \) we can interpret \( \exp(x) - 1 \) as an area of a union of rectangles. In the picture below, shade an area \( \exp(3) - 1 \).

3. In the right of the two pictures, there is a line vertical segment which has length \( \exp(3) \). Which one?

4. We know \( D \exp(x) = \exp(x) \). Why is also the following formula true?

\[
D(\exp(x) - 1) = \exp(x)
\]

5. The just verified formula can be interpreted as a difference between areas and so an area. Which one for \( x = 4 \)?

\(^1\)Later in this course, we will look at these two formulas in the limit \( h \to 0 \), where

\[
\frac{d}{dx} \exp(x) = \exp(x), \quad \int_0^x \exp(t) \, dt = \exp(x) - 1.
\]
Lecture 7: Rate of change

Last week, we defined
\[ Df(x) = \frac{f(x + h) - f(x)}{h}. \]

It is the rate of change of the function with step size \( h \). When changing \( x \) to \( x + h \) and get a response change \( f(x) \) to \( f(x + h) \). In this lecture, we take the limit \( h \to 0 \) and derive the important formulas
\[ \frac{d}{dx} x^n = nx^{n-1}, \quad \frac{d}{dx} e^x = e^x, \quad \frac{d}{dx} \sin(x) = \cos(x), \quad \frac{d}{dx} \cos(x) = -\sin(x) \]
which we have seen already in a discrete setting.

1 You walk up a snow hill of height \( f(x) = 30 - x^2 \) meters. You walk with a step size of \( h = 0.5 \) meters. You are at position \( x = 3 \). How much do you climb or descend when making an other step? We have \( f(3) = 21 \) and \( f(3.5) = 17.75 \). We have walked down 3.25 meters. How steep was the snow hill at this point? We have to divide the height difference by the walking distance: \(-3.25/0.5 = -6.5\). Today, we take the limit \( h \to 0 \):

If the limit \( \frac{d}{dx} f(x) = \lim_{h \to 0} \frac{f(x + h) - f(x)}{h} \) exist, we say \( f \) is differentiable at the point \( x \). The value is called the derivative or instantaneous rate of change of the function \( f \) at \( x \). We denote the limit also with \( f'(x) \).

2 In the previous problem, \( f(x) = 30 - x^2 \) we have
\[ f(x + h) - f(x) = [30 - (x + h)^2] - [30 - x^2] = -2xh - h^2 \]
Dividing this by \( h \) gives \(-2x - h \). The limit \( h \to 0 \) gives \(-2x \). We have just seen that for \( f(x) = x^2 \), we get \( f'(x) = -2x \). For \( x = 3 \), this is \(-6 \). The actual slope of the snow hill is a bit smaller than the estimate done by walking. The reason is that the hill gets steeper.

The derivative \( f'(x) \) has a geometric meaning. It is the slope of the tangent at \( x \). This is an important geometric interpretation. It is useful to think about \( x \) as “time” and the derivative as the rate of change of the quantity \( f(x) \) in time.

For \( f(x) = x^n \), we have \( f'(x) = nx^{n-1} \).

Proof: \( f(x + h) - f(x) = (x + h)^n - x^n \). If we divide by \( h \), we get \( nx^{n-1}h + \ldots + h^n \). If we divide by \( h \), we get \( nx^{n-1} + h + \ldots + h^{n-1} \) for which the limit \( h \to 0 \) exists: it is \( nx^{n-1} \). This is an important result because most functions can be approximated very well with polynomials.

For \( f(x) = \sin(x) \) we have \( f'(0) = 1 \) because the differential quotient is \( f(0 + h) - f(0))/h = \sin(h)/h = \sin(h) \). We have already seen that the limit is 1 before.

Let’s look at it again geometrically. For all \( 0 < x < \pi/2 \) we have
\[ \sin(x) \leq x \leq \tan(x) \]
\[ \frac{\sin(x)}{x} \to 1 \] as \( x \to 0 \).

For \( f(x) = \cos(x) \) we have \( f'(x) = 0 \). To see this, look at \( f(0 + h) - f(0) = \cos(h) - 1 \). Geometrically, we can use Pythagoras \( \sin^2(h) + (1 - \cos(h))^2 = h^2 \) to see that \( \frac{2}{2} \cos(h) \leq h^2 \) or \( 1 - \cos(h) \leq h^2/2 \) so that \( (1 - \cos(h))/h \leq h/2 \) and this goes to 0 as \( h \to 0 \). We have just nailed down an other important identity
\[ \lim_{h \to 0} \frac{\sin(h)}{h} = 1 \]

The interpretation is that the tangent is horizontal for the cos function at \( x = 0 \). We will call this a critical point later on.

5 From the previous two examples, we get
\[ \cos(x + h) - \cos(x) = \cos(x) \cos(h) - \sin(x) \sin(h) = \cos(x)(\cos(h) - 1) - \sin(x) \sin(h) \]
because \( (\cos(h) - 1)/h \to 0 \) and \( \sin(h)/h \to 1 \), we see that \( \cos(x + h) - \cos(x) \)/h \to \( -\sin(x) \).

For \( f(x) = \cos(ax) \) we have \( f'(x) = -a \sin(ax) \).

6 Similarly,
\[ \sin(x + h) - \sin(x) = \cos(x) \sin(h) + \sin(x) \cos(h) - \sin(x) = \sin(x)(\cos(h) - 1) + \cos(x) \sin(h) \]
because \( (\cos(h) - 1)/h \to 0 \) and \( \sin(h)/h \to 1 \), we see that \( \sin(x + h) - \sin(x) \)/h \to \( \cos(x) \).

For \( f(x) = \sin(ax) \), we have \( f'(x) = a \cos(ax) \).
Like $\pi$, the Euler number $e$ is irrational. Here are the first digits: 2.7182818284590452354.

If you want to find an approximation, just pick a large $n$, like $n = 100$ and compute $(1 + 1/n)^n$. For $n = 100$ for example, we see $101^{100}/100^{100}$. We only need $101^{100}$ and then put a comma after the first digit to get an approximation. Interested why the limit exists? Verify that the fractions $A_n = (1 + 1/n)^n$ increase and $B_n = (1 + 1/n)^{n+1}$ decrease. Since $B_n/A_n = (1 + 1/n) = (1 + 1/n)^{n+1}$ which goes to $1$ for $n \to \infty$, the limit exists. The same argument shows that $(1 + 1/n)^n = \exp(x)$ increases and $\exp(x)(1 + 1/n)$ decreases. The limiting function $\exp(x) = e^x$ is called the exponential function. Remember that if we write $h = 1/n$, then $(1 + 1/n)^n = \exp(h)$ considered earlier in the course. We can sandwich the exponential function between \(\exp_h(x)\) and $(1 + h)\exp_h(x)$:

\[
\exp_h(x) \leq \exp(x) \leq \exp_h(x)(1 + h), \quad x \geq 0.
\]

For $x < 0$, the inequalities are reversed.

Let us compute the derivative of $f(x) = e^x$ at $x = 0$. Answer. We have

\[
((1 + 1/n)^n - 1)n \leq (e^h - 1)/h \leq ((1 + 1/n)^{n+1} - 1)n
\]

Use the binomial formula to see that both the left and right hand side go to 1 if $n \to \infty$. Therefore $f'(0) = 1$. The exponential function has a graph which has slope 1 at $x = 0$.

Now, we can get the general case. It follows from $e^{x+h} - e^x = e^x(e^h - 1)$ that the derivative of $\exp(x)$ is $\exp(x)$.

For $f(x) = \exp(ax)$, we have $f'(ax) = a\exp(ax)$. It follows from the properties of taking limits that $(f(x) + g(x))' = f'(x) + g'(x)$. We also have $(af(x))' = af'(x)$. From this, we can now compute many derivatives.

Find the slope of the tangent of $f(x) = \sin(3x) + 5\cos(10x) + e^{5x}$ at the point $x = 0$. Solution: $f'(x) = 3\cos(3x) - 50\sin(10x) + 5e^{5x}$. Now evaluate it at $x = 0$ which is $3 + 0 + 5 = 8$.

Finally, let’s mention an example of a function which is not everywhere differentiable.

The function $f(x) = |x|$ has the properties that $f'(x) = 1$ for $x > 0$ and $f'(x) = -1$ for $x < 0$. The derivative does not exist at $x = 0$ even so the function is continuous there. You see that the slope of the graph jumps discontinuously at the point $x = 0$.

For a function which is discontinuous at some point, we don’t even attempt to differentiate it there. For example, we would not even try to differentiate $\sin(1/x)$ at $x = 0$ nor $f(x) = 1/x^4$ at $x = 0$ or $\sin(x)/|x|$ at $x = 0$. Remember these bad guys?

To the end, you might have noticed that in the boxes, more general results have appeared, where $x$ is replaced by $ax$. We will look at this again but in general, the relation $f'(ax) = a f(ax)$ holds (“if you drive twice as fast, you climb twice as fast”).

**Homework**

1. For which of the following functions does the derivative exist for all points?
   a) $|\sin(x)|$
   b) $|\exp(x)|$
   c) $\exp(x) + \sin(15x)$
   d) $\cos(x)$
   e) $\sin(1/x)$
   f) $|\exp(x)| + |1 + \sin(15x)|$

2. a) A circle of radius $x$ has the area $f(r) = \pi r^2$. Find $\frac{df}{dr}(r)$. Can you visualize why this is the same than the circumference of the circle.
   b) The sphere of radius $r$ has the volume $f(r) = 4\pi r^3/3$. Find $\frac{df}{dr}(r)$ and compare it with the surface area of the sphere.
   c) A hypersphere of radius $r$ has the hyper volume $f(r) = \pi^2 r^4/2$. Find $\frac{df}{dr}(r)$, the volume of the boundary sphere.

3. Find the derivatives of the following functions at the point $x = 2$.
   a) $f(x) = \exp(x) + \sin(x) + x^2 + x^4 + x^5$
   b) $f(x) = (x^2 - 1)/(x - 1) + \cos(2x)$
   c) $f(x) = \frac{4x^4 + x^2 + 3x^2 + 4x^4 + x^2 + x^5}{x^2 + 5x + 1}$

4. In this problem we compute the derivative of $\sqrt{x}$ for $x > 0$. To do so, we have to find the limit

   \[ \lim_{h \to 0} \frac{\sqrt{x + h} - \sqrt{x}}{h} \]

   Hint: multiply the top and the bottom with $(\sqrt{x + h} + \sqrt{x})$ and simplify.

5. A rocket lifts off from Cape Canaveral. The height at time $t$ is $h(t) = e^t - 1 + \sqrt{t}$, at least for the first few seconds. Find the rate of change of the height at time $t = 1$. Use the previous problem to get the derivative of $\sqrt{t}$. 
Lecture 7: Worksheet

Rate of change

We compute the derivative of \( f(x) = 1/x \) by taking limits.

a) Simplify \( \frac{1}{x+h} - \frac{1}{x} \).
b) Now take the limit \( \frac{1}{h} \left[ \frac{1}{x+h} - \frac{1}{x} \right] \) when \( h \to 0 \).
c) Is there any point where \( f'(x) > 0 \)?

Derivatives

Differentiation rules

\[
\frac{d}{dx} x^n = nx^{n-1} \\
\frac{d}{dx} e^{ax} = ae^{ax} \\
\frac{d}{dx} \cos(ax) = -a \sin(ax) \\
\frac{d}{dx} \sin(ax) = a \cos(ax)
\]

1. Find the derivatives of the function \( f(x) = \sin(3x) + x^5 \)
2. Find the derivative of \( f(x) = \cos(7x) - 8x^4 \).
3. Find the derivative of \( f(x) = e^{5x} + \cos(2x) \).
Lecture 8: The derivative function

In the last lecture, we have introduced the derivative \( f'(x) = \frac{d}{dx} f(x) \) as a limit of \( Df(x) \) for \( h \to 0 \). We have seen that \( \frac{d}{dx} x^n = nx^{n-1} \) holds for integer \( n \). We also know already that \( \sin' = \cos, \cos' = -\sin \) and \( \exp' = \exp \). We can already differentiate a lot of functions and evaluate the derivative \( f'(x) \) at some point \( x \). This is the slope of the curve at \( x \).

1. Find the derivative \( f'(x) \) of \( f(x) = \sin(\pi x) + \cos(\pi x) - \sqrt{x} + \frac{1}{x} + x^4 \) and evaluate it at \( x = 1 \).

   Solution: \( f'(x) = \pi \cos(\pi x) - \pi \sin(\pi x) - 1/(2\sqrt{x} - 1/x^2 + 4x^3) \). Plugging in \( x = 1 \) gives \(-\pi - 1/2 - 1 + 4\).

Taking the derivative at every point defines a new function, the derivative function. For example, for \( f(x) = \sin(x) \), we get \( f'(x) = \cos(x) \). In this lecture, we want to understand the new function and its relation with \( f \). What does it mean if \( f'(x) > 0 \)? What does it mean that \( f'(x) < 0 \)? Do the roots of \( f \) tell something about \( f' \) or do the roots of \( f' \) tell something about \( f \)?

Here is an example of a function and its derivative. Can you see the relation?

Here is an interesting inverse problem called bottle calibration problem. We fill a circular bottle or glass with constant amount of fluid. Plot the height of the fluid in the bottle at time \( t \). Assume the radius of the bottle is \( f(z) \) at height \( z \). Can you find a formula for the height \( g(t) \) of the water? This is not so easy. But we can find the rate of change \( g'(t) \). Assume for example that \( f \) is constant, then the rate of change is constant and the height of the water increases linearly like \( g(t) = t \). If the bottle gets wider, then the height of the water increases slower. There is definitely a relation between the rate of change of \( g \) and \( f \).

Before we look at this more closely, lets try to match the following cases of bottles with the graphs of the functions \( g \) qualitatively.

2. In each of the bottles, we call \( g \) the height of the water level at time \( t \), when filling the bottle with a constant stream of water. Can you match each bottle with the right height function?

To understand the relation, it is good to distinguish intervals, where \( f(x) \) is increasing or decreasing. This are the intervals where \( f'(x) \) is positive or negative.

A function is called **monotonically increasing** on an interval \( I = (a, b) \) if \( f'(x) > 0 \) for all \( x \in (a, b) \). It is **monotonically decreasing** if \( f'(x) < 0 \) for all \( x \in (a, b) \).

Let's look at the previous example again.

The key is to look at \( g'(t) \), the rate of change of the height function. Because \( [g(t+h) - g(t)]/h \) times the area \( \pi f^2 \) is a constant times the time difference \( h = dt \), we have

\[ g' = \frac{1}{\pi f^2}. \]
This formula relates the derivative function of \( g \) with the thickness \( f(t) \) of the bottle at height \( g \). It tells that if \( f \) is large, then \( g' \) is small and if \( f \) is small, then \( g' \) is large. Finding \( g \) from \( f \) is possible but we are not doing this now.

3 Can you find a function \( f \) which is bounded \( |f(x)| \leq 1 \) and such that \( f'(x) \) is unbounded?

Given the function \( f(x) \), we can define \( g(x) = f'(x) \) and then take the derivative \( g' \) of \( g \). This second derivative \( f''(x) \) is called the acceleration. It measures the rate of change of the tangent slope. For \( f(x) = x^4 \), for example we have \( f''(x) = 12x^2 \). If \( f''(x) > 0 \) on some interval the function is called concave up, if \( f''(x) < 0 \), it is concave down.

Given the function \( f(x) \), we can define \( g(x) = f'(x) \) and then take the derivative \( g' \) of \( g \). This second derivative \( f''(x) \) is called the acceleration. It measures the rate of change of the tangent slope. For \( f(x) = x^4 \), for example we have \( f''(x) = 12x^2 \). If \( f''(x) > 0 \) on some interval the function is called concave up, if \( f''(x) < 0 \), it is concave down.

4 Find a function \( f \) which has the property that its acceleration is constant equal to 10.

5 Can you find a function \( f \) which is bounded \( |f(x)| \leq 1 \) and such that \( f''(x) \) is positive everywhere?

### Homework

1 For the following functions, determine on which intervals the function is monotonically increasing or decreasing.
   a) \( f(x) = x^3 - x \).
   b) \( f(x) = \sin(\pi x) \).
   c) \( f(x) = e^{2x} - 2e^x \).

2 Match the following functions with their derivatives. Give short explanations for each match.

3 Match also the following functions with their derivatives. Give short explanations documenting your reasoning in each case.

4 Draw for the following functions the graph of the function \( f(x) \) as well as the graph of its derivative \( f'(x) \). You do not have to compute the derivative analytically as a formula here since we do not have all tools yet to compute the derivatives. The derivative function you draw needs to have the right qualitative shape however.
   a) The Gaussian bell curve or the "To whom the bell tolls" function
      \[ f(x) = e^{-x^2} \]
   b) The witch of Maria Agnesi.
      \[ f(x) = \frac{1}{1 + x^2} \]
   c) The three gorges function
      \[ f(x) = \frac{1}{x} + \frac{1}{x-1} + \frac{1}{x+1} \].

5 Below you the graphs of three derivative functions \( f'(x) \). In each case you are told that \( f(0) = 1 \). Your task is to draw the function \( f(x) \) in each of the cases a), b), c). Your picture does not have to be up to scale, but your drawing should display the right features.
Match the following functions with their derivatives and then with the derivatives of the derivatives.

In this worksheet we want to match the graphs of functions with their derivatives and second derivatives. This is tougher than you might think. Here is an example:

The first graph shows the function, which is here the quadratic function. The slope on the right hand side is positive and increasing, on the left hand side the function is negative and decreasing. The middle graph shows the derivative function which is linear. The final graph shows the derivative function of the derivative function. It is constant in this case.
Lecture 9: The product rule

In this lecture, we look at the derivative of a product of functions. The product rule is also called the Leibniz rule, named after Gottfried Leibniz, who found it in 1684. It is a very important rule because it allows us to differentiate many more functions. If we wanted to compute the derivative of \( f(x) = x \sin(x) \) for example, we would have to get under the hood of the function and compute the limit \( \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} \). We are too lazy for that. Let’s start with the identity

\[
f(x+h)g(x+h) - f(x)g(x) = [f(x+h) - f(x)] \cdot g(x+h) + f(x) \cdot [g(x+h) - g(x)]
\]

which can be written as \( D(fg) = Df \cdot g + f \cdot Dg \) with \( Dg(x) = g(x+h) - g(x) \). This quantum Leibniz rule can also be seen geometrically: the rectangle of area \((f + df)(g + dg)\) is the union of rectangles with area \(f \cdot g, f \cdot dg\) and \(df \cdot g\). Divide this relation by \( h \) to see

\[
\frac{[f(x+h) - f(x)] \cdot g(x+h)}{h} \to f'(x) \cdot g(x)
\]

\[
\frac{f(x) \cdot [g(x+h) - g(x)]}{h} \to f(x) \cdot g'(x)
\]

We get the extraordinarily important product rule:

\[
\frac{d}{dx}(f(x)g(x)) = f'(x)g(x) + f(x)g'(x)
\]

1. Find the derivative function \( f' \) for \( f(x) = x^3 \sin(x) \). Solution: We know how to differentiate \( x^3 \) and \( \sin(x) \) so that \( f'(x) = 3x^2 \sin(x) + x^3 \cos(x) \).

2. While we know \( \frac{d}{dx} x^5 = 5x^4 \) lets compute this with the Leibniz rule and write \( x^5 = x^3 \cdot x^2 \). We have \( \frac{d}{dx} x^3 = 3x^2, \frac{d}{dx} x^2 = 2x \).

The Leibniz rule gives us \( \frac{d}{dx} x^5 = 3x^4 \cdot 2x + 2x^4 = 5x^4 \).

Water powered JetLev systems have now gone into production. The water is sucked up from the water surface from a four-inch diameter polyester hose. Consider a system, where the water is carried with you. By Newton’s law the force \( F \) satisfies \( F = p' \), where \( p = mv \) is the momentum, the product of your mass and velocity. Written out, this is

\[
F(t) = \frac{d}{dt}(mv(t)v(t))
\]

How big is the acceleration \( v' \)? The product rule tells us \( F = m'v + mv' \) which gives \( v' = (F - m'v)/m \). Since we throw out water, \( m'(t) \) is negative and \( m(t) \) decreases, we accelerate if the force \( F \) is kept constant.

The Leibniz rule is also called the product rule. It suggests a quotient rule. One can avoid the quotient rule by writing it as a product \( f(x)/g(x) = f(x) \cdot 1/g(x) \) and by using the reciprocal rule:

\[
\text{If } g(x) \neq 0, \text{ then } \frac{d}{dx} \left( \frac{1}{g(x)} \right) = \frac{-g'(x)}{g(x)^2}.
\]

To verify it, stare at the identity

\[
\frac{1}{g(x+h)} - \frac{1}{g(x)} = \frac{g(x) - g(x+h)}{g(x)(g(x+h))}.
\]

Dividing it by \( h \) gives \( D(1/g(x)) = -D(g(x))/g(x)g'(x) \). Taking the limit \( h \to 0 \) leads to the identity. An other way to derive this is to write \( h = 1/g \) and differentiate \( 1 = gh \) on both sides. The product rule gives \( 0 = g'h + gh' \) so that \( h' = -g'h/g = -g'g^2 \).

4. Find the derivative of \( f(x) = 1/x^4 \). Solution: \( f'(x) = -4x^3/x^8 = -4/x^5 \). The same computation shows that \( \frac{d}{dx} x^n = nx^{n-1} \) holds for all integers \( n \).

The formula \( \frac{d}{dx} x^n = nx^{n-1} \) holds for all integers \( n \).

The quotient rule is obtained by applying the product rule to \( f(x) \cdot (1/g(x)) \) and using the reciprocal rule:

\[
\text{If } g(x) \neq 0, \text{ then } \frac{d}{dx} \left( \frac{f(x)}{g(x)} \right) = \frac{f'(x)g(x) - f(x)g'(x)}{g^2(x)}.
\]
5. Find the derivative of \( f(x) = \tan(x) \). **Solution:** because \( \tan(x) = \sin(x)/\cos(x) \) we have 
\[
\tan'(x) = \frac{\sin^2(x) + \cos^2(x)}{\cos^2(x)} = \frac{1}{\cos^2(x)}.
\]

6. Find the derivative of \( f(x) = \frac{\sqrt{x^3 + 1}}{x^2 + 1} \). **Solution:** We apply the quotient rule and get 
\[
\frac{((x^3 + 1))(2x^2) - ((x^2 + 1))(3x^2)}{(x^2 + 1)^2} = \frac{-x^2}{x^2 + 1}.
\]

7. Find the second derivative of \( \tan(x) \). **Solution:** We have already computed \( \tan'(x) = 1/\cos^2(x) \). Differentiate this again with the quotient rule gives 
\[
\frac{\sec^2(x) \cdot \cos^2(x) - 2 \sec^2(x) \cdot \cos(x) \cdot \sin(x)}{\cos^4(x)} = \frac{\sec^2(x)}{\cos^2(x)}.
\]

8. A cylinder has volume \( V = \pi r^2 h \), where \( r \) is the radius and \( h \) is the height. Assume the radius grows like \( r(t) = 1 + t \) and the height shrinks like \( 1 - \sin(t) \). Does the volume grow or decrease at \( t = 0 \)? **Solution:** The volume \( V(t) = \pi (1 + t)^2 (1 - \sin(t)) \) is a product of two functions \( f(t) = \pi (1 + t)^2 \) and \( g(t) = 1 - \sin(t) \). We have \( f(0) = 1 \), \( g(0) = 2 \), \( f'(0) = 2 \), \( g(0) = 1 \). The product rule gives \( V'(0) = \pi 1 \cdot (-1) + 2 \cdot 1 = \pi \). The volume increases in volume at first.

9. On the **Moscow papyrus** dating back to 1850 BC, the general formula \( V = h(a^2 + ab + b^2)/3 \) for a truncated pyramid with base length \( a \), roof length \( b \) and height \( h \) appeared. Assume \( h(t) = 1 + \sin(t) \), \( a(t) = 1 + t \), \( b(t) = 1 - 2t \). Does the volume of the truncated pyramid grow or decrease at first? **Solution:** We could fill in \( a(t), b(t), h(t) \) into the formula for \( V \) and compute the derivative using the product rule. A bit faster is to write \( f(t) = a^2 + ab + b^2 = (1+t)^2(1-3t)^2 + (1+2t)(1-3t) \) and note \( f(0) = 3 \), \( f'(0) = -6 \) then get from \( h(t) = (1+\sin(t)) \) the data \( h(0) = 1 \), \( h'(0) = 0 \). So that \( V'(0) = (h'(0)f(0) - h(0)f'(0))/3 = (1-3-(-6))/3 = -1 \). The pyramid shrinks in volume at first.

10. We pump up a balloon and let it fly. Assume that the thrust increases like \( t \) and the resistance decreases like \( 1/\sqrt{1-t} \) since the balloon gets smaller. The distance traveled is \( f(t) = t/\sqrt{1-t} \). Find the velocity \( f'(t) \) at time \( t = 0 \).

---

**Homework**

1. Find the derivatives of the following functions:
   a) \( f(x) = \sin(3x) \cos(10x) \).
   b) \( f(x) = \sin^2(x)/x^2 \).
   c) \( f(x) = x^4 \sin(x) \cos(x) \).
   d) \( f(x) = 1/\sqrt{x} \).
   e) \( f(x) = \cot(x) + (1 + x)/(1 + x^2) \).

2. a) Verify that for \( f(x) = g(x)h(x)k(x) \) the formula \( f' = g'hk + gh'k + ghk' \) holds.
   b) Verify the following formula for derivative of \( f(x) = g(x)^3 \): \( f'(x) = 3g^2(x)g'(x) \).

3. a) If \( f(x) = \sin(x)/x \), find its derivative \( g(x) = f'(x) \) and then the derivative of \( g(x) \). Then evaluate it at \( x = 0 \).
   b) If you evaluate \( g(x) \) at \( x = 0 \) you obtain \( g(0) = f'(0) = 0 \). Is the result in a) not a contradiction to the fact that for \( g = 0 \) the derivative \( g' \) is 0?

4. Find the derivative of
   \[
   \frac{\sin(x)}{1 + \cos(x) + \frac{x^2}{\sec(x)}}
   \]
   at \( x = 0 \).

5. a) Verify that in general the derivative of \( g(x) = f(x)^2 \) is \( 2f(x)f'(x) \).
   b) We have already computed the derivative of \( f(x) = \sqrt{x} \) in the last homework by directly computing the limit. Let’s do it using the product rule. Use part a) of this problem to compute the derivative of \( g(x) = f(x) \cdot f(x) \).
   c) Use the obtained identity \( g'(x) = \ldots \) to get a formula for \( f'(x) = \frac{1}{\sqrt{g(x)}} \).

Lecture 9: Worksheet

The product rule

We practice the product, reciprocal and quotient rule

1. Find the derivative of the sinc-function \( \frac{\sin(x)}{x} \) at the point \( x = 0 \).

2. What is the slope of the graph of the function \( f(x) = xe^{-x^2} \) at \( x = 0 \)?

3. Find the derivative of \( \sqrt{x}/x \) at \( x = 1 \). (Look first!)

4. Find the derivative of \( 1/e^x \) at \( x = 1 \). (Look first!)

5. Assume we remember the formula \( \sin(2x) = 2\sin(x)\cos(x) \). Differentiate both sides to get a formula for \( \cos(2x) \).

6. Find the derivative of \( x - 1/(x^2 + 1) \) at \( x = 0 \).

Source: XKCD

Leibniz 1684 paper. The product and quotient rule is introduced.
Lecture 10: The chain rule

In this lecture, we look at the derivative of a composition of functions. Also this rule is important. It will allow us to compute derivatives like for $f(x) = \sin(x^3)$ which is a composition of two functions $f(x) = x^3$ and $g(x) = \sin(x)$. We can in this example not use the product rule since we do not have a product of functions. It is a composition of functions. How do we compute the derivative functions which are “chained” together like this? The answer to this question is given by the chain rule:

$$\frac{df}{dx} = f'(g(x))g'(x).$$

The chain rule follows from the identity

$$\frac{f(g(x+h)) - f(g(x))}{h} = \frac{[f(g(x) + (g(x+h) - g(x))) - f(g(x))]}{[g(x+h) - g(x)]} \cdot \frac{g(x+h) - g(x)}{h}.$$

Write $H(x) = g(x+h)-g(x)$ in the first part on the right hand side

$$\frac{f(g(x+h)) - f(g(x))}{h} = \frac{[f(g(x) + H) - f(g(x))]}{H} \cdot \frac{g(x+h) - g(x)}{h}.$$

As $h \to 0$, we also have $H \to 0$ and the first part goes to $f'(g(x))$ and the second factor has $g'(x)$ as a limit.

1. Find the derivative of $f(x) = (4x - 1)^7$. **Solution** The inner function is $4x - 1$ which has the derivative $4$. We get therefore $f'(x) = 17(4x - 1)^6 \cdot 4 = 68(4x - 1)^6$. Remark. We could have expanded out the power $(4x - 1)^7$ first and avoided the chain rule. Avoiding the chain rule is called the **pain rule**.

2. Find the derivative of $f(x) = \sin(\pi \cos(x))$ at $x = 0$. **Solution**: applying the chain rule gives $\cos(\pi \cos(x)) \cdot (-\pi \sin(x))$.

3. For linear functions $f(x) = ax + b$, $g(x) = cx + d$, the chain rule can readily be checked. We have $f(g(x)) = a(cx + d) + b = acx + ad + b$ which has the derivative $ac$. Indeed this is the definition of $f$ times the derivative of $g$. You can convince you that the chain rule is true also from this example since if you look closely at a point, then the function is close to linear.

One of the cool applications of the chain rule is that we can compute derivatives of inverse functions:

4. Find the derivative of the natural logarithm function $\log(x)$ \footnote{We always write $\log(x)$ for the natural log. The $\ln$ notation is old fashioned and only used in obscure places like calculus books and calculators from the last millenium.} **Solution** Differentiate the identity $\exp(\log(x)) = x$. On the right hand side we have $1$. On the left hand side the chain rule gives $\exp(\log(x)) \log'(x) = x \log'(x) = 1$. Therefore $\log'(x) = 1/x$.

Denote by $\arccos(x)$ the inverse of $\cos(x)$ on $[0, \pi]$ and with $\arcsin(x)$ the inverse of $\sin(x)$ on $[-\pi/2, \pi/2]$.

5. Find the derivative of $\arcsin(x)$. **Solution** We write $x = \sin(\arcsin(x))$ and differentiate.

$$\frac{d}{dx} \arcsin(x) = \frac{1}{\sqrt{1-x^2}}.$$

6. Find the derivative of $\arccos(x)$. **Solution** We write $x = \cos(\arccos(x))$ and differentiate.

$$\frac{d}{dx} \arccos(x) = -\frac{1}{\sqrt{1-x^2}}.$$

7. $f(x) = \sin(x^2 + 3)$. Then $f'(x) = \cos(x^2 + 3)2x$.

8. $f(x) = \sin(\sin(x))$. Then $f'(x) = \cos(\sin(x))\cos(x)$.

Why is the chain rule called ”chain rule”\footnote{We always write $\log(x)$ for the natural log. The $\ln$ notation is old fashioned and only used in obscure places like calculus books and calculators from the last millenium.}? The reason is that we can chain even more functions together.

9. Let’s compute the derivative of $\sin(\sqrt{x^2-1})$ for example. **Solution**: This is a composition of three functions $f(g(h(x)))$, where $h(x) = x^2-1$, $g(x) = \sqrt{x}$ and $f(x) = \sin(x)$. The chain rule applied to the function $\sin(x)$ and $\sqrt{x^2-1}$ gives $\sin(\sqrt{x^2-1})\frac{1}{2}\sqrt{x^2-1}$. Apply now the chain rule again for the derivative on the right hand side.

Here is the famous **falling ladder problem**. A stick of length 1 slides down a wall. How fast does it hit the floor if it slides horizontally on the floor with constant speed? The ladder connects the point $(0, y)$ on the wall with $(x, 0)$ on the floor. We want to express $y$ as a function of $x$. We have $y = f(x) = \sqrt{1-x^2}$. Taking the derivative, assuming $x' = 1$ gives $f'(x) = -2x\sqrt{1-x^2}$.

10. In reality, the ladder breaks away from the wall. One can calculate the force of the ladder to the wall. The force becomes zero at the **break-away angle** $\theta = \arcsin(2(2\pi^2/3g))^{2/3}$, where $g$ is the gravitational acceleration and $v = x'$ is the velocity.

11. For the brave: find the derivative of $f(x) = \cos(\cos(\cos(\cos(x))))$.
## Homework

1. Find the derivatives of the following functions
   a) \( f(x) = \cos(\sqrt{x}) \)
   b) \( f(x) = \tan(1/x^2) \)
   c) \( f(x) = \exp(1/(1 + x)) \)
   d) \( (2 + \sin(x))^{-5} \)

2. Find the derivatives of the following functions at \( x = 1 \). (Problems c,d) were cut off on the originally distributed pset and are not required. Do them nevertheless to have more practice).
   a) \( f(x) = x^4 \log(x) \)
   b) \( \sqrt{x^5 + 1} \)
   c) \( (1 + x^2 + x^4)^{100} \)
   d) \( x^{\sqrt{x}} \)

3. a) Find the derivative of \( f(x) = 1/x \) by differentiating the identity \( x f(x) = 1 \).
   b) Find the derivative of \( f(x) = \arccot(x) \) by differentiating \( \cot(\arccot(x)) = x \).

4. a) Find the derivative of \( f(x) = \sqrt{x} \) by differentiating the identity \( f(x)^2 = x \).
   b) Find the derivative of \( f(x) = x^{m/n} \) by differentiating the identity \( f(x)^n = x^m \).

The function \( f(x) = [\exp(x) + \exp(-x)]/2 \) is called \( \cosh(x) \).

The function \( f(x) = [\exp(x) - \exp(-x)]/2 \) is called \( \sinh(x) \).

They are called **hyperbolic cosine** and **hyperbolic sine**. The first is even, the second is odd. You can see directly using \( \exp'(x) = \exp(x) \) and \( \exp'(-x) = -\exp(-x) \) that \( \sinh'(x) = \cosh(x) \) and \( \cosh'(x) = \sinh(x) \). Furthermore \( \exp = \cosh + \sinh \) writes \( \exp \) as a sum of an even and odd function.

5. a) Find the derivative of the inverse \( \text{arccosh}(x) \) of \( \cosh(x) \).
   b) Find the derivative of the inverse \( \text{arsinh}(x) \) of \( \sinh(x) \).

Apropos chain: if you look at the shape of a chain hanging at two points, then it is in the shape of the hyperbolic cosine.
The chain rule

On this valentine day, we preview a nice application of the chain rule. We will cover this later in the course.

The Valentine equation $(x^2 + y^2 - 1)^3 - x^2 y^3 = 0$ relates $x$ with $y$, but we can not write the curve as a graph of a function $y = g(x)$. Extracting $y$ or $x$ is difficult since they are in love. The set of points satisfying the equation looks like a heart. Well, romance is known to be complicated!

You can check that $(1, 1)$ satisfies the Valentine equation. Near it, the curve looks like the graph of a function $g(x)$. Let’s fill that in and look at the function

$$f(x) = (x^2 + g(x)^2 - 1)^3 - x^2 g(x)^3$$

The key is that $f(x)$ is actually zero and if we take the derivative, then we get zero too. Using the chain rule, we can take the derivative

$$f'(x) = 3(x^2 + g(x)^2 - 1)(2x + 2x g(x) g'(x)) - 2x g(x)^3 - x^2 3 g(x)^2 g'(x) = 0$$

Magically, we can solve for $g'$

$$g'(x) = \frac{3(x^2 + g(x)^2 - 1)2x - 2x g(x)^3}{3(x^2 + g(x)^2 - 1)2g(x) - 3x^2 g(x)^2}.$$  

Filling in $x = 1, g(x) = 1$, we see this is $-4/3$. We have computed the slope of $g$ without knowing $g$. Isn’t that magic? If this was a bit too complicated, don’t worry. We will have an entire lecture on this later in the course.

1. Compute the derivative of $f(x)$ using the chain rule and verify the formula above.
Lecture 11: Local extrema

Maximizing and minimizing functions is an important task. The reasons are obvious: we want to maximize nice quantities and minimize unpleasant ones. Extremizing quantities is also the most important principle nature follows. Important laws in physics like Newton’s law, equations describing light, or matter can be based on the principle of extremization. The intuition is that at maxima or minima the tangent to the graph is horizontal. This leads to a zero derivative and the notion of critical points:

A point \( x_0 \) is a critical point of a differentiable function \( f \) if \( f'(x_0) = 0 \).

In some textbooks, critical points include points where \( f' \) is not defined. In this course we do not include these points in the list of critical points. They are points outside the domain of definition of \( f' \) and will be treated separately.

Find the critical points of the function \( f(x) = x^3 + 3x^2 - 24x \). Solution: we compute the derivative as \( f'(x) = 3x^2 + 6x - 24 \). The roots of \( f' \) are 2, -4.

A point is called a local maximum of \( f \), if there exists a neighborhood \( U = (p - \alpha, p + \alpha) \) of \( p \), such that \( f(p) \geq f(x) \) for all \( x \in U \). Similarly, we define a local minimum. Local maxima and minima together are called local extrema.

The point \( x = 0 \) is a local maximum for \( f(x) = \cos(x) \). The reason is that \( f(0) = 1 \) and \( f(x) \) is decreasing for \( 0 < x < 1 \) nearby.

The point \( x = 1 \) is a local minimum for \( f(x) = (x - 1)^2 \). The function is zero at \( x = 1 \) and positive everywhere else.

Fermat: If \( f \) is differentiable and has a local extremum at \( x \), then \( f'(x) = 0 \).

Why? Assume the derivative \( f'(x) = c \) is not zero. We can assume \( c > 0 \) otherwise replace \( f \) with \(-f\). By the definition of limits, for some large enough \( h \), we have \( f(x + h) - f(x)/h \geq c/2 \). But this means \( f(x + h) \geq f(x) + hc/2 \) and \( x \) can not be a local maximum. Since also \( (f(x) - f(x - h))/h \geq c/2 \) for small enough \( h \), we also have \( f(x - h) \leq f(x) - hc/2 \) and \( x \) can not be a local minimum.

The derivative of \( f(x) = 72x - 30x^2 - 8x^3 + 3x^4 \) is \( f'(x) = 72 - 60x - 24x^2 + 12x^3 \). By plugging in integers (calculus teachers like integer roots because students like integer roots!) we can guess the roots \( x = 1, x = 3, x = -2 \) and see \( f'(x) = 12(x - 1)(x + 2)(x - 3) \). The critical points are 1, 3, -2.

We have already seen that \( f'(x) = 0 \) does not assure that \( x \) is a local extremum. The function \( f(x) = x^3 \) is a counter example. It satisfies \( f'(0) = 0 \) but 0 is not a local extremum. It is an example of an inflection point, a point where \( f'' \) changes sign.

Let’s look at one nasty example. The function \( f(x) = x \sin(1/x) \) is continuous at 0 but there are infinitely many critical points near 0.

If \( f''(x) > 0 \), then the graph of the function is concave up. If \( f''(x) < 0 \) then the graph of the function is concave down.

Second derivative test. If \( x \) is a critical point of \( f \) and \( f''(x) > 0 \), then \( f \) is a local minimum. If \( f''(x) < 0 \), then \( f \) is a local maximum.

If \( f''(x_0) > 0 \) then \( f'(x) \) is negative for \( x < x_0 \) and positive for \( x > x_0 \). This means that the function decreases left from the critical point and increases right from the critical point. Similarly, if \( f''(x_0) < 0 \) then \( f'(x) \) is positive for \( x < x_0 \) and \( f'(x) \) is positive for \( x > x_0 \). This means that the function increases left from the critical point and increases right from the critical point.

The function \( f(x) = x^2 \) has one critical point at \( x = 0 \). Its second derivative is 2 there.

Find the local maxima and minima of the function \( f(x) = x^3 - 3x \) using the second derivative test. Solution: \( f''(x) = 3x^2 - 3 \) has the roots 1, -1. The second derivative \( f''(x) = 6x \) is negative at \( x = -1 \) and positive at \( x = 1 \). The point \( x = -1 \) is therefore a local maximum and the point \( x = 1 \) is a local minimum.

Find the local maxima and minima of the function \( f(x) = \cos(\pi x) \) using the second derivative test.

For the function \( f(x) = x^5 - x^3 \), the second derivative test is inconclusive at \( x = 0 \). Can you nevertheless see the critical points?
Also for the function $f(x) = x^4$, the second derivative test is inconclusive at $x = 0$. The second derivative is zero. Can you nevertheless see whether the critical point 0 is local maximum or local minimum?

Finally, let's look at an example, where we can practice a bit the chain rule.

Find the critical points of $f(x) = 4 \arctan(x) + x^2$. Solution. The derivative is

$$f'(x) = \frac{4}{1 + x^2} + 2x = \frac{2x + 2x^3 + 4}{1 + x^2}.$$ 

We see that $x = -1$ is a critical point. There are no other roots of $2x + 2x^3 + 4 = 0$.

How did we get the derivative of $\arctan$ again? Differentiate $\tan(\arctan(x)) = x$

and write $u = \arctan(x)$:

$$\frac{1}{\cos^2(u)} \arctan'(x) = 1.$$ 

Use the identity $1 + \tan^2(u) = 1/\cos^2(u)$ to write this as

$$(1 + \tan^2(u)) \arctan'(x) = 1.$$ 

But $\tan(u) = \tan(\arctan(x)) = x$ so that $\tan^2(u) = x^2$. And we have

$$(1 + x^2) \arctan'(x) = 1.$$ 

Now solve for $\arctan'(x)$:

$$\arctan'(x) = \frac{1}{1 + x^2}.$$ 

Homework

1. Find all critical points for the following functions. If there are infinitely many, indicate their structure. For $f(x) = \cos(x)$ for example, the critical points can be written as $\pi/2 + k\pi$, where $k$ is an integer.
   a) $f(x) = x^4 - 3x^2$.
   b) $f(x) = 3 + \sin(\pi x)$
   c) $f(x) = \exp(-x^2)x^2$.
   d) $f(x) = \cos(\sin(x))$

2. For the following functions, find all the maxima and minima using the second derivative test:
   a) $f(x) = x \log(x)$, where $x > 0$.
   b) $f(x) = 1/(1 + x^2)$
   c) $f(x) = x^2 - 2x + 1$.
   d) $f(x) = 2x \tan(x)$, where $-\pi/2 < x < \pi/2$.

3. Verify that a cubic equation $f(x) = x^3 + ax^2 + bx + c$ always has an inflection point, a point where $f''(x)$ changes sign.
   Hint. Remember the wobbling table!

4. Depending on $c$, the function $f(x) = x^4 - cx^2$ has either one or three critical points. Find these points for a general $c$ and use the second derivative test to see whether they are maxima or minima. The answer will depend on $c$. Where does the answer change?

5. This creative problem is motivated from an interesting observation of Kent done last week in class. You can write down explicit formulas (of course you can experiment with graphing software) or just draw the graph. If you think no solution exists, indicate so.
   a) Find a function which has exactly 2 local maximum and 1 local minimum.
   b) Find a function which has exactly 2 local maxima and no local minimum.
Lecture 11: Worksheet

Critical points and extrema

Which rectangle of fixed area $xy = 1$ has minimal circumference $2x + 2y$?

We have to extremize the function

$$f(x) = 2x + \frac{2}{x}.$$

1. Differentiate the function $f$. For which $x$ is it continuous?
2. Find the critical points of $f$, the places where $f'(x) = 0$.
3. Sketch the graph of $f$ on the interval $(0, 4]$.

A related but much more difficult problem is to find the shape with fixed area 1 which has minimal circumference. A more advanced flavor of calculus allows to solve this: the calculus of variations.

So, which is the winner? You might have guessed. The circle. The rectangle example illustrates already that symmetry is often favored in extremization problems.
Lecture 12: Global extrema

In this lecture we look at super maxima. Local maxima are great, global maxima are the greatest. These extrema can occur at critical points of \( f \) or at the boundary of the domain, where \( f \) is defined.

A point \( p \) is called a global maximum of \( f \) if \( f(p) \geq f(x) \) for all \( x \). A point \( p \) is called a global minimum of \( f \) if \( f(p) \leq f(x) \) for all \( x \).

How do we find global maxima? We just make a list of all local extrema and boundary points, then pick the largest. Global extrema do not need to exist on the real line. The function \( f(x) = x^2 \) has a global minimum at \( x = 0 \) but no global maximum. We can however look at global maxima on finite intervals.

1. Find the global maximum of \( f(x) = x^2 \) on the interval \([-1, 4] \). Solution. We look for local extrema at critical points and at the boundary. Then we compare all these extrema to find the maximum or minimum. The critical points are \( x = 0 \). The boundary points are \(-1, 4 \). Comparing the values \( f(-1) = 1, f(0) = 0 \) and \( f(4) = 16 \) shows that \( f \) has a global maximum at \( 4 \) and a global minimum at \( 0 \).

2. Find the global maximum and minimum of the function \( f(x) = |x| \). The function has no absolute maximum as it goes to infinity for \( x \to \infty \). The function has no critical point on the domain of definition \( R \setminus \{0\} \) of the function \( f' \). To see the minimum, we have also to look at the point \( x = 0 \).

3. A soda can is a cylinder of volume \( \pi r^2 h \). The surface area \( 2\pi rh + 2\pi r^2 \) measures the amount of material used to manufacture the can. Assume the surface area is \( 2\pi \), we can solve the equation for \( h = (1 - r^2) / r = 1/r - r \). Solution: The volume is \( f(r) = \pi (r-r^3) \). Find the can with maximal volume: \( f'(r) = \pi - 3r^2 \pi = 0 \) showing \( r = 1 / \sqrt{3} \). This leads to \( h = 2 / \sqrt{3} \).

4. Take a US Letter size paper of 8 × 11 inches. If we cut out 4 squares of equal size at the corners, we can fold up the paper to a tray with width \((8 - 2x)(11 - 2x) \) and height \( x \). Find the \( x \in [0, 4] \) for which the volume \( f(x) = (8 - 2x)(11 - 2x)x = 4x^3 - 38x^2 + 88x \) is maximal. The solutions to \( f'(x) = 12x^2 - 76x + 88 = 0 \) are \( x = i(19 \pm \sqrt{97})/2 \) which is about 1.5 or 5. The second one is larger than 4. We see that

What is the minimal volume? This example illustrates that we might have to look at the boundary of the interval for extrema. Assume we have a function \( f \) which is differentiable except at some points \( a_1, \ldots, a_n \). We include the end points of the domain of definition in this list. The task is to find the global maximum. How do we proceed?

- 1. Evaluate the function at the point \( a_1, \ldots, a_n \).
- 2. Find the local maxima by looking at critical points \( b_1, \ldots, b_n \).
- 3. Find the maximum of \( f(a_1), f(a_2), \ldots, f(a_n), f(b_1), \ldots, f(b_n) \).

5. Find the global maxima and minima of the function \( f(x) = |x| - 2x^2 + x^3 \) on the interval \([-1, 2] \).

1. The correct size is \( 17/2 \times 11 \) inches we avoid fractions.
### Homework

1. Find the global maxima and minima of the function $f(x) = (x - 2)^2$ on the interval $[0, 3]$.

2. Find the global maximum and minimum of the function $f(x) = 2x^3 - 3x^2 - 36x$ on the interval $[-5, 5]$.

3. A candy manufacturer builds spherical candies. Its effectiveness is $A(r) - V(r)$, where $A(r)$ is the surface area and $V(r)$ the volume of a candy of radius $r$. Find the radius, where $f(r) = A(r) - V(r)$ has a global maximum for $r \geq 0$.

4. Let's look at the falling ladder again. But now $x$ denotes the angle, the ladder makes with the floor. Find the angle, where the distance $f(x)$ of the ladder to the wall-floor corner is maximal.
   
   P.S. You can assume the ladder has length 1 but it will not matter how long the ladder is.

5. a) The function $S(p) = -p \log(p)$ is called the entropy function. Find the probability $0 < p \leq 1$ which maximizes entropy. One of the most important principles in all science is that nature tends to maximize entropy. In some sense we compute here the number of maximal entropy.

   b) We can write $1/x = e^{-x \log(x)}$. Find the value $x$, where $x^{-x}$ has a local maximum which is the point where $x^4$ has a local minimum.
Lecture 12: Worksheet

Extrema with boundaries

The following famous problem is usually asked with the Statue of liberty. At Harvard, we of course want to use the John Harvard Statue. It is a common situation. You want to look at a statue. If you are too close below it, the viewing angle becomes small. If you are far away, the viewing angle decreases again. There is an optimal distance where the viewing angle is maximal.

At which distance \( x \) do you see most of the John Harvard Statue? Assume the part you want to see 4 to 9 feet higher than your eyes.

1. Verify that the angle you see from the statue is
   \[ f(x) = \arctan\left(\frac{9}{x}\right) - \arctan\left(\frac{4}{x}\right). \]

2. Differentiate \( f(x) \) to find the minimum.

3. Are there any boundary points or points where \( f \) is not differentiable?

4. Find the global maximum of \( f \).

5. Is there a global minimum of \( f \)?

Here is a graph of part of the function \( f \).
The rule

In this lecture, we look at a powerful rule to compute limits. This Hopital’s rule works miracles and solves all our remaining worries about limits:

**Hopital’s rule.** If $f, g$ are differentiable and $f(p) = g(p) = 0$ and $g′(p) \neq 0$, then

$$\lim_{x \to p} \frac{f(x)}{g(x)} = \frac{f′(p)}{g′(p)}.$$

Let see how it works:

1. Let prove the fundamental theorem of trigonometry again:

$$\lim_{x \to 0} \frac{\sin(x)}{x} = \lim_{x \to 0} \frac{\cos(x)}{1} = 1.$$

Why did we work so hard for this? Note that we used the fundamental theorem to derive the derivatives for $\cos$ and $\sin$ at all points. In order to apply l’Hopital, we had to know the derivative. Our work to establish the limit was not in vain.

The proof of the rule is almost comic in its simplicity if we compare it with how fantastically useful it is:

Since $f(p) = g(p) = 0$ we have $Df(p) = f(p + h)/h$ and $Dg(p) = g(p + h)/h$ so that for every $h > 0$ with $g(p + h) \neq 0$ the quantum l’Hopital rule holds:

$$\frac{f(p + h)}{g(p + h)} = \frac{Df(p)}{Dg(p)}.$$

Now take the limit $h \to 0$. The left side is what we want to know, the right side is a quotient of two limits which exist since $g′(p) \neq 0$. ¹

Sometimes, we have to administer a medicine twice. To use this, l’Hopital can be improved in that the condition $g′(0) = 0$ can be replaced by the requirement that the limit $\lim_{x \to p} f′(x)/g′(x)$ exists. Instead of having a rule which replaces a limit with an other limit (we cure a disease with a new one!) we formulate it in the way how it is actually used. The second derivative case could easily be generalized for higher derivatives. There is no need to memorize this. Just remember that you can check in several times to a hospital.

If $f(p) = g(p) = f′(p) = g′(p) = 0$ then $\lim_{x \to p} \frac{f(x)}{g(x)} = \frac{f''(p)}{g''(p)}$ if $g''(p) \neq 0$.

2. Find the limit $\lim_{x \to 0} (1 - \cos(x))/x^2$. Remember that this limit had also been pivotal to compute the derivatives of trigonometric functions. Solution: differentiation gives

$$\lim_{x \to 0} -\sin(x)/2x.$$

This limit can be obtained with l’Hopital again.

$$\lim_{x \to 0} -\sin(x)/(2x) = \lim_{x \to 0} -\cos(x)/2 = -1/2.$$

3. Find the limit $f(x) = (\exp(x^2) - 1)/\sin(x^2)$ for $x \to 0$.

4. What do you get if you apply l’Hopital to the limit $[f(x + h) - f(x)]/h$ as $h \to 0$?

5. Find $\lim_{x \to 0} x\sin(1/x)$. Solution. Write $y = 1/x$ then $\sin(y)/y$. Now we have a limit, where the denominator and nominator both go to zero.

The case when both sides converge to infinity can be reduced the other case by looking at $A = f/g = (1/g(x))/(1/f(x))$ which has the limit $g′(x)/g(x)(f′(x)/f(x)) = g′(x)/f′(x)((1/g)(1/f)) = g′/f′(f′/g′) = (g′/f′)^2$, so that $A = f′(p)/g′(p)$. We see:

If $\lim_{x \to p} f(x) = \lim_{x \to p} g(x) = \infty$ for $x \to p$ and $g′(p) \neq 0$, then

$$\lim_{x \to p} \frac{f(x)}{g(x)} = \frac{f′(p)}{g′(p)}.$$

2. What is the limit $lim_{x \to 0} x^2$? This answers the intriguing question: what is $\lim_{x \to 0} x^\alpha$?

Solution: Because $x^\alpha = e^{\alpha \log(x)}$, it is enough to understand the limit $x \log(x)$ for $x \to 0$.

$$\lim_{x \to 0} \frac{\log(x)}{1/x}.$$

Now the limit can be seen as the limit $(1/x)/(-1/x^2) = -x$ which goes to 0. Therefore the limit $lim_{x \to 0} x^\alpha = 1$ (We assume $x > 0$ to have real values $x^\alpha$)

3. Find the limit $\lim_{x \to 0} \frac{x^3 - 4x^4 + 1}{\sin(x)}$.

**Solution:** this is a case where $f(2) = f′(2) = g(2) = g′(2) = 0$ but $g′(0) = 2$. The limit is $f′/g′(2)/g′(2) = 2/2 = 1$.

Hopital’s rule always works in calculus situations, where functions are differentiable. The rule can fail if differentiability of $f$ or $g$ fails. Here is an other “rare” example:

4. **Deja Vu:** Find $\frac{\sqrt{x^3}}{\sin(\frac{1}{x})}$ for $x \to \infty$. L’Hopital gives $x/\sqrt{x^2 + 1}$ which in terms gives again $x/\sqrt{x^2}$. Apply l’Hopital again to get the original function. We got an infinite loop. If the limit is $A$, then the procedure tells that it is equal to $1/A$. The limit must therefore be 1. This case can be covered easily without l’Hopital: divide both sides by $x$ to get $\sqrt{1+1/x^2}$. Now, we can see the limit 1.

5. **Scarecrow:** given $f(x) = x \sin(1/x^4)e^{-1/x^2}$ and $g(x) = e^{-1/x}$. What is the limit $f(x)/g(x)$ as $x \to 0$. **Solution.** Since the functions $f$ and $g$ are not differentiable at $x = 0$ l’Hopital is not appropriate. The example appears in textbooks because the limit still exists. Look at $f/g = x \sin(1/x^4)$ which satisfies $|f(x)/g(x)| \leq |x|$ and converges to 0 for $x \to 0$.

¹Some books refer to the intermediate value theorem here. This is not necessary.

²It appears in http://mathworld.wolfram.com/LHospitalsRule.html
Given a differentiable function satisfying $g(0) = 0$. Verify that the limit $\lim_{x \to 0} f'(g(x))/g(x)$ is $f'(0)$. Solution: You check in the homework that the result is $f'(g(0))$.

### History

The rule appeared in the "first calculus book" the world has known. The book with name "Analyse des Infiniment Petits pour l’intelligence des Lignes Courbes" appeared in 1696 and was written by Guillaume de l'Hopital, a text if typeset in a modern font would probably fit onto 50-100 pages. It is now clear that the mathematical content of l'Hopital’s book is mostly due to Johannes Bernoulli who became a mathematical "mercenary" for l'Hopital: Clifford Truesdell write in his article "The New Bernoulli Edition", about this "most extraordinary agreement in the history of science": l'Hopital wrote: "I will be happy to give you a retainer of 300 pounds, beginning with the first of January of this year ... I promise shortly to increase this retainer, which I know is very modest, as soon as my affairs are somewhat straightened out ...

I am not so unreasonable as to demand in return all of your time, but I will ask you to give me at intervals some hours of your time to work on what I request and also to communicate to me your discoveries, at the same time asking you not to disclose any of them to others. I ask you even not to send here to Mr. Varignon or to others any copies of the writings you have left with me; if they are published, I will not be at all pleased. Answer me regarding all this ..." Bernoulli’s response is lost, but a letter from l'Hopital indicates that it was quickly accepted. From this point on, Bernoulli was a "giant enchained" (Truesdell). Clifford Truesdell also mentions that the book of l'Hopital has remained the standard for Calculus for a century.

### Homework

1. For the following functions, find the limits as $x \to 0$:
   a) $(x^2 - x)/\sin(x)$
   b) $(\exp(x) - 1)/(\exp(3x) - 1)$
   c) $\sin^2(3x)/\sin^3(5x)$
   d) $x + \log(x)x + \frac{\sin(x)}{x}$
   e) $\sin(\sin(\sin(\exp(\sin(x)))))/\sin(\sin(\exp(\sin(x))))$.

2. For the following functions, find the limits as $x \to 1$:
   a) $(x^2 - 1)/(\cos(x - 1) - 1)$
   b) $(\exp(x) - e)/(\exp(3x) - e^3)$
   For the following functions, find the limits as $x \to \infty$:
   c) $(x^2 - 1)/\sqrt{x^2 + 1}$
   d) $(x - 4)/(4x + \sin(x) + 8)$

3. Here is an FUD attempt on l’Hopital’s rule: Define $f(x) = x + \cos(x)\sin(x)$ and $g(x) = \exp(\sin(x))(x + \cos(x)\sin(x))$.
   a) Show that $f'(x)/g'(x)$ converges to zero as $x \to \infty$.
   b) Verify that $f(x)/g(x)$ remains in the interval $[1/e, e]$ but does not converge. The function is not differentiable at $\infty$. There is no problem with l’Hopital.

4. Take the same functions from the previous example and look at the limit $f(x)/g(x)$ for $x \to 0$. Now things are nice and dandy because the functions are differentiable at 0.

5. a) Assume a function $f(x)$ satisfies $f(0) = 0$ and $f'(0) \neq 0$. Verify the following formula
   \[ \lim_{x \to 0} f(ax)/f(bx) = a/b. \]
   b) Given a differentiable function $g$ satisfying $g(0) = 0$ and a differentiable function $f$. Verify that
   \[ \lim_{x \to 0} \frac{f(g(x))}{g(x)} = f'(0). \]
Lecture 13: Worksheet

Hopital’s rule

1. What does l’Hopital’s rule say about
\[ \lim_{x \to 0} \frac{\exp(2x) - 1}{x} . \]

2. Apply l’Hopital’s rule to get the limit of
\[ f(x) = \frac{\sin(100x)}{\sin(200x)} \]
for \( x \to 0 \).
Lecture 14: Newton’s method

In the intermediate value theorem lecture, we have seen a simple method to find a root of a function: start with an interval \([a, b]\) such that \(f(a) < 0\) and \(f(b) > 0\), then successively half the interval always choosing the side on which the function takes different signs at the boundary. We are then \((b - a)/2^n\) close to the root in \(n\) steps. If the function is differentiable we can do much better and use the value of the derivative at a boundary point to get closer. If we draw a tangent at \((x, f(x))\), then

\[
T(x) = x - \frac{f(x)}{f'(x)}.
\]

Newton’s method is the process to apply this map again and again until we are sufficiently close to the root. It is an extremely fast method to find the root of a function. Start with a point \(x\), then compute a new point \(x_1 = T(x)\), where

\[
T(x) = x - \frac{f(x)}{f'(x)}.
\]

Now iterate this again and again.

The Newton map is defined as

\[
T(x) = x - \frac{f(x)}{f'(x)}.
\]

Newton’s method is the process to apply this map again and again until we are sufficiently close to the root. It is an extremely fast method to find the root of a function. Start with a point \(x\), then compute a new point \(x_1 = T(x)\), where

\[
T(x) = x - \frac{f(x)}{f'(x)}.
\]

Now iterate this again and again.

1. If \(f(x) = ax + b\), we reach the root in one step.
2. If \(f(x) = x^2\) then \(T(x) = x - x^2/(2x) = x/2\). We get exponentially fast to the root 0 but not as fast as the method promises. Indeed, the root is also a critical point which slows us down.
3. The Newton map brings us to infinity if we start at a critical point.

Newton used the method to find the roots of polynomials. The method is so fast that it amazes: Starting 0.1 close to the point, we have after one step 0.01 after 2 steps 0.0001 after 3 steps 0.00000001 and after 4 steps 0.0000000000000001.

The Newton method converges extremely fast to a root \(f(p) = 0\) if \(f'(p) \neq 0\) if we start sufficiently close to the root.

In 10 steps we can get a \(2^{10} = 1024\) digits accuracy. Having a fast method to compute roots is useful. For example in computer graphics, where things can not be fast enough. Also in number theory, when working with integers having thousands of digits the Newton method can help. Besides that, there is theoretical use which can explain for example the stability of planetary motion.

4. Verify that the Newton map \(T(x)\) in the case \(f(x) = (x - 1)^3\) has the property that we approach the root \(x = 1\). Solution. You see that the approach is not that fast: we get \(T(x) = x + (1 - x)/3 = (1 + 2x)/3\). It converges exponentially fast, but not superexponential. The reason is that the derivative at \(x - 1\) is not zero. That slows us down.

If we have several roots, and we start at some point, to which root will the Newton method converge? Does it all converge? This is an interesting question. It is also historically intriguing because it is one of the first cases, where “chaos” can be observed at the end of the 19th century.

5. Find the Newton map in the case \(f(x) = x^2 - 1\). Solution \(T(x) = x - (x^2 - 1)/(5x^2)\).

If we look for roots in the complex like for \(f(x) = x^2 - 1\) which has 5 roots in the complex plane, the basin of attraction of each of the points is a complicated set, a so called Newton fractal. Here is the picture:
Let’s compute $\sqrt{2}$ to 12 digits accuracy - by hand! We want to find a root $f(x) = x^2 - 2$. The Newton map is $T(x) = x - (x^2 - 2)/(2x)$. Let’s start with $x = 1$.

$$T(1) = 1 - (1 - 2)/2 = 3/2$$

$$T(3/2) = 3/2 - ((3/2)^2 - 2)/3 = 17/12$$

$$T(17/12) = 577/408$$

$$T(577/408) = 665857/470832$$

This is already $1.6 \cdot 10^{-12}$ close to the real root!

To find the cube root of 10 we have to find a root of $f(x) = x^3 - 10$. The Newton map is $T(x) = x - (x^3 - 10)/(3x^2)$. If we start with $x = 2$, we get the following steps: 2, 13/6, 3277/1521, 105569067476/49000820427. After three steps we have a result which is already $2.2 \cdot 10^{-9}$ close to the root.

The Newton method is an incredibly fast algorithm to get roots $x_0$ of equations. Simply scrumtrulescent.

### Homework

1. Find the Newton map $T(x) = x - f(x)/f'(x)$ in the following cases
   a) $f(x) = x^3$
   b) $f(x) = e^x$
   c) $f(x) = e^{-x^2}$
   d) $f(x) = 2\tan(x)$.

2. a) The sinc function $f(x) = \sin(x)/x$ has a root between 1 and 4. We get closer to the root by doing a Newton step starting with $x = \pi/2$. Do this step

3. The Newton map is handy to compute square roots. Assume we can’t find the square root of 99. We have to solve $\sqrt{99} = x$ or $f(x) = x^2 - 99 = 0$. Perform two Newton steps $T(x) = x - (x^2 - 99)/(2x)$ starting at $x = 10$.

4. a) Find the Newton step $T(x) = x - f(x)/f'(x)$ in the case $f(x) = 1/x$ and $f(x) = x^6$.
   b) Find the Newton step $T(x)$ in general if $f(x) = x^\alpha$, where $\alpha$ is a real number.

5. A chaotic Newton map. Verify that the Newton map in the case $f(x) = (4 - 3/x)^{1/3}$ is the quadratic map $T(x) = 4x(1 - x)$. We will see a demonstration in class which shows that this map is a true random number generator. The Newton map does not converge.

The graph of the function $f(x)$ and a few Newton steps. The function is continuous on $(0, 1)$. Its derivative too except at $x = 2/3$. 
Lecture 14: Worksheet

Newton Method

1. In the following graph, trace the two Newton steps already done. Add one more!

2. In the following graph, try a few Newton steps. Let your starting point $x_0$ be around 0.4.

3. We will together compute the square root of 2 to an accuracy of 12 digits. Without computer.
Lecture 15: Review for first midterm

Major points

A function is **continuous**, if the closeness of \( x, y \) implies the closeness of \( f(x), f(y) \). Intermediate value theorem: \( f(a) > 0, f(b) < 0 \) implies \( f \) having a root in \((a, b)\).

At a local **extremum**, \( f'(x) = 0 \). If \( f''(x) > 0 \), it is a local minimum. If \( f''(x) < 0 \), it is a local maximum. Global extremum: compare local extrema and boundary values.

If \( f' > 0 \) then \( f \) is increasing, if \( f' < 0 \) it is **decreasing**. If \( f''(x) > 0 \) it is **concave up**, if \( f''(x) < 0 \) it is **concave down**. If \( f''(x) = 0 \) then \( f \) has a horizontal tangent.

Hopital tells that limits \( \lim_{x \to a} f(x)/g(x) \), where \( f(p) = g(p) = 0 \) or \( f(p) = g(p) = \infty \) with \( g'(p) \neq 0 \) are given by \( f'(p)/g'(p) \).

With \( Df(x) = (f(x + h) - f(x))/h \) and \( S(x) = h(f(h) + f(2h) + \ldots + f(kh)) \) we have \( SDf(kh) = f(kh) - f(0) \) and \( DS(f(kh)) = f(kh) \). This is a preliminary fundamental theorem of calculus.

Roots of \( f(x) \) with \( f(a) < 0, f(b) > 0 \) can be obtained numerically by dissection or by applying the Newton map \( T(x) = x - f(x)/f'(x) \) again and again.

Algebra reminders

- **Healing**: \((a + b)(a - b) = a^2 - b^2\) or \(1 + a^2 + a^4 = (a^5 - 1)/(a - 1)\)
- **Denominator**: \(1/a + 1/b = (a + b)/(ab)\)
- **Exponential**: \(e^{a+b} = e^a e^b, e^{a-b} = e^a/(e^b)\)
- **Logarithm**: \(\log(ab) = \log(a) + \log(b), \log(a^b) = b\log(a)\)
- **Trig functions**: \(\cos^2(x) + \sin^2(x) = 1, 2\sin(x)\cos(x), \cos(2x) = \cos^2(x) - \sin^2(x)\)
- **Square roots**: \(a^{1/2} = \sqrt{a}, a^{-1/2} = 1/\sqrt{a}\)

Important functions

- **Polynomials**: \(x^3 + 2x^2 + 3x + 1\)
- **Rational functions**: \((x + 1)/(x^2 + 2x + 1)\)
- **Trig functions**: \(2\cos(3x)\)

Important derivatives

- **Exponential**: \(5e^{3x}\)
- **Logarithm**: \(\log(3x)\)
- **Inverse trig functions**: \(\arctan(x)\)

Differentiation rules

- **Addition rule**: \(f(x) + g(x)\)
- **Scaling rule**: \(af(x)\)
- **Product rule**: \(fg'(x) + f'g(x)\)
- **Quotient rule**: \(\frac{f(x)g'(x) - f'(x)g(x)}{g^2(x)}\)
- **Chain rule**: \(f(g(x))\)
- **Easy rule**: simplify before deriving

Extremal problems

1. Build a fence of length \( 1 \) with \( x \) and \( y \).
2. Find \( \lim_{x \to \infty} \cos(3x) \cos(5x) \).
3. Find \( \lim_{x \to 0} \sin(4x)/x \).
4. Find \( \lim_{x \to \infty} e^{-x^2} \).

Limit examples

- **Heal directly**: \(\lim_{x \to 0} \sin(x)/x = \text{H}0/\text{0}\)
- **Heal twice**: \(\lim_{x \to \infty} e^{-x^2} = \text{H}\infty/\text{0}\)
- **No work necessary**: \(\lim_{x \to -\infty} \exp(x)/(1 + \exp(x)) = \text{H}\)

Important things

Summation and taking differences is at the hart of calculus.

The 3 major types of discontinuities are jump, oscillation, infinity.

The Newton method is an algorithm to find roots.

Remember the fundamental theorem of trigonometry \(\lim_{x \to 0} \sin(x)/x = 1\).

The derivative of \( f(x) = \sqrt{x} \) as \( h \to 0 \). It is called rate of change.

The rule \( (1 + h)^{1/h} = 1 + h \) leads to \( \exp(x) = \exp(x) \).

More Examples

1. Find \( \lim_{x \to 1} (x^{1/4} - 1)/(x^{1/5} - 1) \). Answer: 5/4.
2. Find \( \lim_{x \to 1} \sin(4x)/(x - 1) \). Answer: 4.
3. Find \( \lim_{x \to -1} \frac{\sqrt{x} - 1}{x + 1} \). Answer: -1/6
4. Find \( \arcsin(\sqrt{3}/2) \). Answer: 10x(1 - 25x^4)^{-1/2}
5. Is \( 1/\log|x| \) continuous at \( x = 0 \). Answer: yes
6. Is \( \log(1/x) \) continuous at \( x = 0 \). Answer: no
Lecture 15: Worksheet

Mind map

Produce your own mind map of the course. Here are some starting points. On the back is a suggestion.

On the abac
Lecture 16: Mean value theorem

In this lecture, we look at the **mean value theorem** and a special case called **Rolle’s theorem**. It is important later when we study the fundamental theorem of calculus. Unlike the intermediate value theorem which applied for continuous functions, the mean value theorem involves derivatives:

**Mean value theorem:** For a differentiable function \( f \) and an interval \((a, b)\), there exists a point \( p \) inside the interval such that

\[
\frac{f(b) - f(a)}{b - a} = f'(p).
\]

Here are a few examples which illustrate this:

1. The function \( f(x) = x^2 + ax + b \) has roots at \( u = (-a \pm \sqrt{a^2 - 4b})/2 \). The derivative \( 2x + a = 0 \) is zero for \( x = a/2 \).
2. \( f(x) = cx \), then \( f'(x) = cx \) and \( f(b) - f(a) = (cb - ca)/(b - a) = c \). So, every point \( x \) has the derivative \( c \).
3. \( f(x) = \arcsin(x) \) has the property that for any \( x, y \) in \((-1, 1)\), we have \( |\arcsin(y) - \arcsin(x)| \geq |x - y| \). **Solution.** The derivative of \( \arcsin(x) \) is \( 1/\sqrt{1-x^2} > 1 \).
4. A biker drives with velocity \( f'(t) \) at position \( f(b) \) at time \( b \) and at position \( a \) at time \( a \). The value \( f(b) - f(a) \) is the distance traveled. The fraction \([f(b) - f(a)]/(b - a)\) is the average speed. The theorem tells that there was a time when the bike had exactly the average speed.
5. The function \( f(x) = \sqrt{1-x^2} \) has a graph on \((-1, 1)\) on which every possible slope is taken. **Solution:** We can see this with the intermediate value theorem because \( f'(x) = x/\sqrt{1-x^2} \) gets arbitrary large near \( x = -1 \) or \( x = 1 \). The mean value theorem shows this too because we can take intervals \([a, b] = [-1, -1 + c]\) for which \([f(b) - f(a)]/(b - a) = f(-1 + c)/c \approx \sqrt{2}/c = 1/\sqrt{2} \) gets arbitrary large.

Why is the theorem true? The function \( h(x) = f(a) + cx \), where \( c = (f(b) - f(a))/(b - a) \) also connects the beginning and end point. The function \( g(x) = f(x) - h(x) \) has now the property that \( g(a) = g(b) \). If we can show that for such a function, there exists \( x \) with \( g'(x) = 0 \), then we are done. By tilting the picture, we have reduced the statement to a special case which is important by itself:

**Rolle’s theorem:** If \( f(a) = f(b) \) and \( f \) is differentiable, then there exists a critical point \( p \) of \( f \) in the interval \((a, b)\).

Here is the proof: If it were not true, then \( f'(x) \neq 0 \) and we would have \( f'(x) > 0 \) everywhere or \( f'(x) < 0 \) everywhere. This would mean however that \( f(b) > f(a) \) or \( f(b) < f(a) \).

Here is a second proof: Fermat’s theorem assures that there is a local maximum or local minimum of \( f \) in \((a, b)\). At this point the derivative is zero. This means \( f'(x) = 0 \).

We have also seen a related fact that if \( f \) is continuous and \( f(a) = f(b) \) then there is a local maximum or local minimum in the interval \((a, b)\). This fact is more general and applies to every continuous function. The derivative does not need to exist.

6. There is a point in \([0, 1]\) where \( f'(x) = 0 \) with \( f(x) = x(1 - x^2)(1 - \sin(px)) \). **Solution:** We have \( f(0) = f(1) = 0 \). Use Rolle.
7. Show that the function \( f(x) = \sin(x) + x(\pi - x) \) has a critical point \([0, \pi]\). **Solution:** The function is nonnegative and zero at 0, \( \pi \). It is also differentiable and so by Rolle’s theorem there is a critical point. Remark. We can not use Rolle’s theorem to show that there is a local maximum even so the extremal value theorem assures us that this exist.
8. Verify that the function \( f(x) = 2x^3 + 3x^2 + 6x + 1 \) has only one real root. **Solution:** There is one real root by the intermediate value theorem: \( f(-1) = -4, f(1) = 12 \). Assume
there would be two roots. Then by Rolle’s theorem there would be a value \( x \) where \( g(x) = f'(x) = 6x^2 + 6x + 6 \) has a root. But there is no root of \( g \). [The graph of \( g \) minimum at \( g'(x) = 6 + 12x = 0 \) which is 1/2 where \( g(1/2) = 21/2 > 0 \].

Who was the first to find the mean value theorem? It is not so clear. Joseph Louis Lagrange is one candidate. Also Augustin Louis Cauchy (1789-1857) is credited for a modern formulation of the theorem.

Homework

1. The function \( f(x) = 1 - |x| \) satisfies \( f(-1) = f(1) = 0 \) but there is no point where \( f'(x) = 0 \). Is this a counter example to Rolle’s theorem?

2. Use Rolle’s theorem and the intermediate value theorem to show that the function \( f(x) = x^3 + 3x + 1 \) has exactly one root. You do not have to find the root.

3. We look at the function \( f(x) = \log|x| + \sin(x) \) on the positive real line. Use the intermediate value theorem applied to \( f'(x) \) to assure that for every \( M > 0 \) there is a positive \( x \) for which \( f'(x) = M \). Use the mean value theorem to assure that we can find for every \( M \) two values \( a, b \) such that \( f(b) - f(a)/(b - a) = M \).

4. Cauchy’s mean value theorem states that for any two differentiable function and any interval \( (a, b) \), there exists \( c \) for which \( (f(b) - f(a))g'(c) = (g(b) - g(a))f'(c) \). To prove this, define the function \( h(x) = (f(b) - f(a))(g(x) - g(a)) - (g(b) - g(a))(f(x) - f(a)) \).

a) Verify that \( h(a) = h(b) = 0 \).

b) Compute \( h'(x) \).

c) Use Rolle’s theorem to verify that there is a \( c \) for which \( h'(c) = 0 \). Hint. If stuck, there is more explanation in http://en.wikipedia.org/wiki/Mean_value_theorem. But first give it a shot on your own.

5. Given the function \( f(x) = x \sin(x) \) and the function \( g(x) = \cos(x) \). Verify (using Cauchy’s mean value theorem) that there is a point \( p \in (0, \pi/2) \) for which \( f'(p)/g'(p) = -\pi/2 \). You do not have to find the point.

What about Michel Rolle? He lived from 1652 to 1719, mostly in Paris. No picture of him seems available. Rolle also introduced the \( n \)'th root notation like \( \sqrt[n]{x} \).
Lecture 16: Worksheet

The mean value theorem

In this class, we have at various places looked at calculus with discrete eyes, where

\[ Df(x) = \frac{f(x + h) - f(x)}{h}. \]

We look here at the question whether there is a discrete version of Rolle’s theorem. You may have the opportunity to find a new result. Note that quantum results hold in general for functions which are only continuous. No differentiability is needed.

This worksheet might give you an idea what research is about. You do not need the answer yet, whether a result works or not. It is exciting because nobody else does now simply because nobody has studied the question yet!

1. **Quantum Rolle:** Given an interval \([a, b]\) from which we assume that its length is larger than \(h\). Given a continuous function \(f\) such that \(f(a) = f(b) = 0\). Is it true that there is a point \(p\) in that interval for which \(Df(p) = 0\)? Play and doodle around with examples.

2. **Quantum mean value theorem:** Given an interval \([a, b]\) and a function \(f\). Is it true that there is a point \(p\) such that

\[ Df(p) = \frac{f(b) - f(a)}{b - a}. \]

Play around with examples.

3. Argue that you can ”tilt” the setting as in the continuum so that if the quantum Rolle result holds, then the quantum mean value theorem holds.
In this lecture, we once more cover extrema problems. We are interested in how extrema change when a parameter changes. Nature, economies, processes favor extrema. Extrema change smoothly with parameters. How come that the outcome is often not smooth? What is the reason that political change can go so fast once a tipping point is reached? One can explain this with mathematical models. We look at a simple example, which explains it. In reality, the situation is more complicated. In the "New York Times" of February 24, 2011, Jennifer E. Sims, the director of intelligence studies at Georgetown University’s School of Foreign Service and senior fellow at the Chicago Council on Global Affairs asked: Why, with the U.S. spending 80 billion dollars on intelligence, were we apparently surprised by recent regime changes in the Middle East? Why did change happen at all? These are complex questions. Obviously, some tipping point has been reached and the smallest event like the confiscation of a fruit stand in Tunisia or increasing food prizes in Egypt has produced change. In these complex examples, it will never be possible to understand everything. Let’s look here at a simple mathematical model which illustrates the general principle that:

If a local minimum ceases to become a local minimum, a new stable position is favored. This can be far away from the original situation.

To get started, let’s look at an extremization problem.

Find all the extrema of the function $f(x) = x^4 - x^2$. Solution: $f'(x) = 4x^3 - 2x$ is zero for $x = 0, 1/\sqrt{2}, -1/\sqrt{2}$. The second derivative is $12x^2 - 2$. It is negative for $x = 0$ and positive at the other two points. We have two local minima and one local maximum.

Now find all the extrema of the function $f(x) = x^4 - x^2 - 2x$. There is only one critical point. It is $x = 1$.

Something has happened from the first example to the second example. The local minimum to the left has disappeared. Assume the function $f$ measures the prosperity of some kind and $c$ is a parameter. We look at the position of the first equilibrium point of the function. Catastroph theorists usually assume the so called Delay assumption.

A stable equilibrium is here used as another name for a local minimum. A system state remains in a stable equilibrium until it disappears. If that happens, the system settles in a neighboring stable equilibrium.

A parameter value for which a stable minimum disappears is called a catastrophe.
A parameter value for which a local minimum disappears is called a catastrophes.

Bifurcation diagram: The picture shows the equilibrium points as they change in dependence of the parameter $c$. The vertical axes is the parameter $c$, the horizontal axes is $x$. At the bottom for $c=0$, we have three equilibrium points, two local minima and one local maximum. At the top for $c=1$ we have only one local minimum.

Catastrophes always go for the worse in the sense that the value decreases. It is not possible to reverse the process and have a catastrophe, where the minimum jumps up.

Look again at the above "movie" of graphs. But run it backwards and use the same principle. We do not end up at the position we started with. The new equilibrium stays the equilibrium. Decreasing the food prizes again did not reverse the process of change in Egypt for example.

Catastrophes are in general irreversible.

We see that in real life: It is easy to screw up a relationship, get sick, have a ligament torn or lose trust. Building up a relationship, getting healthy or gaining trust on the other hand happen slowly. Ruining a country or a company or losing a good reputation of a brand is very easy. It takes a long time to regain it.

Local minima can change discontinuously, when a parameter is changed. This can happen with perfectly smooth functions and smooth parameter changes.

3 Let's look at $f(x) = x^4 + cx^2$, where $-1 \leq c \leq 1$. We will look at that in class.

Homework

In this homework, we study a catastrophe for the function

$$f(x) = x^6 - x^4 + cx^2,$$

where $c$ is a parameter between 0 and 1.

1. a) Find all the critical points in the case $c = 0$ and analyze their stability. b) Find all the critical points in the case $c = 1$ and analyze their stability.

2. Plot the graph of $f$ for at least 10 values of $c$ between 0 and 1. You can of course use software, a graphing calculator or Wolfram alpha. Mathematica code is below.

3. If you change from $c = -0.3$ to 0.6 pinpoint the value for the catastrophe and show a rough plot of $c \rightarrow f(x_c)$, the value at the first local minimum $x_c$ in dependence of $c$. The text above provides this graph for an other function. It is the graph with a discontinuity.

4. If you change back from $c = 0.6$ to 0.3 pinpoint the value for the catastrophe (it will be different from the one in the previous question).

5. Sketch the bifurcation diagram. That is, if $x_k(c)$ is the $k$-th equilibrium point, then draw the union of all graphs of $x_k(c)$ as a function of $c$ (the $c$-axes pointing upwards). As in the two example provided, draw the local maximum with dotted lines.

Manipulate[ Plot[x^6 - x^4 + c x^2, {x, -1, 1}], {c, 0, 1}]
Lecture 17: Worksheet

Catastrophes

We see here graphs of the function $f(x) = x^4 - cx^2$ for $c$ between 0 and 1:

1. Draw the bifurcation diagram in this case. The vertical axes is the $c$ axes.
Math 1A: introduction to functions and calculus

Lecture 18: Riemann integral

In this lecture we define the integral \( \int_a^b f(t) \, dt \) if \( f \) is a differentiable function and compute it for some basic functions.

First a reminder. We have defined the Riemann sums
\[
S_f(f) = h \left( f(0) + f(h) + f(2h) + \ldots + f(kh) \right),
\]
where \( k \) is the largest integer such that \( kh < x \). Let’s write \( S_n \) if we want to stress that the parameter \( h = 1/n \) was used in the sum. We define the integral as the limit of these sums \( S_n \) when the mesh size \( h = 1/n \) goes to zero.

Define
\[
\int_0^1 f(t) \, dt = \lim_{n \to 0} S_n f(x).
\]

Remark: Many calculus books define the Riemann integral using partitions \( x_0 < x_1 < \ldots < x_n \) of points of the interval \([0, x]\) such that the maximal distance \((x_{k+1} - x_k)\) between neighboring \( x_j \) goes to zero. The Riemann sum is then \( S_n = \sum_j f(y_j)(x_{j+1} - x_j) \), where \( y_j \) is arbitrarily chosen inside the interval \([x_j, x_{j+1}]\). For continuous functions, the limiting result is the same the \( S(f) \) sum done here. There are numerical reasons to allow more general partitions because it allows to adapt the mesh size: use more points where the function is complicated and keep a wide mesh, where the function does not change much. This leads to numerical analysis of integrals.

1. Let \( f(x) = c \) be constant everywhere. Now \( \int_0^1 f(t) \, dt = cx \). We can see also that\( cnx/n \leq S_n f(x) \leq c(n+1)x/n \).

2. Let \( f(x) = cx \). The area is half of a rectangle of width \( x \) and height \( cx \) so that the area is \( cx^2/2 \). Remark: we could also have added up the Riemann sum but that is more painful: for every \( h = 1/n \), let \( k \) be the largest integer smaller than \( xn = x/h \). Then (remember Gauss’s punishment?)
\[
S_n f(x) = \frac{1}{n} \sum_{j=1}^{k} \frac{cj}{n} = \frac{ck(k+1)/2}{n^2}.
\]
Taking the limit \( n \to \infty \) and using that \( k/n \to x \) shows that \( \int_0^x f(t) \, dt = cx^2/2 \).

3. Let \( f(x) = x^2 \). In this case, we can not see the numerical value of the area geometrically. But since we have computed \( S[x^2] \) in the first lecture of this course and seen that it is \( [x^3]/3 \) and since we have defined \( S_n f(x) \to \int_0^x f(t) \, dt \) for \( h \to 0 \) and \( [x^3] \to x^3 \) for \( h \to 0 \), we know that
\[
\int_0^x t^2 \, dt = \frac{x^3}{3}.
\]
This example actually computes the **volume of a pyramid** which has at distance \( t \) from the top an area \( t^2 \) cross section. Think about \( t^2 dt \) as a slice of the pyramid of area \( t^2 \) and height \( dt \). Adding up the volumes of all these slices gives the volume.

The other equalities are the same since \( \exp t \) is a positive function.

### Linearity of the integral (see homework) \( \int_a^b f(t) + g(t) \, dt = \int_a^b f(t) \, dt + \int_a^b g(t) \, dt \)

and \( \int_a^b \lambda f(t) \, dt = \lambda \int_a^b f(t) \, dt \).

### Upper bound: If \( 0 \leq f(x) \leq M \) for all \( x \), then \( \int_a^b f(t) \, dt \leq Mx \).

4 \( \int_0^1 \sin^2(\sin(\sin(t))) / x \, dt \leq x \). **Solution.** The function \( f(t) \) inside the interval is nonnegative and smaller or equal to 1 The graph of \( f \) is therefore contained in a rectangle of width \( x \) and height 1.

We see that if two functions are close then their difference is a function which is included in a small rectangle and therefore has a small integral:

If \( f \) and \( g \) satisfy \( |f(x) - g(x)| \leq c \), then

\[
\int_0^1 |f(x) - g(x)| \, dx \leq cx.
\]

We know identities like \( S_n[\] \( t^n \) and \( S_n[\exp(x)] = \exp_n(x) \) already. Since \( [x]_k^d - [x]_k^d \to 0 \) we have \( S_n[x]^d - S_n[x]^d \to 0 \) and from \( S_n[x] = [x]_k^d / (k + 1) \).

The other equalities are the same since \( \exp_n(x) = \exp \to 0 \). This gives us:

### Homework

1. a) Find the integral \( \int_0^1 t^3 + 4t^3 + e^t \, dt \).
   
   b) Calculate \( \int_0^1 t^3 - t + t^2 \, dt \).
   
   c) Find \( \int_{-\pi}^{3\pi} \cos(t) \, dt \).

2. Verify that the following statements hold for differentiable functions \( f, g \) and \( a < b < c \) and any real number \( \lambda \). You can argue geometrically with areas.
   - \( \int_a^b f(x) \, dx + \int_a^b g(x) \, dx = \int_a^b f(x) + g(x) \, dx \)
   - \( \int_a^b \lambda f(x) \, dx = \lambda \int_a^b f(x) \, dx \)
   - \( 0 \leq m \leq f(x) \leq M \) implies \( (b-a)m \leq \int_a^b f(x) \, dx \leq (b-a)M \).

3. a) Verify that every differentiable function \( f \) can be written as a difference of two nonnegative functions. To do so, show that \( g(x) = \max(f(x), 0) \) and \( h(x) = \max(-f(x), 0) \) have the property that \( f(x) = g(x) - h(x) \) and that \( g(x) \geq 0 \) and \( h(x) \geq 0 \).
   
   b) Draw the graphs of the two functions \( g(x), h(x) \) in the case \( f(x) = \sin(3x) \) where \( 0 \leq x \leq 2\pi \).

4. a) The region enclosed by the graph of \( x \) and the graph of \( x^3 \) has a propeller type shape as seen in the picture. Find its (positive) area.
   
   b) What is the integral \( \int_0^\pi |\sin(x)| \, dx \)?

5. a) Find \( \int_0^3 |x - 1| \, dx \). Distinguish cases.
   
   b) Find \( \int_0^\lambda f(x) \, dx \) for \( f(x) = |x - |x - 1|| \cdot |x - 2| \).
Lecture 18: Worksheet

Riemann sums

We look at the function $f(x) = \exp(-x^2)$. It is a function for which the integral $\int_0^x f(t) \, dt$ is not elementary. We can not express it with polynomials, trig, exponential functions or their inverses. We want here to get estimates for $\int_0^1 \exp(-x^2) \, dt$. 

Lecture 19: Fundamental theorem

In this lecture we prove the fundamental theorem of calculus for differentiable functions. This will allow us in general to compute integrals of functions which appear as derivatives.

We have seen earlier that with \( Sf(x) = h(f(0) + \cdots + f(kh)) \) and \( Df(x) = (f(x + h) - f(x))/h \) we have \( SDF = f(x) - f(0) \) and \( DSF(x) = f(x) \) if \( x = nh \). This becomes now:

**Fundamental theorem of calculus:** Assume \( f \) is differentiable. Then

\[
\int_a^b f(t) \, dt = f(b) - f(a) \quad \text{for differentiable functions.}
\]

Proof. Using notation of Euler we write \( A \sim B \) for "A and B are close" meaning \( A - B \to 0 \) for \( h \to 0 \). From \( Dsf(x) = f(x) \) for \( x = kh \) we have \( Dsf(x) \sim f(x) \) for \( kh < x < (k+1)h \) because \( f \) is continuous. We also know \( \int_a^t Df(t) \, dt \sim \int_a^t f(t) \, dt \) because \( Df(t) \sim f(t) \) uniformly for \( 0 \leq t \leq x \) by the definition of the derivative and the assumption that \( f' \) is continuous. We also know \( Dsf(x) = f(x) - f(0) \) for \( x = kh \). By definition of the Riemann integral \( Sf(x) \sim \int_0^x f(t) \, dt \) and so \( Sf(x) \sim \int_0^x Df(t) \, dt \).

\[
f(x) - f(0) \sim Sf(x) \sim \int_0^x Df(t) \, dt \sim \int_0^x f(t) \, dt
\]
as well as

\[
f(x) \sim DSf(x) \sim D \int_0^x f(t) \, dt \sim \frac{df}{dx} \int_0^x f(t) \, dt.
\]

1. \( \int_0^b 3t^2 \, dt = \frac{t^3}{3} \bigg|_0^b = \frac{b^3}{3} \). You can always leave such expressions as your final result. It is even more elegant than the actual number 390625/8.
2. \( \int_0^{\pi/2} \cos(t) \, dt = \sin(\pi/2) = 1 \). This is an important example which should become routine in a while.
3. \( \int_0^1 \sqrt{1+t} \, dt = \int_0^1 (1+t)^{1/2} \, dt = (1+t)^{3/2}/(3/2) \bigg|_0^1 = (1+x)^{3/2} - 1/(3/2) \). Here the difficulty was to see that the 1 + t in the interior of the function does not make a big difference.
4. Keep such examples in mind.
5. Also in this example \( \int_0^\infty \cos(t+1) \, dt = \sin(x+1) \bigg|_0^\infty = \sin(3) - \sin(1) \). The additional term +1 does not make a big dent.
6. \( \int_0^a \cot(x) \, dx \). This is an example where the anti derivative is difficult to spot. It is easy if we know where to look for: the function \( \log \sin(x) \) has the derivative \( \cos(x)/\sin(x) \). So, we know the answer is \( \log(\sin(x)) \big|_0^a = \log(\sin(\pi/2)) - \log(\sin(\pi/6)) = \log(1/\sqrt{2}) - \log(1/2) = -\log(2)/2 + \log(2)/2 = \log(2)/2 \).
7. The example \( \int_0^1 (1/t^2 - 9) \, dt \) is a bit challenging. We need a hint and write \( -6/(x^2 - 9) = 1/(x+3) - 1/(x-3) \). The function \( f(x) = \log(x+3) - \log(x-3) \) has therefore \( -6/(x^2 - 9) \) as a derivative. We know therefore \( \int_0^1 -6/(t^2 - 9) \, dt = \log(3 + x) - \log(3 - x) = \log(2) - \log(2) = \log(5/2) \). The original task is now \( -6/(x^2 - 9) \).
8. \( \int_0^a \cos(x) \, dx = \sin(x) \) because the derivative of \( \sin(x) \) is \( \cos(x) \) and \( \sin(x) \) is the antiderivative of \( \cos(x) \). If we differentiate this function, we get \( \cos(x) \).

2 Here is an important notation, which we have used in the example and which might at first look silly. But it is a handy intermediate step when doing the computation.

\[
F''_h = F(b) - F(a).
\]

We give reformulations of the fundamental theorem in ways in which it is mostly used:

If \( f \) is the derivative of a function \( F \) then

\[
\int_a^b f(x) \, dx = F(x)_b^a = F(b) - F(a).
\]

In some textbooks, this is called the "second fundamental theorem" or the "evaluation part" of the fundamental theorem of calculus. The statement \( \frac{d}{dx} \int_a^b f(t) \, dt = f(x) \) is the "antiderivative part" of the fundamental theorem. They obviously belong together and are two different sides of the same coin.

Here is a version of the fundamental theorem, where the boundaries are functions of \( x \).

Given \( g, h \) and if \( F \) is a function such that \( F' = f \), then

\[
\int_{h(x)}^{g(x)} f(t) \, dt = F(g(x)) - F(h(x)).
\]

9. \( \int_0^a \cos(t) \, dt = \sin(x^2) - \sin(x^4). \)

The function \( F \) is called an antiderivative. It is not unique but the above formula always give the right result.

Let's look at a list of important antiderivatives. You should have as many antiderivatives "hard wired" in your brain. It really helps. Here are the core functions you should know. They appear a lot.

Make your own table!
Meet Isaac Newton and Gottfried Leibniz. They have discovered the fundamental theorem of calculus. You can see from the expression of their faces how honored they are to find themselves on the same handout with Austin Powers and Doctor Evil. Culture clash ...

### Homework

1. For any of the following functions $f$, find a function $F$ such that $F' = f$.
   a) $e^x + \sin(3x) + x^3 + 5x$.
   b) $(x + 4)^3$.
   c) $1/x + 1/(x - 1)$.
   d) $\cos(x^2)2x + \sin(x^3)3x^2 + 1/\sqrt[2]{x}$

2. Find the following integrals by finding a function $g$ satisfying $g' = f$. We will learn techniques to find the function. Here, we just use our knowledge about derivatives:
   a) $\int_3^2 5x^4 + 4x^3 \, dx$.
   b) $\int_{\pi/4}^{\pi/2} \sin(3x) + \cos(x) \, dx$.
   c) $\int_{\pi/4}^{\pi/2} \sin^2(x) \, dx$.
   d) $\int_2^{-1} \frac{1}{x^3} \, dx$.

3. Evaluate the following integrals:
   a) $\int_2^3 2x \, dx$.
   b) $\int_1^3 \cosh(x) \, dx$. (Remember $\cosh(x) = (e^x + e^{-x})/2$.)
   c) $\int_0^{\pi/2} \frac{1}{\sin(x)} \, dx$.
   d) $\int_0^{2/3} \frac{1}{\sqrt{1-x^2}} \, dx$.

4. a) Compute $F(x) = \int_0^x \sin(t) \, dt$, then find $F'(x)$.
   b) Compute $G(x) = \int_{\cos(x)}^{\sin(x)} \exp(t) \, dt$ then find $G'(x)$

5. a) Be clever: Evaluate the following integral:
   $\int_0^\pi \sin(\sin(x)) \, dx$
   Give the answer and the reason in a short sentence.

   b) Be evil: Take a function $F$ of your choice. Find its derivative and call it $f$. Now pose an integration problem to find $\int_a^b f(x) \, dx$. Submit this problem to knill@math.harvard.edu I will select the most evil one.

   A good problem should lead to a short function $f$ but the integral $F$ should be difficult to find or guess. These problems will make perfect exam problems for the second midterm .... (evil laugh).

   You can submit your version of Problem 5b) electronically by email (knill@math.harvard.edu. Just send the function in the subject line. Mail can otherwise be empty). For any submission, independent how clever or evil, 10 points maximal will be added to your score (maxing up at 50). So, if your HW score of Lecture 19 is 45 and you submitted a function, it will be bumped to 50. If your HW score is 50 already you get nothing ... (more evil laugh).
Lecture 19: Worksheet

Fundamental theorem

Find the following integrals

1  $\int_{1}^{3} x^3 \, dx$

2  $\int_{-2}^{1} 1 - x^5 \, dx$

3  $\int_{0}^{1} \frac{1}{x^2 + 1} \, dx$

4  $\int_{2}^{4} \frac{1}{x} \, dx$

5  $\int_{1}^{4} x^{1/3} \, dx$

6  $\int_{1}^{3} \sqrt{1 + x^5} \, dx$

7  $\int_{1}^{2} \frac{1}{\sqrt{x}} + \frac{5}{x^2} \, dx$

8  $\int_{1}^{2} \frac{1}{1+x^2} \, dx$
# Lecture 20: Antiderivatives

We have looked at the integral $\int_a^b f(t) \, dt$ and seen that it is the signed area under the curve. We have seen that the area of the region below the curve is counted in a negative way. There is something else to mention:

For $x < 0$, we define $\int_a^b f(t) \, dt$ as $-\int_b^a f(t) \, dt$. This is compatible with the fundamental theorem $\int_a^b f(t) \, dt = f(b) - f(a)$.

We call $g(x) = \int_a^b f(t) \, dt + C$ an anti-derivative of $g$. The constant $C$ is arbitrary and not fixed. As we will see below, we can often adjust the constant such that some condition is satisfied.

The fundamental theorem of calculus assured us that

The antiderivative is the inverse operation of the derivative. Two different anti derivatives differ by a constant.

Finding the anti-derivative of a function is much harder than finding the derivative. We will learn some techniques but it is in general not possible to give anti derivatives for even very simple functions.

1. **Find the anti-derivative of $f(x) = \sin(4x) + 20x^3 + 1/x$.** Solution: We can take the anti-derivative of each term separately. The antiderivative is $F(x) = -\cos(4x)/4 + 4x^4 + \log(x) + C$.

2. **Find the anti derivative of $f(x) = 1/\cos^2(x) + 1/(1-x)$.** Solution: we can find the anti derivatives of each term separately and add them up. The result is $F(x) = \cot(x) + \log[1-x] + C$.

We mentioned Galileo Galilei, who measured free fall motion with constant acceleration. Assume $s(t)$ is the position of the ball at time $t$. Assume the ball has zero velocity initially and is located at height $s(0) = 20$. We know that the velocity is $v(t)$ is the derivative of $s(t)$ and the acceleration $a(t)$ is constant equal to $-10$. So, $v(t) = -10t + C$ is the antiderivative of $a$. By looking at $v$ at time $t = 0$ we see that $C = v(0)$ is the initial velocity and so zero. We know now $v(t) = -10t$. We need to compute the antiderivative of $v(t)$. This is $s(t) = -10t^2/2 + C$. Comparing $t = 0$ shows $C = 20$. Now $s(t) = 20 - 5t^2$. The graph of $s$ is a parabola. If we give the ball an additional horizontal velocity, such that time $t$ is equal to $x$ then $s(x) = 20 - 5x^2$ is the visible trajectory. We see that jumping from 20 meters leads to a fall which lasts 2 seconds.

4. **The total cost is the antiderivative of the marginal cost of a good.** Both the marginal cost as well as the total cost are a function of the quantity produced. For instance, suppose the total cost of making $x$ shoes is 300 and the total cost of making $x + 4$ shoes is 360 for all $x$. The marginal cost is $60/4 = 15$ dollars. In general the marginal cost changes with the number of goods. There is additional cost needed to produce one more shoe if 300 shoes are produced. **Problem**: Assume the marginal cost of a book is $f(x) = 5 - x/100$ and that producing the first 10 books costs 1000 dollars. What is the total cost of producing 100 books? **Answer**: The anti derivative $5 - x/100$ of $f$ is $F(x) = 5x - x^2/100 + C$ where $C$ is a constant. By comparing $F(10) = 1000$ we get $50 - 1000/100 + C = 1000$ and so $C = 951$. The result is $951 + 5 \cdot 100 - 10'000/100 = 1351$. The average book prize has gone down from 100 to 13.51 dollars.

A function $f$ is called elementary, if it can be constructed using addition, subtraction, multiplication, division, compositions from polynomials or roots. In other words, an elementary function is built up with functions like $x^3, \sqrt{x}, \exp, \log, \sin, \cos$ and arcsin, arccos, arctan.

5. **The function $f(x) = \sin(\pi + \sqrt{x} + x^2)) + \log(1 + \exp((x^2 + 1)/(x^2 + 1))) + (\arctan(e^x))^{1/3}$ is an elementary function.**

6. **The anti derivative of the sinc function is called the sine-integral**

$$Si(x) = \int_0^x \frac{\sin(t)}{t} \, dt.$$

The function $Si(x)$ is not an elementary function.
The offset logarithmic integral is defined as

$$\text{Li}(x) = \int_2^x \frac{dt}{\log(t)}$$

It is a specific anti-derivative. It is a good approximation of the number of prime numbers less than $x$. The graph below illustrates this. The second stair graph shows the number $\pi(x)$ of primes below $x$. For example, $\pi(10) = 4$ because 2, 3, 5, 7 are the only primes below it. The function $\text{Li}$ is not an elementary function.

The error function

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} \, dt$$

is important in statistics. It is not an elementary function.

### Numerical evaluation

What do we do when we have can not find the integral analytically? We can still compute it numerically. Here is an example: the function $\sin(\sin(x))$ also does not have an elementary antiderivative. But we can compute the integral numerically with a computer algebra system like Mathematica:

```mathematica
NIntegrate[Sin[Sin[x]], {x, 0, 10}]
```

### Pillow problems

We do not assign homework over spring break. If you have time, here are some integration riddles. We will learn techniques to deal with them. If you can not crack them, no problem. Maybe pick one or two and keep thinking about it over spring break. They make also good pillow problems, problems to think about while falling asleep. Try it. Sometimes, you might know the answer in the morning. Maybe you can guess a function which has $f(x)$ as a derivative.

1. $f(x) = \log(x)/x$.
2. $f(x) = \frac{1}{1-x}$.
3. $f(x) = \tan^2(x)$.
4. $f(x) = \cos^4(x)$.
5. $f(x) = \frac{1}{2\log(x)}$.

---

Lecture 20: Worksheet

Anti derivatives

Here are some trickier anti derivative puzzles. We still have no integration techniques and must rely on intuition and experiments to find the derivatives.

It is often a puzzle because we can try to combine derivatives of known functions to get the given function.

1. Find the anti-derivative of the function
   \[ f(x) = \frac{1 + x}{1 - x} \]
   
   **Hint.** First compute the anti derivative of
   \[ g(x) = \frac{1}{1 - x} \].
   Can you combine \( f \) and \( g \) in some way to make it fit?

2. Find the anti derivative of the function
   \[ f(x) = \sin(x^3)3x^2 \].

   **Hint.** Think about the product rule.

3. Find the anti-derivative of the function
   \[ f(x) = \sin(\sin(x))\cos(x) \].

   **Hint.** Think about the chain rule.

4. Find the anti-derivative of the function
   \[ f(x) = 2x\sin(x) + x^2\cos(x) \].

   **Hint.** Think about the product rule.

5. Find the anti-derivative of the function
   \[ f(x) = e^{e^x} \cdot e^{e^{e^x}} \cdot e^{e^{e^{e^x}}} \cdot e^{e^{e^{e^{e^x}}}} \cdot e^{e^x} \].

   **Hint.** There is no hint.
Lecture 21: Area computation

If \( f(x) \geq 0 \), then \( \int_a^b f(x) \, dx \) is the area under the graph of \( f(x) \) and above the interval \([a, b]\) on the x axes.

As you have seen in a homework, any function can be written as \( f(x) = f^+(x) - f^-(x) \), where \( f^+(x) \geq 0 \) and \( f^-(x) \geq 0 \). This means that we can write any integral \( \int_a^b f(x) \, dx \) as the difference of the area above the graph minus the area below the graph.

\[
\int_a^b f(x) \, dx = \int_a^b f^+(x) - f^-(x) \, dx.
\]

Here is the most common situation:

If a region is enclosed by two graphs \( f \leq g \) and \( x \) is also enclosed between \( a \) and \( b \) then its area is \( \int_a^b g(x) - f(x) \, dx \).

1. Find the area of the region enclosed by the x-axes, the y-axes and the graph of the cos function. Solution: \( \int_{\pi/2}^0 \cos(x) \, dx = 1 \).

2. Find the area of the region enclosed by the graphs \( f(x) = x^2 \) and \( f(x) = x^4 \).

3. Find the area of the region enclosed by the graphs \( f(x) = 1 - x^2 \) and \( g(x) = x^4 \).

4. Find the area of the region enclosed by a half circle of radius 1. Solution: The half circle is the graph of the function \( f(x) = \sqrt{1 - x^2} \). The area under the graph is \( \int_{-1}^1 \sqrt{1 - x^2} \, dx \).

Finding the anti-derivative is not so easy. We will find techniques to do so, for now we pop it together: we know that \( \arcsin(x) \) has the derivative \( 1/\sqrt{1 - x^2} \) and \( x\sqrt{1 - x^2} \) has the derivative \( \sqrt{1 - x^2} - x^2/\sqrt{1 - x^2} \). The sum of these two functions has the derivative \( \sqrt{1 - x^2} - (1 - x^2)/\sqrt{1 - x^2} = 2\sqrt{1 - x^2} \). We find the anti derivative to be \( (x\sqrt{1 - x^2} + \arcsin(x))/2 \). The area is therefore

\[
\left. \frac{x\sqrt{1 - x^2} + \arcsin(x)}{2} \right|_{-1}^1 = \frac{\pi}{2}.
\]

5. Find the area of the region between the graphs of \( f(x) = 1 - |x|^{1/4} \) and \( g(x) = -1 + |x|^{1/4} \).
Find the area under the curve of \( f(x) = \frac{1}{x^2} \) between \(-6\) and \(6\). Solution. \[
\int_{-6}^{6} \frac{-1}{x} \, dx = \left. -\ln|x| \right|_{-6}^{6} = -1 - 1/6 = -1/3.
\] There is something fishy with this computation because \( f(x) \) is nonnegative so that the area should be positive. But we obtained a negative answer. What is going on?

Find the area between the curves \( x = 0 \) and \( x = 2 + \sin(y) \). \( y = 2\pi \) and \( y = 0 \). Solution. We turn the picture by 90 degrees so that we compute the area under the curve \( y = 0 \), \( y = 2 + \sin(x) \) and \( x = 2\pi \) and \( x = 0 \).

The grass problem. Find the area between the curves \(|x|^{1/3}\) and \(|x|^{1/2}\). Solution. This example illustrates how important it is to have a picture. This is good advise for any "word problem" in mathematics.

Use a picture of the situation while doing the computation.

Homework

1. Find the area of the region enclosed by the graphs \( f(x) = x^3 \) and \( g(x) = \sqrt{|x|} \).
2. Find the area of the region enclosed by the four lines \( y = x \), \( y = 3 - x \), \( x = 1 \).
3. Find the area of the region enclosed by the curves \( y = 4\pi \), \( y = 2\pi \), \( x = -3 + \sin(3y) \), \( x = 2 + \sin(2y) \).
4. Write down an integral which gives the area of the elliptical region \( 4x^4 + y^2 \leq 1 \). Evaluate the integral numerically using Wolfram alpha, Mathematica or any other software.
5. The graphs \( \sin(x) \) and \( \cos(x) - 1 \) intersect at \( x = 2\pi \) and a point between. They define a humming bird region, consisting of a larger region and a tail region. Find the area of each and assume the bird has its eye closed.
Lecture 21: Worksheet

Area Computation

In this worksheet we look at other regions. In order to find the area we have to turn our heads.

1. Let's compute the area of the region enclosed by the lines $x = 0, x = \sqrt{y}, y = 0$ and $y = 4$. In order to solve such an area problem, we have to draw a picture. We started doing that. Find ways to find the area.

2. Let's compute the area of the region enclosed by the lines $x = 0, x = y^2, y = 0$ and $y = 2$. Now it's your turn to draw a picture and compute the area.
Math 1A: introduction to functions and calculus

Lecture 22: Volume computation

To compute the volume of a solid, we cut it into slices perpendicular along a line $x$. If $A(x)$ is the area of the slice and the body is enclosed between $a$ and $b$ then $V = \int_{a}^{b} A(x) \, dx$ is the volume. Think of $A(x)\,dx$ as the volume of a slice. The integral adds them up.

1. Compute the volume of a pyramid with square base length 2 and height 2. **Solution:** we can assume the pyramid is built over the square $-1 \leq x \leq 1$ and $-1 \leq y \leq 1$. The cross section area at height $h$ is $A(h) = (2 - h)^2$. Therefore,

$$V = \int_{0}^{2} (2 - h)^2 \, dh = \frac{8}{3}$$

This is base area 4 times height 2 divided by 3.

A **solid of revolution** is a surface enclosed by the surface obtained by rotating the graph of a function $f(x)$ around the $x$ axis.

The area of the cross section at $x$ of a solid of revolution is $A(x) = \pi f(x)^2$. The volume of the solid is $\int_{a}^{b} \pi f(x)^2 \, dx$.

2. Find the volume of a round cone of height 2 and where the circular base has the radius 1. **Solution.** This is a solid of revolution obtained by rotation the graph of $f(x) = x/2$ around the $x$ axes. The area of a cross section is $\pi x^2/4$. Integrating this up from 0 to 2 gives

$$\int_{0}^{2} \frac{\pi x^2}{4} \, dx = \frac{x^3}{12} \bigg|_{0}^{2} = \frac{2\pi}{3}.$$  

This is the height 2 times the base area $\pi$ divided by 3.

3. Find the volume of a half sphere of radius 1. **Solution:** The area of the cross section at height $h$ is $\pi(1 - h^2)$.

4. We rotate the graph of the function $f(x) = \sin(x)$ around the $x$ axes. But now we cut out a slice of 60 = $\pi/3$ degrees out. Find the volume of the solid. **Solution:** The area of a slice without the missing piece is $\pi \sin^2(x)$. The integral $\int_{0}^{\pi/6} \sin^2(x) \, dx$ is $\pi/2$ as derived in the lecture. Having cut out 1/6'th the area is $(5/6)\pi \sin^2(x)$. The volume is $\int_{0}^{\pi/6} (5/6)\pi \sin^2(x) \, dx = (5/6)\pi^2/2$. 

Homework

1. Find the volume of the paraboloid for which the radius at position $x$ is $1 - x^2$ and $x$ ranges from 0 to 1.

2. A catenoid is the surface obtained by rotating the graph of $f(x) = \cosh(x)$ around the $x$-axes. We have seen that the graph of $f$ is the chain curve, the shape of a hanging chain. Find the volume of the solid enclosed by the catenoid between $x = -1$ and $x = 1$.

   **Hint.** You might want to check first the identity $2\cosh(x)^2 = 1 + \cosh(2x)$ using the definition $\cosh(x) = (\exp(x) + \exp(-x))/2$.

3. A tomato is given by $z^2 + x^2 + 4y^2 = 1$. If we slice perpendicular to the $y$ axes, we get a circular slice $z^2 + x^2 \leq 1 - 4y^2$ of radius $\sqrt{1 - 4y^2}$.
   
   a) Find the area of this slice.
   
   b) Determine the volume of the tomato.
   
   c) Fix yourself a tomato salad by cutting a fresh tomato into slices and eat it, except for one slice which you staple to your homework paper as proof that you really did it.

4. As we have seen in the movie of the first class, Archimedes was so proud of his formula for the volume of a sphere that he wanted the formula on his tombstone. He wrote the volume of a half sphere of radius 1 as the difference between the volume of a cylinder of radius 1 and height 1 and the volume of a cone of base radius 1 and height 1. Relate the cross section area of the cylinder-cone complement with the cross section area of the sphere to recover his argument! If stuck, draw in the sand or soak in the bath tub for a while eating your tomato salad. There is no need to streak and scream "Eureka" when the solution is found.

5. Volumes were among the first quantities, Mathematicians wanted to measure and compute.

   One problem on Moscow Egyptian papyrus dating back to 1850 BC explains the general formula $h \left( a^2 + ab + b^2 \right)/3$ for a truncated pyramid with base length $a$, roof length $b$ and height $h$.

   a) Verify that if you slice the frustrum at height $z$, the area is $(a + (b - a)z/h)^2$.
   
   b) Find the volume using calculus.

   Here is the translated formulation from the papyrus:

   "You are given a truncated pyramid of 6 for the vertical height by 4 on the base by 2 on the top. You are to square this 4 result 16. You are to double 4 result 8. You are to square 2, result 4. You are to add the 16, the 8 and the 4, result 28. You are to take one-third of 6 result 2. You are to take 28 twice, result 56. See it is 56. You will find it right".

Lecture 22: Worksheet

Volume Computation

1. Find the volume of the solid that is formed by rotating the graph of \( y = x^2 \) around the \( x \)-axis, for \( 1 \leq x \leq 3 \).

2. Find the volume of the solid that is formed by rotating the graph of \( y = x^2 \) around the \( y \)-axis, for \( 1 \leq y \leq 3 \).

3. Derive the formula for the volume of a sphere (\( \frac{4}{3} \pi r^3 \)).

4. Find the volume of the solid of revolution for which the radius at height \( z \) is \( 2 - |z| \) and \( -1 \leq z \leq 1 \).

5. The solid of revolution for which the radius at position \( x \) is \( x^4 + 1 \) and \( x \in [-2, 2] \) is taken only above the \( xy \) plane as in the picture. Find the volume.
Lecture 23: Improper integrals

In this lecture, we look at integrals on infinite intervals or integrals, where the function can get infinite at some point. These integrals are called improper integrals. The area under the curve can remain finite or become infinite.

1 What is the integral \( \int_{1}^{\infty} \frac{1}{x^2} \, dx \)?

Since the anti-derivative is \(-\frac{1}{x}\), we have

\[
-\frac{1}{x} \bigg|_{1}^{\infty} = -1/\infty + 1 = 1.
\]

To justify this, compute the integral \( \int_{1}^{b} \frac{1}{x^2} \, dx = 1 - \frac{1}{b} \) and see that in the limit \( b \to \infty \), the value 1 is achieved.

In a previous lecture, we have seen a choking example similar to the following one:

2 \[
\int_{-1}^{1} \frac{1}{x^2} \, dx = -\frac{1}{x} \bigg|_{-1}^{1} = -1 - 1 = -2.
\]

This does not make any sense because the function is positive so that the integral should be a positive area. The problem is this time not at the boundary \(-1, 1\). The sore point is \(x = 0\) over which we have carelessly integrated over.

The next example illustrates the problem with the previous example better:

3 The computation

\[
\int_{0}^{1} \frac{1}{x^2} \, dx = \frac{1}{x} \bigg|_{0}^{1} = -1 + \infty.
\]

indicates that the integral does not exist. We can justify by looking at integrals

\[
\int_{a}^{1} \frac{1}{x^2} \, dx = -\frac{1}{x} \bigg|_{a}^{1} = -1 + \frac{1}{a}
\]

which are fine for every \(a > 0\). But this does not converge for \(a \to 0\).

Do we always have a problem if the function goes to infinity at some point?

4 Find the following integral

\[
\int_{0}^{1} \frac{1}{\sqrt{x}} \, dx.
\]

Solution: Since the point \(x = 0\) is problematic, we integrate from \(a\) to 1 with positive \(a\) and then take the limit \(a \to 0\). Since \(x^{-1/2}\) has the antiderivative \(x^{1/2}/(1/2) = 2\sqrt{x}\), we have

\[
\int_{a}^{1} \frac{1}{\sqrt{x}} \, dx = 2\sqrt{x} \bigg|_{a}^{1} = 2\sqrt{1} - 2\sqrt{a} = 2(1 - \sqrt{a}).
\]

There is no problem with taking the limit \(a \to 0\). The answer is 2. Even so the region is infinite its area is finite. This is an interesting example. Imaging this to be a container for paint. We can fill the container with a finite amount of paint but the wall of the region has infinite length.

5 Evaluate the integral \(\int_{0}^{1} \frac{1}{\sqrt{1 - x^2}} \, dx\). Solution: The antiderivative is \(\arcsin(x)\). In this case, it is not the point \(x = 0\) which produces the difficulty. It is the point \(x = 1\). Take \(a > 0\) and evaluate

\[
\int_{0}^{1-a} \frac{1}{\sqrt{1 - x^2}} \, dx = \arcsin(x) \bigg|_{0}^{1-a} = \arcsin(1) - \arcsin(0).
\]

Now \(\arcsin(1 - a)\) has no problem at limit \(a \to 0\). Since \(\arcsin(1) = \pi/2\) exists. We get therefore the answer \(\arcsin(1) = \pi/2\).

6 Rotate the graph of \(f(x) = 1/x\) around the \(x\)-axes and compute the volume of the solid between 1 and \(\infty\). The cross section area is \(\pi/x^2\). If we look at the integral from 1 to a fixed \(R\), we get

\[
\int_{1}^{R} \frac{\pi}{x^2} \, dx = -\frac{\pi}{x} \bigg|_{1}^{R} = -\pi/R + \pi.
\]

This converges for \(R \to \infty\). The volume is \(\pi\). This famous solid is called Gabriels trumpet. This solid is so prominent because if you look at the surface area of the small slice, then it is larger than \(dx/2\pi/x\). The total surface area of the trumpet from 1 to \(R\) is therefore larger than \(\int_{1}^{R} 2\pi/x \, dx = 2\pi(\log(R) - \log(1))\), which goes to infinity. We can fill the trumpet with a finite amount of paint but we can not paint its surface.
Finally, let’s look at the following example.

Evaluate the integral \( \int_0^\infty \sin(x) \, dx \). **Solution.** There is no problem at the boundary 0 nor at any other point. We have to investigate however, what happens at \( \infty \). Therefore, we look at the integral \( \int_b^0 \sin(x) \, dx = -\cos(x)\big|_b^0 = 1 - \cos(b) \). We see that the limit \( b \to \infty \) does not exist. The integral fluctuates between 0 and 2.

The next example leads to a topic in a follow-up course. It is not covered here, but could make you curious:

What about the integral \( I = \int_0^\infty \frac{\sin(x)}{x} \, dx \)?

**Solution.** The anti derivative is the Sine integral \( Si(x) \) so that we can write \( \int_b^0 \sin(x)/x \, dx = Si(b) \). It turns out that the limit \( b \to \infty \) exists and is equal to \( \pi/2 \) but this is a topic for a second semester course like Math 1b. The integral can be written as an alternating series, which converges and there are many ways to compute it: 1

Let’s summarize the two cases of improper integrals: infinitely long intervals and a point where the function becomes infinite.

1) To investigate the improper integral \( \int_a^\infty f(x) \, dx \) we look at the limit \( \int_b^a f(x) \, dx \) for \( b \to \infty \).

2) To investigate improper integral \( \int_0^b f(x) \, dx \) where \( f(x) \) is not continuous at 0, we take the limit \( \int_b^a f(x) \, dx \) for \( a \to 0 \).

**Homework**

1 Evaluate the integral \( \int_0^\frac{\pi}{2} \sin(x) + \cos(px) \, dx \).

2 Evaluate the following integrals
   a) \( \int_0^1 x/\sqrt{1-x^2} \, dx \).
   b) \( \int_0^1 1/\sqrt{1-x^2} \, dx \).

   Hint: For a) think about the chain rule \( d/dx f(g(x)) = f'(g(x))g'(x) \)

3 Evaluate the integral \( \int_0^1 (x^2)^{1/3} \, dx \). To make sure that the integral is fine, check whether \( \int_0^1 \) and \( \int_1^a \) work.

4 The integral \( \int_0^1 1/x \, dx \) does not exist. We can however take a positive \( b > 0 \) and look at
   \[ \int_{-b}^{-1} 1/x \, dx + \int_b^1 1/x \, dx = \log|b| - \log|1 - 2| + (\log|1| - \log|b|) = \log(2). \]

   This value is called the Cauchy principal value of the integral. Find the principal value of
   \( \int_{-4}^5 3/x^3 \, dx \) using the same process as before, by cutting out \([-a, a]\) and then taking the limit \( a \to 0 \).

5 Could we have given a principal value integral value to \( \int_{-1}^1 1/x^2 \, dx \)? If yes, find the value. If not, tell why not.

Lecture 23: Improper integrals

In this lecture, we look at integrals on infinite intervals or where the function can get infinite at some point. These integrals are called improper integrals. The area under the curve can remain finite or become infinite.

1. What is the integral \( \int_{1}^{\infty} \frac{1}{x^2} \, dx \)?

Since the anti-derivative is \(-\frac{1}{x}\), we have

\[
\left. -\frac{1}{x} \right|_{1}^{\infty} = -1/\infty + 1 = 1 .
\]

To justify this, compute the integral \( \int_{b}^{1} \frac{1}{x^2} \, dx = 1 - 1/b \) and see that in the limit \( b \to \infty \), the value 1 is achieved.

In a previous lecture, we have seen a choking example similar to the following one:

2. \[
\int_{-1}^{1} \frac{1}{x^2} \, dx = -\frac{1}{x}|_{-1}^{1} = -1 - 1 = -2 .
\]

This does not make any sense because the function is positive so that the integral should be a positive area. The problem is this time not at the boundary \(-1, 1\). The sore point is \( x = 0 \) over which we have carelessly integrated over.

The next example illustrates the problem with the previous example better:

3. The computation

\[
\int_{0}^{1} \frac{1}{x^2} \, dx = \frac{1}{x}|_{0}^{1} = -1 + \infty .
\]

indicates that the integral does not exist. We can justify by looking at integrals

\[
\int_{a}^{1} \frac{1}{x^2} \, dx = -\frac{1}{x}|_{a}^{1} = -1 + \frac{1}{a}
\]

which are fine for every \( a > 0 \). But this does not converge for \( a \to 0 \).

Do we always have a problem if the function goes to infinity at some point?

4. Find the following integral

\[
\int_{0}^{1} \frac{1}{\sqrt{x}} \, dx .
\]

Solution: Since the point \( x = 0 \) is problematic, we integrate from \( a \) to 1 with positive \( a \) and then take the limit \( a \to 0 \). Since \( x^{-1/2} \) has the antiderivative \( x^{1/2}/(1/2) = 2\sqrt{x} \), we have

\[
\int_{a}^{1} \frac{1}{\sqrt{x}} \, dx = 2\sqrt{x}|_{a}^{1} = 2\sqrt{1} - 2\sqrt{a} = 2(1 - \sqrt{a}) .
\]

There is no problem with taking the limit \( a \to 0 \). The answer is 2. Even so the region is infinite its area is finite. This is an interesting example. Imaging this to be a container for paint. We can fill the container with a finite amount of paint but the wall of the region has infinite length.

5. Evaluate the integral \( \int_{0}^{1} \frac{1}{\sqrt{1 - x^2}} \, dx \). Solution: The antiderivative is \( \arcsin(x) \). In this case, it is not the point \( x = 0 \) which produces the difficulty. It is the point \( x = 1 \). Take \( a > 0 \) and evaluate

\[
\int_{0}^{1-a} \frac{1}{\sqrt{1 - x^2}} \, dx = \arcsin(x)|_{0}^{1-a} = \arcsin(1-a) - \arcsin(0) .
\]

Now \( \arcsin(1-a) \) has no problem at limit \( a \to 0 \). Since \( \arcsin(1) = \pi/2 \) exists. We get therefore the answer \( \arcsin(1) = \pi/2 \).

6. Rotate the graph of \( f(x) = \frac{1}{x} \) around the \( x \)-axes and compute the volume of the solid between 1 and \( \infty \). The cross section area is \( \pi/x^2 \). If we look at the integral from 1 to a fixed \( R \), we get

\[
\int_{1}^{R} \pi \, dx = -\pi|x|_{1}^{R} = -\pi/R + \pi .
\]

This converges for \( R \to \infty \). The volume is \( \pi \). This famous solid is called Gabriels trumpet. This solid is so prominent because if you look at the surface area of the small slice, then it is larger than \( dx/2\pi/x \). The total surface area of the trumpet from 1 to \( R \) is therefore larger than \( \int_{1}^{R} 2\pi/x \, dx = 2\pi(\log(R) - \log(1)) \), which goes to infinity. We can fill the trumpet with a finite amount of paint but we can not paint its surface.
Finally, let’s look at the following example.

Evaluate the integral \( \int_0^\infty \sin(x) \, dx \). **Solution.** There is no problem at the boundary 0 nor at any other point. We have to investigate however, what happens at \( \infty \). Therefore, we look at the integral \( \int_0^b \sin(x) \, dx = -\cos(x)|_0^b = 1 - \cos(b) \). We see that the limit \( b \to \infty \) does not exist. The integral fluctuates between 0 and 2.

The next example leads to a topic in a follow-up course. It is not covered here, but could make you curious:

\(^1\)Hardy, Mathematical Gazette, 5, 98-103, 1909.
Lecture 23: Worksheet

Inproper integrals

1. Find the value of the improper integral
\[ \int_{1}^{\infty} \frac{1}{x^{11}} \, dx \]

2. Find the following improper integral
\[ \int_{0}^{1} \frac{1}{\sqrt{1-x}} \, dx \]

3. We have met the Maria Agnesi function
\[ f(x) = \frac{1}{1+x^2} \]
early in the course already. Evaluate the integral
\[ I = \int_{-\infty}^{\infty} \frac{1}{1+x^2} \, dx \]
The function \( g(x) = \frac{1}{1+x^2} \) is a probability distribution called Cauchy distribution. It is a nonzero function which has the property that \( \int_{-\infty}^{\infty} g(x) \, dx = 1 \).
Lecture 24: Applications of integration

You have seen these integration applications:

- the computation of area
- the computation of volume
- position from acceleration
- cost from marginal cost

Here are some more:

- probabilities and distributions
- averages and expectations
- finding moments of inertia
- work from power

Probability

In probability theory functions are used as observables or to define probabilities.

Assuming our probability space to be the real line, an interval \([a, b]\) is called an event. Given a nonnegative function \(f(x)\) which has the property that \(\int_{-\infty}^{\infty} f(x) \, dx = 1\), we call \(P(A) = \int_{0}^{b} f(x) \, dx\) the probability of the event. The function \(f(x)\) is called the probability density function.

The most famous and most important probability density is the normal distribution:

\[
f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}
\]

It is the distribution which appears most often if data can take both positive and negative values. The reason why it appears so often is that if one observes different unrelated quantities with the same statistical properties, then their sum, suitably normalized becomes the normal distribution. If we measure errors for example, then those errors often have a normal distribution.

1 The probability density function of the exponential distribution is defined as \(f(x) = e^{-x}\) for \(x \geq 0\) and \(f(x) = 0\) for \(x < 0\). It is used to used measure lengths of arrival times like the time until you get the next phone call. The density is zero for negative \(x\) because there is no way we can travel back in time. What is the probability that you get a phone call between times \(x = 1\) and times \(x = 2\) from now? The answer is \(\int_{1}^{2} f(x) \, dx\).

2 For the exponential function the cumulative distribution function is

\[
\int_{-\infty}^{x} f(x) \, dx = \int_{0}^{x} f(x) \, dx = -e^{-x} \bigg|_{0}^{x} = 1 - e^{-x}.
\]

The probability density function \(f(x) = \frac{1}{\sqrt{\pi x}}\) is called the Cauchy distribution.

3 Find its cumulative distribution function. Solution:

\[
F(x) = \int_{-\infty}^{x} f(t) \, dt = \frac{1}{\pi} \arctan(x) \bigg|_{-\infty}^{x} = \left(\frac{1}{\pi} \arctan(x) + \frac{1}{2}\right).
\]

Average

Here is an example for computing the average.

4 Assume the level in a honey jar over \([0, 2\pi]\) containing crystallized honey is given by a function \(f(x) = 3 + \sin(3x)/5 + x(2\pi - x)/10\). In order to restore the honey, it is placed into hot water. The honey melts to its normal state. What height does it have? Solution: The average height is \(\int_{0}^{2\pi} f(x) \, dx/(2\pi)\) which is the area divided by the base length.

In probability theory we would call \(f(x)\) a random variable and the average of \(f\) with \(E[f]\) the expectation.
Moment of inertia

If we spin a wire of radius $L$ of mass density $f(x)$ around an axes, the moment of inertia is defined as $I = \int_0^L x^2 f(x) \, dx$.

The significance is that if we spin it with angular velocity $w$, then the energy is $Iw/2$.

Assume a wire has density $1 + x$ and length 3. Find its moment of inertia. **Solution:**

Flywheels have a comeback for powerplants to absorb energy. If there is not enough power, the flywheels are charged, in peak times, the energy is recovered. They work with 80 percent efficiency. Assume a flywheel is a cylinder of radius 1, density 1 and height 1, then the moment of inertia integral is $\int_0^1 z^2 f(z) \, dz$, where $f(z)$ is the mass in distance $z$.

Work from power

If $P(t)$ is the amount of power produced at time $t$, then $\int_0^T P(t) \, dt$ is the work=energy produced in the time interval $[0, T]$.

Energy is the anti-derivative of power.

Assume a power plant produces power $P(t) = 1000 + \exp(-t) + t^2 - t$. What is the energy produced from $t = 1$ to $t = 10$? **Solution.**

Wouldn’t be nice to have one of those bikes with interactive training environments in the gym, allowing to ride in the Peruvian or Swiss Mountains, the California coast or in the Italian Tuscany?

Additionally, there should be some computer game features, racing other riders through beaches, deserts or Texan highways (could be on google earth). Training would be so much more entertaining. Business opportunities everywhere. The first offering such training equipment will make a fortune. Until then we are stuck with TV programs which really suck.

Homework

1 The probability distribution which describes the time you have to wait for your next email is $f(x) = 3e^{-3x}$. What is the probability that you get your next email in the next 2 hours, that is between $x = 0$ and $x = 2$?

2 Assume the probability distribution for the waiting time to the next warm day is $f(x) = (1/4)e^{-x/4}$, where $x$ has days as unit. What is the probability to get a warm day between tomorrow and after tomorrow that is between $x = 1$ and $x = 2$?

3 A rod modeled over the interval $[0, 4]$ has temperature $f(x) = 5 + x^2 - 3x$ at position $x$. Find the average temperature.

4 A CD Rom has radius 6. If we would place the material at radius $x$ onto one point, we get a density of $f(x) = 2\pi x$. Find the moment of inertia $I$ of the disc. If we spin it with an angular velocity of $w = 20$ rounds per second. Find the energy $E = Iw^2/2$.

5 a) You are on a stationary bike in the Hemenway gym and pedal with power $P(t) = 200 + 100\sin(10\pi t) - \frac{t}{300} + \frac{t^2}{19440}$ (in Watts=W). The periodic fluctuations come from a hilly route. The linear term is the "tiring effect" and the quadratic term is due to endorphins kicking in eventually. What energy (Joules J=W s) have you produced in the time $t \in [0, 1800]$ (s=seconds)?

b) Since we do math not physics, we usually ignore all the units but this one is just too much fun. If you divide the result by 4184, you get kilo calories = food calories. Eating an apple gives you about 80 food calories. How many apples can you eat after your half hour workout, just to get even?
Lecture 24: Worksheet

Applications of integration

1. Find the cumulative distribution function

   \[ F(x) = \int_{-\infty}^{x} f(t) \, dt \]

   of the exponential distribution in the case \( f(x) = 2 \exp(-2x) \).

2. Find the moment of inertia of a rod which has density \( f(x) = x \)
   and length 10.

   \[ \int_{0}^{L} x^2 f(x) \, dx \]

3. A light bulb produces 100W. How much energy in kw/Hours does it use in 1 year? Assume you pay 10 cents for each kW/h. How much does it cost?
Lecture 25: Related rates

Before we continue with integration, we include a short flash-back on differentiation. This allows us to solidify the chain rule

\[ \frac{d}{dx} f(g(x)) = f'(g(x))g'(x) \]

which will be very useful for the integration technique called "substitution". Since the chain rule is often perceived as a difficult concept in calculus, it is good to come back to it again. We take the opportunity also to review a bit our differentiation skills and to take some fresh breath before launching into more advanced integration techniques.

1. Assume we inflate a balloon and pump 5 volume units per unit time into it. If the balloon has radius 7, what is the rate of change of the radius? Solution. Let \( V(r) \) be the volume and \( r(t) \) the radius at time \( t \). Since \[ V(r(t)) = \frac{4\pi r(t)^3}{3} \] we have by the chain rule

\[ 5 = \frac{dV}{dt}(r(t)) = 4\pi r(t)^2 \frac{dr}{dt} \]

This relation allows us to compute \( \frac{dr}{dt} = 5/(4\pi r^2) = 5/(4\pi 7^2) \).

2. Hydrophilic water gel spheres made from polyacrylamide polymer can expand 300 times their original size as you see in class. Assume they have initially a diameter of 1 cm and that they expand in 10 hours to its 300 fold volume. Find the rate of change of the radius in time when they have a volume of 100 (cm\(^3\)). Solution. We have the same rule \[ V = \frac{4\pi r^3}{3} \]. The problem gives us \( d/dt V(r(t)) = 300/10 = 30. \) The rest is now the same as in the previous problem: \( 30 = 4\pi r^2 \frac{dr}{dt} \). Since \( r = 100 \) we get \( \frac{dr}{dt} = 30/(4\pi 100^2) \).

3. The upper part of a wine glass has a shape \( y = x^2 \) with \( 0 \leq y \leq 2 \). We assume the glass is half full, meaning that the wine level is at \( y = 1 \). We taste the wine with 1 ml/sec using a straw, ignoring any political and behavioral correctness. How fast does the wine level sink at that moment?

Solution: The area of the wine layer at height \( y \) is \( A(y) = x^2 \pi \), \( y \pi \). The volume is \[ V(y) = \int_0^y x^2 \pi \, dy = y^2 \pi /2 \] We know

\[ -1 = \frac{dV}{dy}(y(t)) = V'(y) \frac{dy}{dt} = \pi y y'(t) \]

so that \( y'(t) = -1/(\pi y) \) and for \( y = 1 \) this is \(-1/\pi\).

4. A person of height 6 feet is located at \( x = 6 \) and walks with constant speed 1. A lamp at \( x = 0 \) is at height 10 feet. With what speed does the shadow of the person proceed on the floor? Solution: If the person is at position \( x \), the shadow’s length \( L \) satisfies \[ \frac{L}{6} = (L + x)/10 \] which is \( L = 9 \). The relation \( L/6 = (L + x)/10 \) means \( L = 3x/2 \) so that \( L'/3x'/2 = 3/2 \).

5. Romeo and Juliet have meet secretly at position \((0, 0)\) and rush home. Romeo runs with speed 4 meters/seconds to the east. Assume their distance satisfies \( l(t) = t^4 \). After 10 seconds, they wave back to each other. With what speed does Juliet run at this time? Solution. What do we know? \( x(t) = 4t \) is the position of Romeo and \( l(t) = t^4 \). If \( y(t) \) is the \( y \) position of Juliet, the law we use is Pythagoras \( l^2 = x^2 + y^2 \) so that \( y(t) = \sqrt{l^2 - x^2} \) and \( y(10) = \sqrt{1000 - 100} = \sqrt{900} = 30 \). Now differentiate the law to get \( 2l' = 2xx' + 2yy' \). We know all quantities at time \( t = 10 \); we know \( l = 1000, l' = 300, x = 40, x' = 4, y = 30 \) and compute \( y' = (2000 * 300 - 80 * 4)/60 = 29984/3 \).

Solution: What do we know? \( x(t) = 4t \) is the position of Romeo and \( l(t) = t^4 \). If \( y(t) \) is the \( y \) position of Juliet, the law we use is Pythagoras \( l^2 = x^2 + y^2 \) so that \( y(t) = \sqrt{l^2 - x^2} \) and \( y(10) = \sqrt{1000 - 100} = \sqrt{900} = 30 \). Now differentiate the law to get \( 2l' = 2xx' + 2yy' \). We know all quantities at time \( t = 10 \); we know \( l = 1000, l' = 300, x = 40, x' = 4, y = 30 \) and compute \( y' = (2000 * 300 - 80 * 4)/60 = 29984/3 \).
A ladder has length 1. Assume it slips on the ground away with constant speed 2 in the x-direction. What is the speed of the top part of the ladder sliding down the wall at the time when \( x = y \)? Solution We know \( x'(t) = 2 \) and that \( x(t), y(t) \) are related by \( x^2(t) + y^2(t) = 1 \). Differentiation gives \( 2x(t)x'(t) + 2y(t)y'(t) = 0 \). We get \( y'(t) = -\frac{x'}{y} \). At \( x = 1 \), we have \( x' = 2 \). What is \( y' \)?

A kid slides down a slide of the shape \( y = 2x \). Assume at height \( y = 2 \) we have \( dy/dt = -7 \). What is \( dx/dt \)? Solution: differentiate the relation to get \( y' = -2x/x^2 \). At \( y = 2 \) we have \( x = 1 \). Now solve for \( x' \) to get \( x' = -y/x^2/2 = -7/2 \).

A canister of oil releases oil at a constant rate 5. With what rate does the radius of the oil spill increase, when the radius is 1? Solution. We have \( A(r) = \pi r^2 \) and so \( 5 = A'(r) = 2\pi r' \). Solving for \( r' \) gives \( r' = 5/(2\pi) \) which is \( 5/(2\pi) \).

Related rates problems link quantities by a rule. These quantities can depend on time. To solve a related rates problem, differentiate the rule with respect to time and solve for the unknown quantity.

Related rates problems are not so easy. The difficulty comes from the fact that they are often "word problems" which first have to be parsed. We have to find the rule and differentiate it. In all the problems on this handout, the rule is boxed. It is important to understand which variables depend on time. If a term \( x^3 \) appears for example and \( x \) depends on time, then \( d/dt x^3 = 3x^2 x' \).

**Homework**

1. The ideal gas law \( \rho V = T \) relates pressure \( p \) and volume \( V \) and temperature \( T \). Assume the temperature \( T = 50 \) is fixed and the volume is at \( V = 2 \) and decreased by \( V' = -3 \). Find the rate \( \rho' \) with which the pressure increases.

2. Assume the total production rate \( P \) of a new tablet computer product for kids is constant 100 and given by the famous Cobb-Douglas formula \( P = L^{1/3} K^{2/3} \) where \( L = 64 \) is the labor and \( K = 125 \) is the cost. Assume labor is increased at a rate \( L' = 2 \). What is the cost change \( K' \)?

3. You observe an airplane at height \( h = 10000 \) meters directly above you and see that it moves with rate \( \phi' = 5 \) degree per second (which is \( 5\pi/180 \) radians per second). What is the speed \( x' \) of the airplane directly above you where \( x = 0 \)? Hint: Use \( \tan(\phi) = x/h \) and make a picture to figure out what \( \phi \) is.

4. An isosceles triangle with base \( 2a \) and height \( h \) has fixed area \( A = \frac{a}{2}h \). Assume the height is decreased by a rate \( h' = -2 \). With what rate does \( a \) increase if \( h = 1/2 \)?

5. There are cosmological models which see our universe as a four dimensional sphere which expands in space time. Assume the volume \( V = \frac{4}{3}\pi r^3/2 \) increases at a rate \( d/dt V(r(t)) = 100\pi r^2 \). What is \( r' \) if the current radius is \( r = 47 \) (billion light years).
Lecture 25: Worksheet

Related rates

1. An underwater oil spill releases oil at the constant amount. The area $A(r)$ of the oil increases with $A'(r(t)) = 2$. If the radius is $r = 4$, what is the rate of change of $r$?

2. The resistance $R$, voltage $U$ and current $I$ are related by $U = RI$.

Assume the temperature increases, the resistance $R(t)$ increases by a constant amount $R' = 2$. If the voltage stays constant $U = 4$ what is the rate of change of $I$?
Lecture 26: Implicit differentiation

We have seen an implicit differentiation example in the Valentines day lecture and will repeat this topic more. Implicit differentiation is also crucial to find the derivative of inverse functions. We will review this here because this will give us handy tools for integration.

The chain rule, related rates and implicit differentiation are all the same concept, but viewed from different angles. You can see implicit differentiation as a special case of related rates where one of the quantities is “time” meaning that this is the variable with respect to which we differentiate.

1 Points \((x, y)\) in the plane which satisfy \(x^2 + 9y^2 = 10\) form an ellipse. Find the slope of the tangent line at the point \((1, 1)\).

Solution: We want to know the derivative \(dy/dx\). We have \(2x + 18yy' = 0\). Using \(x = 1, y = 1\) we see \(y' = -2x/(18y) = -1/9\).

Remark. We could have looked at this as a related rates problem where \(x(t), y(t)\) are related and \(x' = 1\) Now \(2xx' + 9 \cdot 2yy' = 0\) allows to solve for \(y' = -2x'/9y) = -2/9\).

2 The points \((x, y)\) which satisfy the equation \(x^4 - 3x^2 + y^2 = 0\) forms a figure 8 called lemniscate of Gerono. It contains the point \((1, \sqrt{2})\). Find the slope of the curve at that point. Solution: We differentiate the law describing the curve with respect to \(x\). This gives

\[5x^3 - 6x + 2yy' = 0\]

We can now solve for \(y' = (6x - 5x^3)/(2y) = 1/2\).

3 The Valentine equation \((x^2 + y^2 - 1)^3 - x^2y^3 = 0\) contains the point \((1, 1)\). Near \((1, 1)\), we have \(y = y(x)\) so that \((x^2 + y(x)^2 - 1)^3 - x^2y(x)^3 = 0\). Find \(y'\) at the point \(x = 1\).

Solution Take the derivative

\[0 = 3(x^2 + y^3 - 1)(2x + 2yy') - 2xy^3 - 3x^2y^2y'(x)\]

and solve for

\[y' = -\frac{3(x^2 + y^3 - 1)2x - 2xy^3}{3(x^2 + y^3 - 1)2y - 3x^2y^2}.

For \(x = 1, y = 1\), we get \(-4/3\).

4 The energy of a pendulum with angle \(x\) and angular velocity \(y\) is

\[y^2 - \cos(x) = 1\]

is constant. What is \(y'\)? We could solve for \(y\) and then differentiate. Simpler is to differentiate directly and get \(yy' + \sin(x) = 0\) so that \(y' = -\sin(x)/y\). At the point \((\pi/2, 1)\) for example we have \(y' = -1\).
What is the difference between related rates and implicit differentiation?

Implicit differentiation is the special case of related rates where one of the variables is time.

**Derivatives of inverse functions**

Implicit differentiation has an important application: it allows to compute the derivatives of inverse functions. It is good that we review this, because we can use these derivatives to find anti-derivatives.

5 Find the derivative of \( \log(x) \) by differentiating \( \exp(\log(x)) = x \).

**Solution:**

\[
1 = \frac{d}{dx} \frac{d}{dx} \exp(\log(x)) = \exp(\log(x)) \frac{d}{dx} \frac{d}{dx} \log(x) = x \log'(x).
\]

Solve for \( \log'(x) = 1/x \). Since the derivative of \( \log(x) \) is \( 1/x \). The anti-derivative of \( 1/x \) is \( \log(x) + C \).

6 Find the derivative of \( \arccos(x) \) by differentiating \( \cos(\arccos(x)) = x \).

**Solution:**

\[
1 = \frac{d}{dx} \frac{d}{dx} \cos(\arccos(x)) = -\sin(\arccos(x)) \frac{d}{dx} \arccos'(x) = -\sqrt{1 - x^2} \arccos'(x) = -\sqrt{1 - x^2} \frac{d}{dx} \arccos'(x).
\]

Solving for \( \arccos'(x) = -1/\sqrt{1 - x^2} \). The anti-derivative of \( \arccos(x) \) is \( -1/\sqrt{1 - x^2} \).

7 Find the derivative of \( \arctan(x) \) by differentiating \( \tan(\arctan(x)) = x \).

**Solution:** This is a derivative which we have seen several times by now. We use the identity \( 1/\cos^2(x) - \tan^2(x) + 1 \) to get

\[
1 = \frac{d}{dx} \frac{d}{dx} \tan(\arctan(x)) = \frac{d}{dx} \frac{d}{dx} \arctan'(x) = \frac{1}{\cos^2(x)} \arctan'(x) = (1 + \tan^2(\arctan(x))) \arctan'(x).
\]

Solve for \( \arctan'(x) = 1/(1 + x^2) \). The anti-derivative of \( \arctan(x) \) is \( 1/(1 + x^2) \).

8 Find the derivative of \( f(x) = \sqrt{x} \) by differentiating \( (\sqrt{x})^2 = x \).

**Solution:**

\[
1 = \frac{d}{dx} \frac{d}{dx} (\sqrt{x}) = \frac{d}{dx} 2\sqrt{x} = 2\sqrt{x} f'(x)
\]

so that \( f'(x) = 1/(2\sqrt{x}) \).

**Homework**

1 The equation \( y^2 = x^2 - x \) defines the graph of the function \( f(x) = \sqrt{x^2 - x} \). Find the slope of the graph at \( x = 2 \) directly by differentiating \( f \). Then use the implicit differentiation method and differentiate \( y^2 = x^2 - x \) assuming \( y(x) \) is a function of \( x \) and solving for \( y' \).

2 The equation \( x^2 + y^2 = 5 \) defines a circle. Find the slope of the tangent at \((1, 2)\).

3 The equation \( x^{100} + y^{100} = 1 + 2^{100} \) defines a curve which looks close to a square. Find the slope of the curve at \((2, 1)\).

4 Derive again the derivative of \( \arccot(x) \) as we did before in this course and also during the first midterm.

5 a) The relation \( \sin(x - y) - 2 \cos((\pi/2)xy) = 0 \) relates \( x(t) \) and \( y(t) \). Assume \( x' = 1 \) at \((1, 1)\) what is \( y' \)? This is a related rates problem.

b) Now do it directly. Since \( x' = 1 \) we can use \( x \) as the variable. Find \( y'(x) \) by implicit differentiation. You should get the same result as in a).
Lecture 26: April First Worksheet

Implicit differentiation

1. Find the slope of $y'(x)$ if $2x^3 - y^3 = y$ at the point $(1, 1)$.

2. Find the derivative of $y(x) = x^{1/5}$ by differentiating $y^5 = x$.

3. The equation $y = x$ relates two quantities and defines $y$ in terms of $x$. Assume $x = 2$ find $\frac{dy}{dx}$.

Hint. This problem tries hard to be a April first joke but does not quite succeed.
Lecture 27: Review for second midterm

Major points

The intermediate value theorem assures that there is \( x \in (a, b) \) with \( f'(x) = (f(b) - f(a))/(b - a) \). A special case is Rolle’s theorem, where \( f(b) = f(a) \).

Catastrophes are parameter values where a local minimum disappears. Typically the system jumps then to a lower minimum.

Definite integrals \( F(x) = \int_a^b f(x) \, dx \) are defined as a limit of Riemann sums \( \int_a^b f(x) \, dx \).

A function \( F(x) \) satisfying \( F' = f \) is called the anti-derivative of \( f \). The general anti-derivative is \( F + C \) where \( C \) is a constant.

The fundamental theorem of calculus tells \( d/dx \int_a^b f(x) \, dx = f(x) \) and \( \int_a^b f'(x) \, dx = f(x) - f(0) \).

The integral \( \int_a^b g(x) - f(x) \, dx \) is the signed area between the graphs of \( f \) and \( g \). Places, where \( f < g \) are counted negative.

The integral \( \int_a^b A(x) \, dx \) is a volume if \( A(x) \) is the area of a slice of the solid perpendicular to a point \( x \) on an axes.

Write improper integrals as limits of definite integrals \( \int_a^b f(x) \, dx = \lim_{n \to \infty} \int_a^b f(x) \, dx \). We similarly treat points, where \( f \) is discontinuous.

Besides area, volume, total cost, or position, we can compute averages, inertia or work using integrals.

If \( x, y \) are related by \( F(x(t), y(t)) = 0 \) and \( x(t) \) is known we can compute \( y'(t) \) using the chain rule. This is related rates.

If \( f(g(t)) \) is known we can compute \( g'(x) \) using the chain rule. This works for inverse functions. This is implicit differentiation.

To determine the catastrophes for a family \( f_a(x) \) of functions, determine the critical points in dependence of \( c \) and find values \( c \), where a critical point changes from a local minimum to a local maximum.

---

Important integrals

\[
\begin{align*}
\cos(x) & \quad \sin(x) \\
-\cos(x) & \quad \exp(x) \\
\tan(x) & \quad 1/\cos^2(x) \\
1/(1 + x^2) & \quad \arctan(x) \\
1/\sqrt{1 - x^2} & \quad \arcsin(x)
\end{align*}
\]

Improper integrals

\[
\begin{align*}
\int_0^\infty 1/x^2 \, dx & \quad \text{Prototype of first type improper integral which exists.} \\
\int_0^\infty 1/x \, dx & \quad \text{Prototype of first type improper integral which does not exist.} \\
\int_0^1 1/x \, dx & \quad \text{Prototype of second type improper integral which does not exist.} \\
\int_0^1 1/\sqrt{x} \, dx & \quad \text{Prototype of second type improper integral which does exist.}
\end{align*}
\]

The fundamental theorem

\[
\frac{d}{dx} \int_a^b f(x) \, dx = f(x)
\]

\[
\int_a^b f'(x) \, dx = f(x) - f(0).
\]

This implies

\[
\int_a^b f'(x) \, dx = f(b) - f(a)
\]

Without limits of integration, we call \( \int f(x) \, dx \) the anti derivative. It is defined up to a constant. For example \( \int \sin(x) \, dx = -\cos(x) + C \).

Applications

Calculus applies directly if there are situations where one quantity is the derivative of the other.

Tricks

Whenever dealing with an area or volume computation, make a picture.

In related rates problems, make sure you understand what are variables and what are constants.

For volume computations, find the area of the cross section \( A(x) \) and integrate.

For area computations find the length of the slice \( f(x) \) and integrate.
Lecture 27: Review Problems

Definite integral

1 The following integral defines the area of a region. Draw it:
\[ \int_{\pi/2}^{\pi} x - \sin(x) \, dx . \]

Catastrophes

2 Let’s look at the family of functions \( f_c(x) = x^5 + cx^3 \). You see three graphs. They display the function for \( c = -1 \), \( c = 0 \) and \( c = 1 \). What can you say about catastrophes?

Volumes

4 If we rotate the witch of Agnesi \( y = (1 + x^2)^{-1} \) around the \( x \) axes, we obtain a solid. Find its volume. Hint. To find the integral, compute the derivative of \( x/(1 + x^2) \) and get inspired.

Related Rates

5 The curve \( x^2 - y^2 = 3y \) is an example of a hyperbola. If \( x(t) = 2 + t \). Find the related rate \( y' \) near \( (2,1) \).
Lecture 28: Substitution

If we differentiate the function \(\sin(x^2)\) and use the chain rule, we get \(\cos(x^2)2x\). By the fundamental theorem of calculus, the anti derivative of \(\cos(x^2)2x\) is \(\sin(x^2)\). We know therefore

\[
\int \cos(x^2)2x \, dx = \sin(x^2) + C .
\]

Spotting the chain rule

How can we see the integral without knowing the result already? Here is a very important case:

If we can spot that \(f(x) = g(u(x))u'(x)\), then the anti derivative of \(f\) is \(G(u(x))\) where \(G\) is the anti derivative of \(g\).

1. Find the anti derivative of \(e^{x^2+x}(4x^3+2x)\).

Solution: The derivative of the inner function is to the right.

2. Find \(\int \sqrt{x^2+1} \, dx\). Solution: \((x+1)^{3/2}(2/3)\).

3. Find \(\int \frac{1}{1+(5x+2)^2} \, dx\). Solution: \(\arctan(5x+2)(1/5)\).

Doing substitution

Spotting things is sometimes not easy. The method of substitution helps to formalize this. To do so, identify a part of the formula to integrate and call it \(u\) then replace an occurrence of \(u'\, dx\) with \(du\).

\[
\int f(u(x))u'(x) \, dx = \int f(u) \, du .
\]

Here is a more detailed description: replace a prominent part of the function with a new variable \(u\), then use \(du = u'(x)\, dx\) to replace \(dx\) with \(du/u'\). We aim to end up with an integral \(\int g(u) \, du\) which does not involve \(x\) anymore. Finally, after integration of this integral, replace the variable \(u\) again with the function \(u(x)\). The last step is called back-substitution.

4. Find the anti-derivative \(\int \log(\log(x))/x \, dx\).

Solution Replace \(\log(x)\) with \(u\) and replace \(u'\, dx = 1/xdx\) with \(du\). This gives \(\int \log(u) \, du = u \log(u) - u = \log(x) \log(\log(x)) - \log(x)\).

5. Solve the integral \(\int x/(1+x^4) \, dx\).

Solution Substitute \(u = x^2, du = 2x \, dx\) to get \((1/2) \int du/(1+u^2) = (1/2) \arctan(u) = (1/2) \arctan(x^2)\).

6. Find the anti derivative \(\int \cos(\sqrt{x})/\sqrt{x} \, dx\).

Solution: \(u = \sqrt{x}, du = 1/2 \, dx\) and \(\int du/(1+u^2) = (1/2) \arctan(u) = (1/2) \arctan(x^2)\).

Here are some examples which are not so straightforward:

7. Find \(\int f(ax+b) \, dx\) where \(F\) is the anti derivative of \(f\).
Solve the integral $\int u \, du$.

a) Find the indefinite integral $\int x \, du$.

b) Find the definite integral $\int (x^2 - 1)^2 + 1 \, du$.

c) Find the antiderivative of $\int \sqrt{x^2 + 1} \, dx$.

\textbf{Solution.} To keep track of which bounds we consider it can help to substitute $u = \sqrt{x^2 + 1}$. This gives $x = u^2 - 1$, $dx = 2udu$ and we get $\int (u^2 - 1)^2 + 1 \, du$. When doing definite integrals, we could find the antiderivative as described and then fill in the boundary points. Substituting the boundaries directly accelerates the process since we do not have to substitute back to the original variables.

\textbf{Definite integrals}

When doing definite integrals, we could find the antiderivative as described and then fill in the boundary points. Substituting the boundaries directly accelerates the process since we do not have to substitute back to the original variables:

\begin{align*}
\int_a^b g(u(x))u'(x) \, dx &= \int_{u(a)}^{u(b)} g(u) \, du.
\end{align*}

\textbf{Proof.} This identity follows from the fact that the right hand side is $G(u(b)) - G(u(a))$ by the fundamental theorem of calculus. The integrand on the left has the anti-derivative $G(u(x))$. Again by the fundamental theorem of calculus the integral leads to $G(u(b)) - G(u(a))$.

Top: To keep track which bounds we consider it can help to write $\int_{x=a}^{x=b} f(x) \, dx$.

13 Find the anti derivative of $\int_{x=0}^{x=2} \sin(x^3 - 1)x^2 \, dx$. \textbf{Solution.}

\begin{align*}
\int_{x=0}^{x=2} \sin(x^3 - 1)x^2 \, dx &= \\
\text{Solution:} & \text{Use } u = x^3 + 1 \text{ and get } du = 3x^2dx. \text{ We get} \\
\int_{u=1}^{u=7} \sin(u)du/3 & = (1/3) \cos(u)|_1^7 = [-\cos(7) + \cos(1)]/3.
\end{align*}

Also here, we can see the integrals directly

To integrate $f(Ax + B)$ from $a$ to $b$ we get $[F(Ab + B) - F(Aa + B)]/A$, where $F$ is the anti-derivative of $f$.

14 $\int_{x=1}^{x=5} \frac{1}{\log(x)} \, dx = [\log(u)]/5|_1^5 = \log(6)/5.$

15 $\int_{x=0}^{x=5} \exp(4x - 10) \, dx = [\exp(10) - \exp(2)]/4.$
Lecture 28: Worksheet

Substitution

1. \[ \int \sin(2x + 3) \, dx \]

2. \[ \int \frac{1}{(x + 8)^5} \, dx \]

3. \[ \int \frac{\log(5x)}{x} \, dx \]

4. \[ \int \frac{x}{\sqrt{x^2 + 1}} \, dx \]

5. \[ \int \frac{e^x}{(e^x + 5)^2} \, dx \]

Here is a situation, where substitution appears in an application; let's look at the probability density function. The integral

\[ m = \int_{-\infty}^{\infty} xf(x) \, dx \]

is called the **mean** of the distribution.

6. Find the mean of the probability density function

\[ f(x) = \frac{1}{\sqrt{\pi}} e^{-(x-3)^2/2} \].
Lecture 29: Integration by parts

If we integrate the product rule \((uv)' = u'v + uv'\) we obtain an integration rule called integration by parts. It is a powerful tool, which complements substitution. As a rule of thumb, always try first to simplify a function and integrate directly, then give substitution a first shot before trying integration by parts.

\[
\int u(x) v'(x) dx = u(x)v(x) - \int u'(x)v(x) \, dx.
\]

1. Find \(\int x \sin(x) \, dx\). Solution. Let's identify the part which we want to differentiate and call it \(u\) and the part to integrate and call it \(v'\). The integration by parts method now proceeds by writing down \(uv\) and subtracting a new integral which integrates \(u'v\): 
\[
\int x \sin(x) \, dx = x \sin(x) - \int \cos(x) \, dx = x \sin(x) + \cos(x) + C \, dx.
\]

2. Find \(\int xe^x \, dx\). Solution. 
\[
\int xe^x \, dx = x e^x - \int e^x \, dx = xe^x - e^x + C \, dx.
\]

3. Find \(\int \log(x) \, dx\). Solution. There is only one function here, but we can look at it as \(\log(x) \cdot 1\)
\[
\int \log(x) \, dx = \log(x) x - \int \frac{1}{x} \, dx = x \log(x) - x + C.
\]

4. Find \(\int x \log(x) \, dx\). Solution. Since we know from the previous problem how to integrate log we could proceed like this. We would get through but what if we do not know? Let's differentiate \(\log(x)\) and integrate \(x\):
\[
\int \log(x) \, dx = \log(x) \frac{x^2}{2} - \int \frac{1}{2} \frac{x^2}{x} \, dx
\]
which is \(\log(x) x^2/2 - x^2/4\).

We see that it is better to differentiate log first.

5. Marry go round: Find \(I = \int \sin(x) \exp(x) \, dx\). Solution. Let's integrate \(\exp(x)\) and differentiate \(\sin(x)\).
\[
= \sin(x) \exp(x) - \int \cos(x) \exp(x) \, dx.
\]

Let's do it again:
\[
= \sin(x) \exp(x) - \cos(x) \exp(x) - \int \sin(x) \exp(x) \, dx.
\]

We moved in circles and are stuck! Are we really? We have derived an identity
\[
I = \sin(x) \exp(x) - \cos(x) \exp(x) - I
\]
which we can solve for \(I\) and get 
\[
I = (\sin(x) \exp(x) - \cos(x) \exp(x))/2.
\]

Integration by parts can bog you down if you do it several times. Keeping the order of the signs can be daunting. This is why a tabular integration by parts method is so powerful. It has been called “Tic-Tac-Toe” in the movie Stand and deliver. Let's call it Tic-Tac-Toe therefore.

6. Find the anti-derivative of \(x^2 \sin(x)\). Solution:

<table>
<thead>
<tr>
<th>(x^2)</th>
<th>(\sin(x))</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>(-\cos(x))</td>
</tr>
<tr>
<td>0</td>
<td>(\cos(x))</td>
</tr>
</tbody>
</table>

The antiderivative is 
\[-x^2 \cos(x) + 2x \sin(x) + 2 \cos(x) + C\,.

7. Find the anti-derivative of \((x - 1)^3 e^{2x}\). Solution:

<table>
<thead>
<tr>
<th>((x - 1)^3)</th>
<th>(e^{2x})</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>(e^{2x}/2)</td>
</tr>
<tr>
<td>6</td>
<td>(e^{2x}/4)</td>
</tr>
<tr>
<td>0</td>
<td>(e^{2x}/16)</td>
</tr>
</tbody>
</table>

The anti-derivative is 
\[(x - 1)^3 e^{2x}/2 - 3(x - 1)^2 e^{2x}/4 + 6(x - 1) e^{2x}/8 - 6 e^{2x}/16 + C\,.

8. Find the anti-derivative of \(x^2 \cos(x)\). Solution:

<table>
<thead>
<tr>
<th>(x^2)</th>
<th>(\cos(x))</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>(-\sin(x))</td>
</tr>
<tr>
<td>0</td>
<td>(-\cos(x))</td>
</tr>
</tbody>
</table>

The anti-derivative is 
\[x^2 \sin(x) + 2x \cos(x) - 2 \sin(x) + C\,.

Ok, we are now ready for more extreme stuff.
Find the anti-derivative of $x^7 \cos(x)$. \textbf{Solution:}

<table>
<thead>
<tr>
<th>$x^7$</th>
<th>$\cos(x)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$7x^6$</td>
<td>$\sin(x)$</td>
</tr>
<tr>
<td>$42x^5$</td>
<td>$-\cos(x)$</td>
</tr>
<tr>
<td>$120x^4$</td>
<td>$-\sin(x)$</td>
</tr>
<tr>
<td>$840x^3$</td>
<td>$\cos(x)$</td>
</tr>
<tr>
<td>$2520x^2$</td>
<td>$\sin(x)$</td>
</tr>
<tr>
<td>$5040x$</td>
<td>$-\cos(x)$</td>
</tr>
<tr>
<td>$5040$</td>
<td>$-\sin(x)$</td>
</tr>
<tr>
<td>$0$</td>
<td>$\cos(x)$</td>
</tr>
</tbody>
</table>

The anti-derivative is

$$F(x) = x^7 \sin(x) + 7x^6 \cos(x) - 42x^5 \sin(x) - 210x^4 \cos(x) + 840x^3 \sin(x) + 2520x^2 \cos(x) - 5040x \sin(x) - 5040 \cos(x) + C.$$

Do this without this method and you see the value of the method.

I myself learned the method from the movie "Stand and Deliver", where Jaime Escalante of the Garfield High School in LA uses the method. It can be traced down to an article of V.N. Murty. The method realizes in a clever way an iterated integration by parts method:

$$\int fg' \, dx = fg^{(-1)} - f^{(1)}g^{(-2)} + f^{(2)}g^{(-3)} - \ldots - (-1)^n \int f^{(n+1)}g^{(-n-1)} \, dx$$

which can easily shown to be true by induction and justifies the method: the $f$ function is differentiated again and again and the $g$ function is integrated again and again. You see, where the alternating minus signs come from. You see that we always pair a $k$'th derivative with a $k+1$'th integral and take the sign $(-1)^k$.

When doing integration by parts, We want to try first to differentiate Logs, Inverse trig functions, Powers, Trig functions and Exponentials. This can be remembered as LIPTE which is close to "lipton" (the tea).

For coffee lovers, there is an equivalent one: Logs, Inverse trig functions, Algebraic functions, Trig functions and Exponentials which can be remembered as LIATE which is close to "latte" (the coffee).

Whether you prefer to remember it as a "coffee latte" or a "lipton tea" is up to you.

There is even a better method, the "opportunistic method":

Just integrate what you can integrate and differentiate the rest.

An don’t forget to consider integrating 1, if nothing else works.

Coffee or Tea?

Lecture 30: Numerical integration

Before covering two more integration techniques, we briefly look at some numerical techniques. There are variations of basic Riemann sums but speed up the computation.

Riemann sum with nonuniform spacing

A more general Riemann sum is obtained by choosing \( n \) points in \([a, b]\) and defining
\[
S_n = \sum_{j=0}^{n} f(y_j)(x_{j+1} - x_j) = \sum_{j=0}^{n} f(y_j)\Delta x_j
\]
where \( y_j \) is in \((x_j, x_{j+1})\).

This generalization allows to use a small mesh size where the function fluctuates a lot.

The sum \( \sum f(x_j)\Delta x_j \) is called the left Riemann sum, the sum \( \sum f(x_{j+1})\Delta x_j \) the right Riemann sum.

If \( x_0 = a, x_n = b \) and \( \max_j \Delta x_j \to 0 \) for \( n \to \infty \) then \( S_n \) converges to \( \int_a^b f(x) \, dx \).

1. If \( x_j - x_{j-1} = 1/n \) and \( z_j = x_j \), then we have the Riemann sum as we defined it earlier.
2. You numerically integrate \( \sin(x) \) on \([0, \pi/2]\) with a Riemann sum. What is better, the left Riemann sum or the right Riemann sum? Look also at the interval \([\pi/2, \pi]\)? Solution: you see that in the first case, the left Riemann sum is smaller than the actual integral. In the second case, the left Riemann sum is larger than the actual integral.

Trapezoid rule

The average between the left and right hand Riemann sum is called the Trapezoid rule. Geometrically, it sums up areas of trapezoids instead of rectangles.

The Trapezoid rule does not change things much in the case of equal spacing \( x_k = a + (b-a)k/n \).

\[
\frac{1}{2n} [f(x_0) + f(x_n)] + \frac{1}{n} \sum_{k=1}^{n-1} f(x_k).
\]

Simpson rule

The Simpson rule computes the sum
\[
S_n = \frac{1}{6n} \sum_{k=1}^{n} [f(x_k) + 4f(y_k) + f(x_{k+1})],
\]
where \( y_k \) are the midpoints between \( x_k \) and \( x_{k+1} \). The Simpson rule is good because it is exact for quadratic functions: you can check for \( f(x) = ax^2 + bx + c \) that the formula
\[
\frac{1}{v-u} \int_v^u f(x) \, dx = [f(u) + 4f((u + v)/2) + f(v)]/6
\]
holds. To prove it just run the following two lines in Mathematica: (= means "is equal")

\[
\begin{align*}
[f[\{x\}]] &:= a \, x^2 + b \, x + c; \\
Simplify[[f[u] + f[v] + 4f[(u+v)/2]]/6 == Integrate[f[x], \{x,u,v\}] / (v-u)]
\end{align*}
\]

This actually will imply (as you will see in Math 1b) that the numerical integration for functions which are 4 times differentiable gives numerical results which are \( n^{-4} \) close to the actual integral. For 100 division points, this can give accuracy to \( 10^{-8} \) already.

There are other variants which are a bit better but need more function values. If \( x_k, y_k, z_k, x_{k+1} \) are equally spaced, then

The Simpson 3/8 rule computes
\[
\frac{1}{8n} \sum_{k=1}^{n} [f(x_k) + 3f(y_k) + 3f(z_k) + f(x_{k+1})].
\]

This formula is again exact for quadratic functions: for \( f(x) = ax^2 + bx + c \), the formula
\[
\frac{1}{v-u} \int_v^u f(x) \, dx = [f(u) + 3f((2u+v)/3) + 3f((u+2v)/3) + f(v)]/6
\]
holds. If you are interested, run the two Mathematica lines:

\[
\begin{align*}
[f[\{x\}]] &:= a \, x^2 + b \, x + c; \\
L=Integrate[f[x], \{x,u,v\}] / (v-u); \\
Simplify[[f[u] + f[v] + 3f[(2u+v)/3] + 3f[(u+2v)/3]] / 8 == L]
\end{align*}
\]

This 3/8 method can be slightly better than the first Simpson rule.
Mean value method

The mean value theorem shows that for \( x_k = k/n \), there are points \( y_k \in [x_k, x_{k+1}] \) such that \( f(y_k) = F'(y_k) = \frac{1}{n} \sum_{k=1}^{n} f(x_k) \). This is a version of the fundamental theorem of calculus which is exact in the sense that for every \( n \), this is a correct formula. Let's call \( y_k \) the Rolle points.

For any partition \( x_k \) on \([a, b]\) with \( x_0 = a, x_n = b \), there is a choice of Rolle points \( y_k \in [x_k, x_{k+1}] \) such that the Riemann sum \( \sum_k f(y_k) \Delta(x)_k \) is equal to \( \int_a^b f(x) \, dx \).

For linear functions the Rolle points are the midpoints. In general, the deviation from the midpoint is small if the interval is \([x_0 - t, x_0 + t]\). One can estimate \( g(t) \) to be of the order \( e^{-t^2/6} \). We could modify the trapezoid rule and replace the line through the points by a Taylor polynomial. The Rolle point method is useful for functions which can have poles.

Monte Carlo Method

A powerful integration method is to choose \( n \) random points \( x_k \) in \([a, b]\) and look at the sum divided by \( n \). Because it uses randomness, it is called the Monte Carlo method.

The Monte Carlo integral is the limit \( S_n \) to infinity

\[
S_n = \frac{1}{n} \sum_{k=1}^{n} f(x_k),
\]

where \( x_k \) are \( n \) random values in \([a, b]\).

The law of large numbers in probability shows that the Monte Carlo integral is equivalent to the Lebesgue integral which is more powerful than the Riemann integral. Monte Carlo integration is interesting especially if the function is complicated.

3. Let's look at the salt and pepper function

\[
f(x) = \begin{cases} 
1 & x \text{ rational} \\
0 & x \text{ irrational}
\end{cases}
\]

The Riemann integral with equal spacing \( k/n \) is equal to 1 for every \( n \). But this is only because we have evaluated the function at rational points, where it is 1. The Monte Carlo integral gives zero because if we chose a random number in \([0, 1]\) we hit an irrational number with probability 1.

Homework

1. Use a computer to generate 20 random numbers \( x_k \) in \([0, 1]\). Sum up the square \( x_k^2 \) of these numbers and divide by 20. Compare your result with \( \int_0^1 x^2 \, dx \).
   
   Remark. If using a program, increase the value of \( n \) as large as you can. Here is a Mathematica code:

   \[
   n=20; \text{Sum}[	ext{Random[]}^2,\{n\}]/n
   \]

   Here is an implementation in Perl. It's still possible to cram the code into one line:

   ```perl
   #!/usr/bin/perl
   $n=20; $s=0; for ($i=0; $i<$n; $i++) {$f=exp(rand()); $s+=$f; $f; } print $s/$n;
   ```

2. a) Use the Simpson rule to compute \( \int_0^1 \sin(x) \, dx \) using \( n = 2 \) intervals \([0, \pi/2]\) and \([\pi/2, \pi]\). On each of these intervals \([a, b]\) compute the Simpson sum \( f(a) + 4f((a+b)/2) + f(b)/6 \) with \( f(x) = \sin(x) \). Compare with the actual integral.
   
   b) Now use the \( 3/8 \) Simpson rule to estimate \( \int_0^1 f(x) \, dx \) using \( n = 1 \) intervals \([0, \pi]\). Again compare with the actual integral.

   Instead of adding more numerical methods exercises, we want to practice a bit more integration. The challenge in the following problems is to find out which integration method is best suited. This is good preparation for the final, where we will not reveal which integration method is the best.

3. Integrate \( \tan(x)/\cos(x) \) from 0 to \( \pi/6 \).
4. Find the antiderivative of \( x \sin(x) \exp(x) \).
5. Find the antiderivative of \( x/\sin(x)^2 \).
Lecture 30: Worksheet

Numerical methods

A paraglider starts a flight in the mountain. The velocity is given in the above graph. Find out, whether the paraglider lands lower or higher than where it started.

Hint: To estimate integrals take the average of the number $A$ of squares entirely below the graph and the number $B$ of squares containing part of the region below the graph. The result $A + B$ is a good estimate for the area below the graph.

1. Review: Integrate $x^{1/3} \log(x) \, dx$

2. Review: Integrate $\log(x^5)(1/x) \, dx$

Foto taken by Oliver (while being in grad school) from his Paraglider near Lauterbrunnen in Switzerland.
Math 1A: introduction to functions and calculus

Lecture 31: Partial fractions

The partial fraction method will be covered in detail follow up calculus courses like Math 1b. Here we just look at some samples to see what's out there. We have learned how to integrate polynomials like \( x^4 + 5x + 3 \). What about rational functions? We will see that they are a piece of cake - if you have the right guide of course...

What we know already

Let's see what we know already:

- We also know that integrating \( 1/x \) gives \( \log(x) \). We can for example integrate
  \[
  \int \frac{1}{x-6} \, dx = \log(x-6) + C .
  \]
- We also have learned how to integrate \( 1/(1 + x^2) \). It was an important integral:
  \[
  \int \frac{1}{1 + x^2} \, dx = \arctan(x) + C .
  \]
  Using substitution, we can do more like
  \[
  \int \frac{dx}{1 + 4x^2} = \int \frac{du/2}{1 + u^2} = \frac{\arctan(u)}{2} = \frac{\arctan(2x)}{2} .
  \]
- We also know how to integrate functions of the type \( x/(x^2 + c) \) using substitution. We can write \( u = x^2 + c \) and get \( du = 2x \, dx \) so that
  \[
  \int \frac{x}{x^2 + c} \, dx = \int \frac{1}{2u} \, du = \frac{\log(x^2 + c)}{2} .
  \]
- Also functions \( 1/(x + c)^2 \) can be integrated using substitution. With \( x + c = u \) we get \( du = dx \) and
  \[
  \int \frac{1}{(x + c)^2} \, dx = \int \frac{1}{u^2} \, du = -\frac{1}{u} + C = -\frac{1}{x + c} + C .
  \]

The partial fraction method

We would love to be able to integrate any rational function

\[
f(x) = \frac{p(x)}{q(x)},
\]
where \( p, q \) are polynomials. This is where partial fractions come in. The idea is to write a rational function as a sum of fractions we know how to integrate. The above examples have shown that we can integrate \( a/(x + c), (ax + b)/(x^2 + c), a/(x + c)^2 \) and cases, which after substitution are of this type.

The partial fraction method writes \( p(x)/q(x) \) as a sum of functions of the above type which we can integrate.

This is an algebra problem. Here is an important special case:

In order to integrate \( \int \frac{1}{(x-a)(x-b)} \, dx \), write

\[
\frac{1}{(x-a)(x-b)} = \frac{A}{x-a} + \frac{B}{x-b} .
\]

and solve for \( A, B \).

In order to solve for \( A, B \), write the right hand side as one fraction again

\[
\frac{1}{(x-a)(x-b)} = \frac{A(x-b) + B(x-a)}{(x-a)(x-b)} .
\]

We only need to look at the numerator:

\[
1 = Ax - Ab + Bx - Ba .
\]

In order that this is true we must have \( A + B = 0 \), \( Ab - Ba = 1 \). This allows us to solve for \( A, B \).

Examples

1. To integrate \( \int \frac{2}{1-x^2} \, dx \) we can write

\[
\frac{2}{1-x^2} = \frac{1}{1-x} + \frac{1}{1+x}
\]

and integrate each term

\[
\int \frac{2}{1-x} \, dx = \log(1+x) - \log(1-x) .
\]

2. Integrate \( \int \frac{5-2x}{x^2-x+6} \, dx \). Solution. The denominator is factored as \((x-2)(x-3)\). Write

\[
\frac{5-2x}{x^2-5x+6} = \frac{A}{x-2} + \frac{B}{x-3} .
\]

Now multiply out and solve for \( A, B \):

\[
A(x-2) + B(x-3) = 5-2x .
\]

This gives the equations \( A + B = -2 \), \( -2A - 3B = 5 \). From the first equation we get \( A = -2 - B \) and from the second equation we get \( 2B + 4 - 3B = 5 \) so that \( B = -1 \) and so \( A = -1 \). We have not obtained

\[
\int \frac{5-2x}{x^2-5x+6} \, dx = -\frac{1}{x-3} - \frac{1}{x-2} .
\]

and can integrate:

\[
\int \frac{5-2x}{x^2-5x+6} \, dx = -\log(x-3) - \log(x-2) .
\]

Actually, we could have got this one also with substitution. How?

3. Integrate \( \int \frac{1}{1-2x} \, dx \). Solution. The denominator is factored as \((1-2x)(1+2x)\). Write

\[
\frac{1}{1-2x} + \frac{B}{1+2x} = \frac{1}{1-4x^2} .
\]

We get \( A = 1/4 \) and \( B = -1/4 \) and get the integral

\[
\int f(x) \, dx = \frac{1}{4} \log(1-2x) - \frac{1}{4} \log(1+2x) + C .
\]
Hopital’s method

There is a fast method to get the coefficients:

If \( a \) is different from \( b \), then the coefficients \( A, B \) in

\[
\frac{p(x)}{(x-a)(x-b)} = \frac{A}{x-a} + \frac{B}{x-b}
\]

are

\[
A = \lim_{x \to a} (x-a) f(x) = p(a)/(a-b), \quad B = \lim_{x \to b} (x-b) f(x) = p(b)/(b-a)
\]

Proof. If we multiply the identity with \( x-a \) we get

\[
\frac{p(x)}{(x-b)} = A + \frac{B(x-a)}{x-b}
\]

Now we can take the limit \( x \to a \) without peril and end up with \( A = p(a)/(x-b) \).

Cool, isn’t it? This Hopital method can save you a lot of time! Especially when you deal with more factors and where sometimes complicated systems of linear equations would have to be solved. Remember

Math is all about elegance and does not use complicated methods if simple ones are available.

Here is an example:

4 Find the anti-derivative of \( f(x) = \frac{2x+3}{(x-4)(x+8)} \). Solution. We write

\[
\frac{2x+3}{(x-4)(x+8)} = \frac{A}{x-4} + \frac{B}{x+8}
\]

Now \( A = \frac{2x+3}{x-4} = 11/12 \), and \( B = \frac{2x+3}{x+8} = 13/12 \). We have

\[
\frac{2x+3}{(x-4)(x+8)} = \frac{(11/12)}{x-4} + \frac{(13/12)}{x+8}
\]

The integral is

\[
\frac{11}{12} \log(x-4) + \frac{13}{12} \log(x+8)
\]

Here is an example with three factors:

5 Find the anti-derivative of \( f(x) = \frac{x^2+x+1}{(x-1)(x-2)(x-3)} \). Solution. We write

\[
\frac{x^2+x+1}{(x-1)(x-2)(x-3)} = \frac{A}{x-1} + \frac{B}{x-2} + \frac{C}{x-3}
\]

Now \( A = \frac{x^2+x+1}{x-1} = 3/2 \), and \( B = \frac{x^2+x+1}{x-2} = -7 \) and \( C = \frac{x^2+x+1}{x-3} = 13/2 \). The integral is

\[
\frac{3}{2} \log(x-1) + 7 \log(x-2) + \frac{13}{2} \log(x-3)
\]

And because we like it extreme, here is a larger example:

6 Find the anti-derivative of

\[
f(x) = \frac{1}{x(x-1)(x-2)(x-3)(x-4)(x-5)(x-6)(x-7)(x-8)(x-9)}
\]

Ask your friends whether they have done a partial fraction example with 10th degree polynomial in the denominator. I bet they didn’t do any. Since I have never seen such an example in a text book, look at this example as a "first":

Solution. We write

\[
f(x) = \frac{A_0}{x} + \frac{A_1}{x-1} + \frac{A_2}{x-2} + \frac{A_3}{x-3} + \frac{A_4}{x-4} + \frac{A_5}{x-5} + \frac{A_6}{x-6} + \frac{A_7}{x-7} + \frac{A_8}{x-8} + \frac{A_9}{x-9}
\]

The constants are

\[
\begin{align*}
A_0 &= \frac{\frac{\log(x)}{362880}}{1} = -1 \\
A_1 &= \frac{\log(x-1)}{10080} = 1 \\
A_2 &= \frac{\log(x-2)}{40320} = 1 \\
A_3 &= \frac{\log(x-3)}{2880} = -1 \\
A_4 &= \frac{\log(x-4)}{4320} = 1 \\
A_5 &= \frac{\log(x-5)}{10080} = 1 \\
A_6 &= \frac{\log(x-6)}{10080} = 1 \\
A_7 &= \frac{\log(x-7)}{40320} = -1 \\
A_8 &= \frac{\log(x-8)}{362880} = 1 \\
A_9 &= \frac{\log(x-9)}{362880} = 1
\end{align*}
\]

The integral is

\[
\begin{align*}
&= -\frac{\log(x)}{362880} + \frac{\log(x-1)}{40320} + \frac{\log(x-2)}{10080} + \frac{\log(x-3)}{2880} + \frac{\log(x-4)}{4320} - \frac{\log(x-5)}{10080} - \frac{\log(x-6)}{40320} - \frac{\log(x-7)}{362880}
\end{align*}
\]

Homework

1 \( \int \frac{dx}{x-1} \)
2 \( \int \frac{dx}{x+1} \)
3 \( \int \frac{x^2}{(x+1)(x+1)} dx \)
4 \( \int \frac{x^4}{(x+1)(x+1)(x+1)} dx \)
5 \( \int \frac{x^{10}+1}{x^{10}+x^{10}} dx \) Use Hopitals method of course! Hint for 3. Subtract first a polynomial.

Hint for 4. Find the nominator of \( \frac{dx}{x+1} + \frac{C}{x+1} \) and set it \( 3x^2 \). To do so, multiply out.
Lecture 40: Worksheet

Partial fractions

1. Integrate $\frac{1}{1+x}$.

2. Integrate $\frac{9}{(x-1)^7}$.

3. Integrate $\frac{7}{x^2+1}$.

4. Integrate $\frac{1}{1-x^4}$.

Hint: write the last one first in the form $\frac{A}{x^2 - 1} + \frac{B}{1 + x^2}$
Lecture 32: Trig substitutions

Trig substitution is a special case of substitution, where $x$ is a trigonometric function of $u$ or $u$ is a trigonometric function of $x$. Also this topic is covered more in follow up courses like Math 1b. This lecture allows us to practice more the substitution method.

Here is an important example:

1. The area of a half circle of radius 1 is given by the integral
   \[ \int_{-1}^{1} \sqrt{1 - x^2} \, dx \ . \]

   **Solution.** Write $x = \sin(u)$ so that $\cos(u) = \sqrt{1 - x^2}$. $dx = \cos(u)\, du$. We have $\sin(-\pi/2) = -1$ and $\sin(\pi/2) = 1$ the answer is
   \[ \int_{-\pi/2}^{\pi/2} \cos(u)\, du = \int_{-\pi/2}^{\pi/2} (1 + \cos(2u))/2 = \frac{\pi}{2} . \]

2. Compute the area of a half disc of radius $r$ which is given by the integral
   \[ \int_{-r}^{r} \sqrt{r^2 - x^2} \, dx \ . \]

   **Solution.** Write $x = r\sin(u)$ so that $r\cos(u) = \sqrt{r^2 - x^2}$ and $dx = r\cos(u)\, du$ and $r\sin(-\pi/2) = -r$ and $r\sin(\pi/2) = r$. The answer is
   \[ \int_{-\pi/2}^{\pi/2} r^2\cos^2(u) \, du = r^2\pi/2 . \]

Here is an example, where $\tan(u)$ is the right substitution. You have to be told that first. It is hard to come up with the idea:

4. Find the following integral:
   \[ \int \frac{dx}{x^2\sqrt{1 + x^2}} \]

   by using the substitution $x = \tan(u)$. **Solution.** Then $1 + x^2 = 1/\cos^2(u)$ and $dx = du/\cos^2(u)$. We get
   \[ \int \frac{du}{\cos^2(u)\tan^2(u)(1/\cos(u))} = \int \frac{\cos(u)}{\sin^2(u)} \, du = -1/\sin(u) = -1/\sin(\arctan(x)) \ . \]

Trig substitution is based on the trig identity:
\[
\cos^2(u) + \sin^2(u) = 1
\]

Depending on whether you divide this by $\sin^2(u)$ or $\cos^2(u)$ we get

\[
1 + \tan^2(u) = 1/\cos^2(u), \quad 1 + \cot^2(u) = 1/\sin^2(u)
\]

These identities are worth remembering. Let’s look at more examples:

5. Evaluate the following integral
   \[ \int \frac{dx}{\sqrt{1 - x^2}} \ . \]

   **Solution:** Substitute $x = \cos(u), dx = -\sin(u)\, du$ and get
   \[ -\int \frac{\cos^2(u)}{\sin(u)} \, du = -\int \cos^2(u) \, du = -\frac{u}{2} - \frac{\sin(2u)}{4} + C = -\arcsin(x)/2 + \frac{\sin(2\arcsin(x))}{4} + C . \]

6. Evaluate the integral
   \[ \int \frac{dx}{(1 + x^2)^2} \ . \]

   **Solution:** we make the substitution $x = \tan(u), dx = du/(\cos^2(u))$. Since $1 + x^2 = \cos^{-2}(u)$ we have
   \[ \int \frac{dx}{(1 + x^2)^2} = \int \frac{\cos(u)}{\sin^2(u)} \, du = (u/2) + \frac{\sin(2u)}{4} + C = \frac{\arctan(u)}{2} + \frac{\sin(2\arctan(u))}{4} + C . \]

Here comes an other prototype problem:

7. Find the anti derivative of $1/\sin(x)$. **Solution:** We use the substitution $u = \tan(x/2)$ which gives $x = 2\arctan(u), dx = 2du/(1 + u^2)$. Because $1 + u^2 = 1/\cos^2(x/2)$ we have
   \[ \frac{2u}{1 + u^2} = 2\tan(x/2)\cos^2(x/2) = 2\sin(x/2)\cos(x/2) = \sin(x) . \]

Plug this into the integral
   \[ \int \frac{1}{\sin(x)} \, dx = \int \frac{1 + u^2}{2u} \, du = \int \frac{1}{u} \, du = \log(u) + C = \log(\tan(x/2)) + C . \]

Unlike before, where $x$ is a trig function of $u$, now $u$ is a trig function of $x$. This example shows that the substitution $u = \tan(x/2)$ is magic. Because of the following identities
\[ u = \tan(x/2) \]
\[ dx = \frac{2u}{1+u^2} \]
\[ \sin(x) = \frac{2u}{1+u^2} \]
\[ \cos(x) = \frac{1}{1+u^2} \]

It allows us to reduce any rational function involving trig functions to rational functions.

Any function \( p(x)/q(x) \) where \( p, q \) are trigonometric polynomials can be integrated using elementary functions.

It is usually a lot of work but here is an example:

To find the integral
\[ \int \frac{\cos(x) + \tan(x)}{\sin(x) + \cot(x)} \, dx \]
for example, we replace \( dx, \sin(x), \cos(x), \tan(x) = \sin(x)/\cos(x), \cot(x) = \cos(x)/\sin(x) \)
with the above formulas we get a rational expression which involves \( u \) only. This gives us an integral \( \int p(u)/q(u) \, du \) with polynomials \( p, q \). In our case, this would simplify to
\[ \int \frac{2u (u^4 + 2u^3 - 2u^2 + 2u + 1)}{(u-1)(u+1)(u^2+1)(u^4-4u^2-1)} \, du \]
The method of partial fractions provides us then with the solution.

**Homework**

1. Find the antiderivative:
   \[ \int \sqrt{1 - 4x^2} \, dx \ . \]
2. Find the antiderivative:
   \[ \int (1 - x^4)^{1/2} \, dx \ . \]
3. Find the antiderivative:
   \[ \int \frac{\sqrt{1 - x^2}}{x^2} \, dx \ . \]
4. Integrate
   \[ \int \frac{1}{1 + \sin(x)} \]
   using the substitution \( x = \tan(u) \).
   **Hint.** Look at the example in this handout.
5. Compute
   \[ \int \frac{dx}{\cos(x)} \]
   using the substitution \( u = \tan(x/2) \).
   **Hint.** Look at the example in this handout text and use the identity \((1 - u^2)/(1 + u^2) = \cos(x)\).
Lecture 32: Worksheet

Trig Substitutions

1. Integrate $\sqrt{1 + x^2}$. Hint. Use $x = \tan(u)$.
2. Integrate $\sqrt{1 - x^2}$. Hint. Use $x = \cos(u)$.
3. Integrate $\sqrt{x^2 - 1}$. Hint. Use $x = 1/\cos(u)$.
4. Integrate $\frac{\arccos(x)}{1-x^2}$. Hint. Use $x = \cos(u)$. 
Lecture 33: Calculus and Music

A music piece is a function

Calculus plays a role in music because every music piece just is a function. If you have a loudspeaker with a membrane at position \( f(t) \) at time \( t \), then you can listen to the music. The pressure variations in the air are sound waves which reach your ear, where your eardrum oscillates with the function \( f(t - T) + g(t) \) where \( g(t) \) is background noise and \( T \) is a time delay for the sound to reach your ear. Plotting and playing works the same way. In Mathematica, we can play a function with 

\[
\text{Play[}\sin[2\pi 1000 x^2] \{x,0,10\}]\]

This function contains all the information about the music piece. A music "WAV" file contains sampled values of the function. A sample rate of 44100 per second is usual. In .MP3 files essential values are encoded in a compressed way. We take this lecture as an opportunity to review some facts about functions. We especially see that log, exp and trigonometric functions play an important role in music.

The wave form and hull

A periodic signal is the building block of sound. Assume \( g(x) \) is a \( 2\pi \) periodic function, we can generate a sound of 440 Hertz when playing the function \( f(x) = g(440 \cdot 2\pi x) \). If the function does not have a smaller period, then we hear the A tone with 440 Hertz.

The wave form and hull function is defined as the interpolation of successive local maxima of \( f \). The lower hull function is the interpolation of the local minima.

For the function \( f(x) = \sin(100x) \) for example, the upper hull function is \( g(x) = 1 \) and the lower hull function is \( g(x) = -1 \). For \( f(x) = \sin(x)\sin(100x) \) the upper hull function is approximately \( g(x) = |\sin(x)| \) and the lower hull function is approximately \( g(x) = -|\sin(x)| \).

The scale

Western music uses a discrete set of frequencies. This scale is based on the exponential function. The frequency \( f \) is an exponential function of the scale \( s \). On the other hand, if the frequency is known then the scale number is a logarithm.

The Midi numbering of musical notes is 
\[
s = 69 + 12 \cdot \log_2(f/440)
\]

1 What is the frequency of the Midi tone 100? Solution. We have to solve the above equation for \( f \) and get the piano scale function
\[
f(s) = 440 \cdot 2^{(s-69)/12}.
\]

Evaluated at 100 we get 2637.02 Hz.

The piano scale function
\[
f(s) = 440 \cdot 2^{(s-69)/12}
\]
is an exponential function \( f(s) = b e^{as} \) which satisfies \( f(s+12) = 2f(s) \).

2 Find the discrete derivative \( Df(x) = f(x+1) - f(x) \) of the Piano scale function. Solution: The function is of the form \( f(x) = Ax^s \). We have \( f(x+1) = 2^s f \) and so \( Df(x) = (2^s - 1)f \) with \( a = 1/12 \). Let's get reminded that such discrete relations lead to the important property \( \sum x \exp(ax) = a \exp(x) \) for the exponential function.

\[
\text{midifrequency[m]} := \sqrt{440 \cdot 2^{((m - 69)/12)}}
\]

The classical piano covers the 88 Midi tone scale from 21 to 108. The lowest frequency is 27.5Hz, the sub-contra-octave A, the highest 4186.01Hz, the 5-line octave C.
Decomposition in overtones: low and high pass filter It turns out that every wave form can be written as a sum of sin and cos functions. Our ear does this Fourier decomposition automatically. We can hear melodies. Here is an example of a decomposition: \( f(x) = \sin(x) + \sin(2x)/2 + \sin(3x)/3 + \sin(4x)/4 + \sin(5x)/5 \). With infinitely many terms, one can also describe discontinuous functions.

Filtering and tuning: pitch and autotune Another advantage of a decomposition of a function into basic building blocks is that one can leave out frequencies which are not good. Examples are low pass or high pass filters. A popular filter is autotune which does not filter but moves the frequencies around so that you can no more sing wrong. If 440 Herz (A) and 523.2 Herz (C) for example were the only allowed frequencies, the filter could change a function \( f(x) = \sin(2\pi 441x) + 4\cos(2\pi 521x) \) to \( g(x) = \sin(2\pi 440x) + 4\cos(2\pi 523.2x) \). This filtering is done on the wave form scale.

Mixing different functions: rip and remix If \( f \) and \( g \) are two functions which represent songs, we can look at \( (f + g)/2 \) which is the average of the two songs. In real life this is done using tracks. Different instruments can be recorded independently for example and then mixed together. One can for example get guiter \( g(t) \), voice \( v(t) \) and piano \( p(t) \) and form \( f(t) = ag(t) + bv(t) + c(p(t), \text{where the constants } a, b, c \text{ are chosen.} \)

Differentiate functions: reverb and echo If \( f \) is a song and \( h \) is some time interval, we can look at \( g(x) = Df(x) = [(f(x+h) - f(x))/h \text{. Such a differentiation is easy to achieve with a real song. It turns out that for small } h, \text{ like of order of } h = 1/1000, \text{ the song does not change much. The reason is that a frequency } \sin(kx/h) \text{ or hearing the derivative } \cos(kx/h) \text{ produces the same song. However, if we allow } h \text{ to be larger, then a reverb or echo effect is produced.} \)

Other relations with math
Symmetries. Symmetries play an important role in art and science. In geometry we know rotational, translational symmetries or reflection symmetries. Like in geometry, symmetries play a role both in Calculus as well as in Music. We see some examples in the presentation.

Mathematics and music have a lot of overlap. Besides wave form analysis and music manipulation operations and symmetry, there are encoding and compression problems. Diophantine problems like how good frequency ratios are approximated by rationals: Why is the chromatic scale based on the twelfth root of 2 so good? Indian music for example uses microtones and a scale of 22. The 12 tone scale is good because many powers \( 2^{4/12} \) are close to rational numbers. 1 once defined the “scale fitness” function

\[
M(n) = \sum_{k=1}^{\infty} \min_{p \in \mathbb{Z}} \left| k^{1/n} - \frac{1}{q} \right| G(p, q)
\]

which is a measure on how good a music scale is. It uses Euler’s gradus suavis (“degree of pleasure”) function \( G(n, m) \), a fraction \( n/m \) which is \( G(n, m) = 1 + E(n/m, \text{gcd}(n, m)) \), where the Euler gradus function \( E(n)=\sum_{p \in \mathbb{N}} c(p)(p−1) \) and \( p \) runs over all prime factors \( p \) of \( n \) and \( c(p) \) is the multiplicity. The picture to the left shows Euler’s function \( G(n, m) \), the right hand side the scale fitness function in dependence on \( n \). You see that \( n = 12 \) is clearly the winner. This analysis could be refined to include scales like Stockhausens 5\( 4/25 \)
scale. You can listen to the Stockhausen’s scale with \( f(t) = \sin(2\pi t 100 - 5^{4/25}) \), where \( [t] \) is the largest integer smaller than \( t \). Our familiar 12-tone scale can be admired by listening to \( f(t) = \sin(2\pi t 100 \cdot 2^{4/12}) \).

The perfect fifth 3/2 has the gradus suavis 1 + E(6) = 1 + 2 = 3 which is the same than the perfect fourth 4/3 for which 1 + E(12) = 1 + (2 − 1)(3 − 1). You can listen to the perfect fifth \( f(x) = \sin(1000x) + \sin(1500x) \) or the perfect fourth \( f(x) = \sin(1000x) + \sin(1333x) \) and here is a function representing an accord with four notes \( \sin(1000x) + \sin(1333x) + \sin(1500x) + \sin(2000x) \).

Homework

1. Modulation. How do the following function sound? Listen to them for 10 seconds then draw the hull function.
   a) \( f(x) = \sin(1000x) - \sin(101x) \)
   b) \( f(x) = \sin(x) + \cos(\tan(1000\sqrt{x})) \)
   c) \( f(x) = \sqrt{x} \cos(10000x) \)
   d) \( f(x) = \cos(x)\sin(e^x)/2 \)

   Here is how to play a function with Mathematica. It will play for 9 seconds:

   
   | Play[| Cos[x] | Sin[Exp[2 x]]/x, {x, 0, 10}] |
   
   Hint. You can play functions online with Wolfram Alpha. Here is an example:

   play sin (1000 x)

2. Amplitude modulation (AM): If you listen to \( f(x) = \sin(x)\sin(1000x) \) you hear an amplitude change. Draw the hull function. How many increase in amplitudes to you hear in 10 seconds?

3. Frequency Modulation (FM): If we play \( f(x) = x \sin(1000 \sin(x)) \), there are points, where the frequency is low. This is a frequency change. Draw the hull function.

4. Smoothness: If we play the function \( f(x) = \tan(\sin(3000 \sin(x))) \), the sound sounds pretty nice. If we change that to \( f(x) = \tan(2\sin(3000 \sin(x))) \), the sound is awful. Can you see why? To answer this, you might want to plot a similar function where 3000 is replaced by 3.

5. A mystery sound: How would you describe the sound \( f(x) = \sin(1/\sin(2\pi 3x)) \)? Our ear can not hear frequencies below 20 Hertz. Why can one still hear something? To answer this, you might want to plot the function from \( x = 0 \) to \( x = 10 \).
Lecture 33: Worksheet

Calculus in Music

1. How do you think the function
   \[ f(x) = \sin(10000\sqrt{x}) \]
   sounds?

2. What about
   \[ f(x) = \sin(10000x^2) \]?

3. And how about
   \[ f(x) = \arctan(x) \sin(\tan(x)1000x)) \]?

4. And finally
   \[ \sin(x) \sin(1000x) \]?
Lecture 34: Calculus and Statistics

In this lecture, we look at an application of calculus to statistics. We have already defined the probability density function $f$ and its anti-derivative, the cumulative distribution function.

Functions

In statistics, functions appear at many places. First of all for random variables. Then for probability density functions and cumulative probability density functions. In order to compute quantities like expectation and variance, we have to integrate.

The **expectation** of probability density function $f$ is

$$m = \int_{-\infty}^{\infty} xf(x) \, dx.$$  

The **variance** of probability density function $f$ is

$$\int_{-\infty}^{\infty} (x^2 - m) f(x) \, dx$$

where $m$ is the expectation. The square root of the variance is the **standard deviation**.

The expectation of the normal distribution

$$f(x) = \frac{1}{2\pi\sigma^2} e^{-(x-m)^2/(2\sigma^2)} \, dx$$

is equal $m$. The standard deviation is $\sigma$.

The expectation of the geometric distribution $f(x) = e^{-ax}$

$$\int xe^{-ax} \, dx = \frac{1}{a}.$$  

The variance of the geometric distribution $f(x) = e^{-ax}$ is $1/a^2$ and the standard deviation $1/a$.

To see this, compute (remember Tic Tac Toe!)

$$\int x^2 e^{-ax} \, dx = \frac{2}{a^3}.$$
Lecture 34: Calculus and Statistics

A random variable \( X \) is a variable that can take one of many values depending on the outcome of some random process.

For example, \( C \) could be the random variable that represents the number of heads after flipping a coin twice. Then the probability of getting 0 for \( C \) is \( P(C = 0) = \frac{1}{4} \). Likewise, \( P(C = 1) = \frac{1}{2} \) and \( P(C = 2) = \frac{1}{4} \). If a random variable \( X \) is discrete, taking on integer values, it must always be true that

\[
\sum_k P(X = k) = 1;
\]

in other words, the sum of the probabilities of all possible outcomes is 1 (100%).

The expected value of a random variable \( X \), denoted \( E[X] \), is the mean, or our single best guess (“expectation”) for what any given value of \( X \) might be. For a discrete random variable \( X \), the expectation is

\[
\sum_k k \cdot P(X = k),
\]

For our variable \( C \) evaluates to \( 0 \cdot P(C = 0) + 1 \cdot P(C = 1) + 2 \cdot P(C = 2) = 0 \cdot \frac{1}{4} + 1 \cdot \frac{1}{2} + 2 \cdot \frac{1}{4} = 1 \); in other words, if we flip a coin twice many times, on average we’ll get 1 head for each pair of flips.

The variance of a random variable \( X \), denoted \( \text{Var}[X] \), is a measure of how spread apart a distribution is (how likely we are to get values of \( X \) that are far from the mean). It is

\[
\sum_k (k - E[X])^2 P(X = k),
\]

which for our variable \( C \) evaluates to \( (0 - 1)^2 P(C = 0) + (1 - 1)^2 P(C = 1) + (2 - 1)^2 P(C = 2) = \frac{1}{4} + 0 + 1 = \frac{3}{4} \). Note that we are basically just adding up \( (k - E[X])^2 \) (which is 0 when \( k \) is at the mean of \( X \) and gets larger when \( k \) gets further away from the mean) and weighting it by the probability of having \( X = k \).

Now let’s consider a continuous random variable \( X \) that could take on any real number.

As an example, \( H \) might be the height, in inches, of a randomly chosen Harvard student. Note that since \( H \) is continuous, \( P(H = h) = 0 \) for any particular height \( h \), so it makes more sense to talk about \( P(h \leq H < h + \epsilon) \) for some small \( \epsilon > 0 \).

For a random variable, the probability density function for that random variable is a function \( f(x) \) such that

\[
P(a \leq X \leq b) = \int_a^b f(x) \, dx.
\]

You can probably see where we are going with this: instead of the sum of all probabilities being 1, it will instead be the case that

\[
\int_{-\infty}^{\infty} f(x) \, dx = 1.
\]

Similarly, the expected value of a continuous distribution \( X \) is

\[
E[X] = \int_{-\infty}^{\infty} x \cdot f(x) \, dx
\]

and the variance is

\[
\text{Var}[X] = \int_{-\infty}^{\infty} (x - E[X])^2 \cdot f(x) \, dx.
\]

Our height distribution \( H \) would have what is called a normal probability density function. (Many natural quantities follow a normal distribution.)

The normal probability density function is

\[
f(x) = \frac{1}{\sigma \sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2}.
\]

If \( X \) has a normal distribution, then

\[
E[X] = \int_{-\infty}^{\infty} x \cdot f(x) \, dx = \mu \quad \text{and} \quad \text{Var}[X] = \int_{-\infty}^{\infty} (x - \mu)^2 \cdot f(x) \, dx = \sigma^2.
\]

Not every distribution is normal, though. For example, incomes are not normally distributed: most people have relatively moderate incomes, but no one has a negative income and there are a few people that have very high incomes. Some people (see below) argue that income follows an exponential distribution, a distribution with probability distribution function \( f(x) = \lambda e^{-\lambda x} \) (where \( \lambda > 0 \) is a constant).

Exponential distributions have mean

\[
E[X] = \int_{0}^{\infty} x \lambda e^{-\lambda x} \, dx = \frac{1}{\lambda}
\]

and variance

\[
\text{Var}[X] = \int_{0}^{\infty} (x - \frac{1}{\lambda})^2 \lambda e^{-\lambda x} \, dx = \frac{1}{\lambda^2}.
\]

Another quantity of interest is the cumulative distribution function, which is

\[
F(x) = P(X \leq x) = \int_{0}^{x} f(x) \, dx.
\]

For our income function, the mean household income in the US in 1997 is a random variable \( I \) that is exponentially distributed with mean \$35,200\(^4\), so \( \lambda = 1/35200 \). The probability that a randomly selected person makes $100,000 or less is

\[
P(I \leq 100000) = \int_{0}^{100000} \frac{1}{35200} e^{-t/35200} \, dt = 1 - e^{-100000/35200} = 94%.
\]

The probability density function \( f(x) = (a - 1)/x^a \) represents a power law distribution, where \( a > 1 \) is a constant parameter that changes the shape of the distribution.

Homework

1. The uniform distribution on \([a, b]\) is a distribution where any real number between \(a\) and \(b\) is equally likely to occur. The probability density function is \(f(x) = 1/(b - a)\) for \(a \leq x \leq b\) and 0 elsewhere. Verify that \(f(x)\) is a valid probability density function (i.e., check that it integrates to 1).

2. Find the mean of the uniform distribution on \([a, b]\).

3. Explain why the mean you found in problem 2 makes sense intuitively.

4. The Cauchy distribution is important in physics. It has a probability density function of
\[
f(x) = \frac{b}{\pi (x - m)^2 + b^2}.
\]
Verify that \(f(x)\) is a valid probability density function.

5. Find the cumulative distribution function \(F(x)\) for the Cauchy distribution.
Lecture 34: Calculus and Statistics

In this lecture, we look at an application of calculus to statistics. We have already defined the probability density function \( f \) and its anti-derivative, the cumulative distribution function.

This lecture is given by Brian Lukoff. This document is what I had prepared for this lecture. Brian’s handout will be the official course note.

Functions

In statistics, functions appear at many places. First of all for random variables. Then for probability density functions and cumulative probability density functions. In order to compute quantities like expectation and variance, we have to integrate.

The **expectation** of probability density function \( f \) is

\[
m = \int_{-\infty}^{\infty} x f(x) \, dx .
\]

The **variance** of probability density function \( f \) is

\[
\int_{-\infty}^{\infty} (x^2 - m) f(x) \, dx
\]

where \( m \) is the expectation. The square root of the variance is the **standard deviation**.

The expectation of the normal distribution

\[
f(x) = \frac{1}{2\pi\sigma^2} e^{-(x-m)^2/(2\sigma^2)} \, dx
\]

is equal \( m \). The standard deviation is \( \sigma \).

The expectation of the geometric distribution \( f(x) = e^{-ax} \)

\[
\int xe^{-ax} \, dx = 1/a .
\]

The variance of the geometric distribution \( f(x) = e^{-ax} \) is \( 1/a^2 \) and the standard deviation \( 1/a \).

To see this, compute (remember Tic Tac Toe!)

\[
\int x^2 e^{-ax} \, dx = 2/a^3 .
\]

More Problems

1. The **uniform distribution** on \([a, b]\) is the probability density function which is zero for \( x \) outside the interval \([a, b]\) and equal to \( 1/(b-a) \) for \( x \in [a, b] \). Find the mean and standard deviation of this density.

2. The **Laplace distribution** is also called the double exponential distribution. It has the density \( 1/(2a) e^{-|x|} \). Find the mean and standard deviation of the Laplace distribution.

3. The **Logarithmic distribution** on \([1, 2]\) has the density \( C \log(x) \), where \( C \) is a constant which makes it a density. What is the constant \( C \)?

4. The **Rayleigh distribution** is the probability density which is 0 for \( x < 0 \) and \( xe^{-x^2/(2\sigma^2)}/\sigma^2 \) for \( x > 0 \). Verify that its mean is \( \sigma \sqrt{\pi/2} \) and its variance is \( (4 - \pi)\sigma^2/2 \).

5. The **Maxwell distribution** is the probability density which is zero for \( x < 0 \) and \( \frac{2}{\pi} x^2 e^{-x^2/(2\sigma^2)}/\sigma^2 \) for \( x \geq 0 \). Verify that its mean is \( 4a/\sqrt{2\pi} \) and its variance is \( a^2(3\pi - 8)/\pi \).
Lecture 35: Calculus and Economics

In this lecture we look more at applications of calculus and focus mostly on economics. This is an opportunity to review extrema problems.

Marginal and total cost

Recall that the **marginal cost** was defined as the derivative of the **total cost**. Both, the marginal cost and total cost are functions of the quantity of goods produced.

1. Assume the total cost function is \( C(x) = 10x + 0.01x^2 \). Find the marginal cost and the place where the total cost is maximal. **Solution**: Differentiate.
2. You sell spring water. The marginal cost to produce depends on the season and given by \( f(x) = 10 - 10 \sin(2x) \). For which \( x \) is the total cost maximal?
3. The following example is adapted from the book "Dominik Heckner and Tobias Kretschmer: Don’t worry about Micro, 2008", where the following strawberry story appears: (verbatim citation in italics): Suppose you have all sizes of strawberries, from very large to very small. Each size of strawberry exists twice except for the smallest, of which you only have one. Let us also say that you line these strawberries up from very large to very small, then to very large again. You take one strawberry after another and place them on a scale that sells you the average weight of all strawberries.

The first strawberry that you place in the bucket is very large to very small, then to very large again. You take one strawberry after another and place them on a scale that sells you the average weight of all strawberries. The first strawberry that you place in the bucket is very large, while every subsequent one will be smaller until you reach the smallest strawberry. Because of the literal weight of the heavier ones, average weight is larger than marginal weight. Average weight still decreases, although less steeply than marginal weight. Once you reach the smallest strawberry, every subsequent strawberry will be larger which means that the rate of decrease of the average weight becomes smaller and smaller until eventually, it stands still. At this point the marginal weight is just equal to the average weight.

Lets recall that if \( F(x) \) is the total cost function in dependence of the quantity \( x \), then \( F' = f \) is called the **marginal cost**.

The function \( g(x) = F(x)/x \) is called the **average cost**.

A point where \( f = g \) is called a **break even point**.

4. If \( f(x) = 4x^3 - 3x^2 + 1 \), then \( F(x) = x^4 - x^3 + x \) and \( g(x) = x^3 - x^2 + 1 \). Find the break even point and the points where the average costs are extremal. **Solution**: To get the break even point, we solve \( f - g = 0 \). We get \( f - g = x^2(3x - 4) \) and see that \( x = 0 \) and \( x = 4/3 \) are two break even points. The critical point of \( g \) are points where \( g'(x) = 3x^2 - 4x \). They agree.

Volume extremization

1. Assume the cost to heat a room is \( V(x) + A(x) - \pi L(x) \) where \( V \) is its volume, \( A \) the surface area and \( L(x) = \pi x \) is proportional to length \( x \). A conference center hall is is eighth of a sphere. Its volume, surface area and length are

\[
V(x) = \frac{4}{3} \pi x^3, A(x) = \frac{4}{3} \pi x^2 + \frac{3 \pi}{4} x^2, L(x) = \pi x .
\]

The costs are \( \pi/6x^3 + (3\pi/4 + 4\pi/8)x^2 - \pi x \). To extremize the cost, we can minimize \( f(x) = x^3/6 + 5x^2/4 - x \).

The minimum is achieved at \( x = (-5 + \sqrt{3})/2 \).

2. A cone shaped solar loudspeaker has to be a cone of volume \( \pi \). For optimal charging features, the sum of vertical and horizontal shadow areas \( h \pi + \pi r^2 \) need to be extremized. Can you get a minimum or maximum? **Solution**: Lets first compute the volume of a cone
with maximal radius \( r \) and height \( h \). At height \( z \), the radius is \( rz/h \). At \( z \) the surface area is \( A(z) = \pi(hz/r)^2 \) so that the volume is

\[
V = \int_0^h \pi(r^2z^2/h^2) \, dz = \pi r^2 h / 3 = \pi .
\]

This means \( h = 3/r^2 \) and \( hr = 3/r \). The cross section is \( f(r) = \pi r^2 + 3/r \). Setting \( f'(r) = 0 \), we get the critical point \((3/(2\pi))^{1/3}\).

---

### Homework

1. Verify the Strawberry theorem in the case \( f(x) = \cos(x) \).

2. The **production function** in an office gives the production \( Q(L) \) in dependence of labor \( L \). Assume \( Q(L) = 500L^3 - 3L^5 \). Find \( L \) which gives the maximal production.

   This can be typical: For smaller groups, production usually increases when adding more workforce. After some point, bottlenecks occur, not all resources can be used at the same time, management and bureaucracy is added, each individuum has less impact and feels less responsible, meetings slow down production etc. In this range, adding more people will decrease the productivity.

3. **Marginal revenue** \( f \) is the rate of change in total revenue \( F \). As total and marginal cost, these are functions of the cost \( x \). Assume the total revenue is \( F(x) = -5x - x^3 + 9x^3 \).

   Find the point, where the total revenue has a local maximum.

4. To find the line \( y = mx \) through the points \( (3, 4), (6, 3), (2, 5) \). We have to minimize the function

   \[
   f(m) = (3m - 4)^2 + (6m - 3)^2 + (2m - 5)^2 .
   \]

5. For any \( a \) we look at the solid obtained by rotating the graph of the function \( f(r) = a \sin(r/a) \) around the axes over the interval \([0, \pi/a] \). For which \( a \) is the volume locally maximal?

   P.S. You can see the graph of the volume \( V(a) \) in dependence of \( a \) below. There are many local maxima. The problem is to find them.

---

Lecture 35: Worksheet

Calculus in Economics

The fact that extremisation is a big deal in economics is already in the word. We look at more examples. Assume we have a couple of data points and we want to find the best line $y = mx$ through this in the sense that the sum of the squares of the points to the line is minimal. This leads to an extremal problem which is a special case of a data fitting problem. It would be more adequate to fit with lines $y = mx + b$ or more generally with functions but then we have more variables and run into multivariable calculus or linear algebra problems much outside the scope of this course. But if we have only one parameter, we get a single variable calculus problem.

1. Find the best line $y = mx$ through the points $(1, 1), (3, 2), (2, 5)$. We have to minimize the function.

   \[ f(m) = (m - 1)^2 + (3m - 2)^2 + (2m - 5)^2 \]

   Find the minimum. Solution. 17/14

2. Find the best line $y = x + b$ through the points $(1, 2), (2, 5), (-1, 2), (4, 7)$. Let's take a different set of data points and look at the problem to fit functions of the form $y = x + b$. 
9.5 The Connection Between Marginal and Average Costs

This section is slightly more technical than the rest of this chapter. The subject of our analysis at this point is the connection between different cost curves. To be more precise, we investigate how the MC curve cuts through the average cost curves at their respective minima. This is shown in Fig. 9.4.

Shutdown and Break Even Points

Before we commence with our analysis, let us link the graph back to some of the discussion above. Looking at Fig. 9.4 you may have noticed that the two quantities for the intersection of MC with AVC and MC with ATC are labelled $Q_0$ and $Q_1$. These are the shutdown and break even points, respectively.

The MC curve crosses the AVC and ATC curves at their respective minima.

As we discussed previously, when employing the profit-maximizing condition and when AVC is equal to MC, we would be just indifferent between shutting down or producing in the short run. Secondly, when we set price equal to MC and when at this point MC is also equal to ATC, the firm is just breaking even.

![Fig. 9.4. The marginal cost MC curve cuts through average variable cost AVC and average total cost ATC curves at their respective minima. These points are the shutdown and break-even points, respectively.](image)

You take one strawberry after another and place them on a scale that tells you the average weight of all strawberries. The first strawberry that you place in the bucket is very large, while every subsequent one will be smaller (until you reach the smallest one). Because of the literal "weight" of the heavier ones, average weight is larger than marginal weight (i.e. the weight of each strawberry you handle). Average weight still decreases, although less steeply than marginal weight.

Once you reach the smallest strawberry, every subsequent strawberry will be larger, which means that the rate of decrease of the average weight becomes smaller and smaller until eventually it stands still. At this point, the marginal weight is just equal to the average weight.

This logic is an analogy of why MC cuts through the average cost curves at their minimum. The reasoning is identical for both AVC and ATC.

**Mathematical Proof**

Rather than blindly trusting the intuition above, we can also prove our analysis mathematically. Let us perform this proof for the intersection of MC and ATC. Our first step is to compute the derivative of ATC with respect to $Q$ and set this equal to zero to find the curve's critical point, hence the minimum:

$$\frac{d\text{ATC}}{dQ} = 0$$

(9.14)

In order to make Equation 9.14 usable, let us substitute $TC/Q$ for ATC. Therefore, we get:

$$\frac{d(TC/Q)}{dQ} = 0$$

(9.15)

To avoid complicated calculus, let us reformulate the numerator as a product:

$$d(TC/Q) = 0$$

(9.16)

Remembering the **product rule**, we differentiate $TC \cdot Q^{-1}$ with respect to $Q$ by taking the derivative of the first term and multiplying it by the second, and adding the derivative of the second term and multiplying it by the first. This gives us:

$$\frac{dTC}{dQ} Q^{-1} - TC \cdot Q^{-2} = 0$$

(9.17)

Notice the negative sign between the terms, which is a result of the "brought down" from $Q^{-1}$ of Equation 9.16 in the process of differentiation. When looking at Equation 9.17, we notice that the very first term is MC and so we can write:

$$MC \cdot Q^{-1} - TC \cdot Q^{-2} = 0$$

(9.18)

As a final step we multiply both sides by $Q$ and write the second term as a fraction:

$$MC - \frac{TC}{Q} = 0$$

(9.19)

Since, by definition, $TC/Q$ is equal to ATC, we finalize our equation to become:

$$MC - ATC = 0$$

(9.20)

Now our task of proving that ATC is equal to MC when ATC is at its minimum is easy. Having taken the derivative of ATC in Equation 9.14 to show its minimum, we have worked all the way to Equation 9.20. This last equation will hold true, i.e. will correspond to a minimum of the ATC curve when we set MC and ATC equal to each other. Hence, when MC is equal to ATC, ATC is at its minimum. The same mathematical steps can be followed to prove the intersection of AVC and MC at the minimum of AVC.

Lecture 36: Artificial intelligence

Today, we study the intriguing question in AI:

What does it take to build an artificial calculus teacher?

Machines assist us already in many domains: heavy work is done by machines and robots, accounting by computers and fighting by drones. Lawyers and doctors are assisted by artificial intelligence. There is no reason why teaching is different. The web has become a "gigantic brain" to which virtually any question can be asked or googled: "Dr Know" in Spielberg’s movie "AI" is humbled: enter symptoms for an illness and get a diagnosis, enter a legal question and find previous cases. Enter a calculus problem and get an answer. Building an artificial calculus teacher involves calculus itself: such a bot must connect dots on various levels: understand questions, read and grade papers and exams, write good and original exam questions, know about learning and pedagogy. Ideally, it should also have "ideas" like to "make a lecture on artificial intelligence". But first of all, our AI friend needs to know calculus and be able to generate and solve calculus problems.¹

Generating calculus problems

Having been involved in a linear algebra book project once, helping to generating solutions to problems, I know that some calculus books are written with help of computer algebra systems. They generate problems and solutions. This applies mostly to drill problems. In order to generate problems, we first must build random functions. Our AI engine "sofia" knew how to generate random problems with solutions. Random functions are involved when asked "give me an example of a function". This is easy: the system would generate functions of reasonable complexity:

```
Call the 10 functions \{ \sin, \cos, \log, \exp, \tan, \sec, \csc, \sec, \csc \} basic functions. 
Here \sqrt[4]{x} and \tan(x) = 1/x for a random integer \( k \) between \(-1\) and \( -3 \), \( \sin(x) = x^k \) for a random integer \( k \) between 2 and 5. \( \sec(x) = kx \) is a scalar multiplication for a random nonzero integer \( k \) between \(-3\) and \( 3 \) and \( \tan(x) = x + k \) for a random integer \( k \) between \(-4\) and \( 4 \).
```

Second, we use addition, subtraction multiplication, division and composition to build more complicated functions:

A basic operation is an operation from the list \{ \( f, g, f \circ g, f * g, f / g, f - g \) \}.

The operation \( x^g \) is not included because it is equivalent to \( \exp(x \log(y)) = \exp o(x \cdot \log) \). We can now build functions of various complexities:

¹In the academic year of 2003/2004, thanks to a grant from the Harvard Provost, I could work with undergraduates Johnny Carlson, Andrew Chi and Mark Lezama on a “calculus chat bot”. We spent a couple of hours per week to enter mathematics and general knowledge, build interfaces to various computer algebra systems like Pari, Mathematica, Macsyma and build a web interface. We fed our knowledge to already known chat bots and newly built ones and even had various bots chat with each other. We conventionally explored the question of automated learning of the bots from the conversations as well as to add context to the conversation, since bots needs to remember previous topics mentioned to understand some questions. We learned how immense the task is. In the mean time it has become business. Companies like Wolfram research have teams of mathematicians and computer scientists working on content for the “Wolfram alpha” engine. Having recently seen a group at work here in Cambridge on Mass Av, I guess they generate probably in one day as much content as our Sofia group could do in a week for our “pet project”.

A random function of complexity \( n \) is obtained by taking \( n \) random basic functions \( f_1, \ldots, f_n \), and \( n \) random basic operators \( \oplus, \ldots, \ominus \) and forming \( f_n \oplus f_{n-1} \ominus \cdots \oplus f_1 \oplus f_0 \) where \( f_0 = x \) and where we start forming the function from the right.
Corner detection

How do we detect corners in pictures? This is necessary to understand pictures, drawings. It might also be needed to see whether a given function is reasonably shaped. There should not be too many "wiggles" for example. There are various techniques to measure that. One of the best methods in computer vision uses the notion of curvature:

Given a function \( f(x) \), define the curvature as

\[
  k(x) = \frac{f''(x)}{(1 + f'(x)^2)^{3/2}}.
\]

Is is a measure on how much the curve is bent at the point \((x, f(x))\). Positive curvature means the curve is concave up, otherwise concave down.

8 For a quadratic function \( f(x) = x^2 \), we have \( k(x) = 1/(1 + x^2) \). We see that the curvature is maximal at the lowest part of the parabola.

9 For the function \( f(x) = \sqrt{1 - x^2} \), we have \( f'(x) = -2x/\sqrt{1 - x^2} \) and \( f''(x) = -(1-x^2)^{-3/2} \). We have \( (1 + f'(x)^2) = 1/(1 - x^2) \) and \( k(x) = -1 \).

10 Problem: Find the curvature for the graph of \( f(x) = x^5/5 - x \). Where is the curvature maximal?

Connecting the dots

We want to connect points \( P_1, \ldots, P_n \) by a smooth graph. This "connecting the dots" problem is quite frequent. Our brain does this automatically. We need to see a few glances to "see" the motion of an object and predict where it will end. We need to connect dots if we drive a car, if we interpret a picture etc. On a more abstract level, we need to connect dots in the landscape of ideas whenever we solve a problem. We want to go from \( A \) to \( B \) and need to construct intermediate steps.

Here is a simple method found by G. Chaikin in 1974\(^2\) which generates a smooth curve through a few points.

Given a sequence of \( n \) points \( P_1, \ldots, P_n \) define a new sequence of \( 2n - 2 \) points \( R_2, \ldots, R_{2n-1} \) by

\[
  R_{2i} = \frac{3}{4} P_i + \frac{1}{4} P_{i+1}, \quad R_{2i+1} = \frac{1}{4} P_i + \frac{3}{4} P_{i+1}
\]

for \( i = 1, \ldots, n-1 \).

One such a step defines a Chaikin step. The limiting curve is called the Chaikin curve defined by the original points. The picture should explain how we get the new points from the old ones: divide each segment into 4 pieces and use the two outer points to get new points.

The Chaikin steps produce a smooth curve approximating a given set of points.

The pictures show curves in two and three dimensions after applying the method a few times. The method can be used for example to study the complexity of random knots. To answer the question stated initially: like artists have become better using computers it could well be that AI will assist teachers in the future and help them to be more efficient.

In any way, the AI dragon breathing down our necks will force us all to stay creative.

**Homework**

1. A calculus bot wants to build a differentiation problem by combining log and sin and exp. Differentiate all of the 6 combinations \( \log(\exp(\sin(x))) \), \( \log(\exp(\sin(x))) \), \( \exp(\log(\sin(x))) \), \( \exp(\log(\sin(x))) \), \( \sin(\log(\sin(x))) \), \( \sin(\log(\sin(x))) \) and \( \exp(\log(\sin(x))) \).

2. Four of the 6 combinations of log and sin and exp can be integrated as elementary functions. Do these integrals.

3. Find the curvature of the sine curve at \( x = 0, x = \pi/2 \) and \( x = 3\pi/2 \).

4. Draw the points \((0, \sin(0)), (\pi/2, \sin(\pi/2)), (\pi, \sin(\pi)), (3\pi/2, \sin(3\pi/2)), (2\pi, \sin(2\pi))\) and connect them with lines. Now do Chaikin iteration for at least 2 generations on paper.

5. Answer each of the following 5 human questions in one sentence:
   a) What is calculus for you?
   b) What is the nicest application of calculus?
   c) Who invented calculus and why?
   d) What is the fundamental theorem and why is it useful?
Lecture 36: Worksheet

This worksheet was authored by Sofia, an artificial intelligence calculus teacher and student! The bot could also learn even so only in a primitive way. It had to be told “learn: ...”. This entire LaTeX file was generated automatically, (except for this introduction section which has, (thanks to this parenthesis) become self-aware and so artificially intelligent.)

Derivatives

Differentiate the following functions: Level 1

1. a) \( f(x) = x \tan(x) \)
   b) \( f(x) = x + \tan(x) \)
   c) \( f(x) = x \log(x) \)
   d) \( f(x) = e^{-x}x \)
   e) \( f(x) = \cos(x) \)

Integrals

Integrate the following functions: Level 1

1. a) \( f(x) = \frac{1}{x^2} + 1 \)
   b) \( f(x) = \sec^2(x) \)
   c) \( f(x) = 1 - \sin(x) \)
   d) \( f(x) = \sec^2(x) + 1 \)
   e) \( f(x) = \frac{1}{2\sqrt{x}} \)

---

1Written in the academic year 2003/2004, thanks to a grant from the Harvard Provost together with Johnny Carlsson, Andrew Chi and Mark Lezama. Sofia was a chat bot which would use computer algebra systems to solve calculus problems while chatting, similar to Wolfram Alpha now. The later is of course much more sophisticated. Ours was maybe a 25 week * 4 people * 15 hour = half a person-year project.
Derivatives

Differentiate the following functions: Level 2

1 a) \( f(x) = x^{3/2} \sec(x) \)
   b) \( f(x) = e^{-x}(x + \sin(x)) \)
   c) \( f(x) = 0 \)
   d) \( f(x) = e^{-x} \sqrt{x} \)
   e) \( f(x) = \frac{e^x}{\log(e^x)} \)

Integrals

Integrate the following functions: Level 2

1 a) \( f(x) = \frac{x^3 - 3}{x^4} \)
   b) \( f(x) = \frac{3\sqrt{x^3 - 3}}{2} \)
   c) \( f(x) = e^x(\cos(x) - \sin(x)) \)
   d) \( f(x) = x - x \tan^2(x) - \tan(x) \)
   e) \( f(x) = e^x \left( \sin(e^x) + e^x \cos(e^x) \right) \)

Derivatives

Differentiate the following functions: Level 3

1 a) \( f(x) = x^2(x - \tan(x)) \)
   b) \( f(x) = \sqrt{x} - \log(x) + x \tan(x) \)
   c) \( f(x) = \frac{e^{-x}}{(x-1)x^2} \)
   d) \( f(x) = \frac{e^{-x}(x+\log(x))}{x} \)
   e) \( f(x) = x^3(x + \log(x)) \)

Integrals

Integrate the following functions: Level 3

1 a) \( f(x) = -\frac{4x^4 + 1}{x} \)
   b) \( f(x) = e^{-x}((-x \log(x) + \log(x) + 1) \sin(x) + x \log(x) \cos(x)) \)
   c) \( f(x) = e^{-2x}(1 - 2x) - \sec^2(x) \)
   d) \( f(x) = e^x + \sec^2(x) \)
   e) \( f(x) = \frac{(\log(x) - 2) \cos(\sqrt{x}) - \sqrt{x} \log(x) \sin(\sqrt{x})}{\sqrt{x} \log^2(x)} \)
**Derivatives**

Differentiate the following functions: Level 4

1. a) \( f(x) = \frac{x}{x+1} \)
   b) \( f(x) = (x^3 - \sqrt{x^3} - x - 4) \csc(x) \)
   c) \( f(x) = (e^{-3x} - 9x) \cot(x) \)
   d) \( f(x) = e^{-x}((x-3)(x-2) - \cos(x)) \)
   e) \( f(x) = \frac{\sin^3(x)+\sin(x)+\sin(\sin(x))}{x+1} \)

**Integrals**

Integrate the following functions: Level 4

1. a) \( f(x) = \frac{x}{x+1} \)
   b) \( f(x) = (x^3 - \sqrt{x^3} - x - 4) \csc(x) \)
   c) \( f(x) = (e^{-3x} - 9x) \cot(x) \)
   d) \( f(x) = e^{-x}((x-3)(x-2) - \cos(x)) \)
   e) \( f(x) = \frac{\sin^3(x)+\sin(x)+\sin(\sin(x))}{x+1} \)

**Derivatives**

Differentiate the following functions: Level 6

1. a) \( f(x) = \frac{1}{x^{3/2}} + (\sqrt{x+\log(x)}) \cos \left( \frac{x^3+\log(x)}{\sqrt{x^3+\log(x)}} \right) \)
   b) \( f(x) = -(x+3) \sin^2(x)(\tan(x)) - \log(\tan(\sin(x))) \)
   c) \( f(x) = \frac{1}{x^2} - \frac{2x(x^{\log(x)^{-\log(x)}})}{x^3} + \sin (x) \)
   d) \( f(x) = x^5 \left( x^4 - x + e^x - \cos(x) \right) - x^3 \)
   e) \( f(x) = \sec(x) \left( \sin^6(x) + \sin(\sin(x)) + \tan(\sin(x)) \right) - e^x \)

**Integrals**

Integrate the following functions: Level 6

1. a) \( f(x) = \frac{\sec(x)(\sec(x) \log(\tan(x)))}{8 \sqrt{\tan(x)} \sin \left( \sqrt{\tan(x)} + 3 \sin(3 \sqrt{\tan(x)}) \right)} - \frac{\sec(x) \log(\tan(x))}{8 \sqrt{\tan(x)} \log^2(\tan(x))} \)
   b) \( f(x) = \frac{1}{2} \left( \frac{1}{\sqrt{x}} - \frac{e^{-x} \left( \frac{x^2 \log x+\log x}{\log x} \right)}{x^2} \right) - 2 e^{-x} \left( \frac{1}{\log x} + \frac{1}{2 (\log x-2)} \right) \)
   c) \( f(x) = \frac{x^2 \log x \sec^2(x) + 2x^4(3 \log(x)-1) \tan(x) + \log^2(x)}{x^2 \log^2(x)} \)
   d) \( f(x) = \frac{5x^2+10x^3-24x^4+2}{2x^2} \)
   e) \( f(x) = \frac{-2x^2 \sqrt{\cos(x)+x \log(x) \sin(x)+(6 \log(x)-2) \cos(x)}}{2 x^4 \sqrt{\cos(x)}} \)
Lecture 37: The lighter side of Calculus

First some serious final thoughts:

The holographic picture

Any knowledge can be organized in a holographic way, where the amount of detail is a parameter. A 1 second version is

Calculus is great.

Calculus in 10 seconds would be

"Calculus establishes that two operations on functions f are related: first the derivative of f which is the rate of change of f second the integral of f which is the area under the graph of f."

In 1 minute I would say something similar than in the synopsis provided by the Harvard registrar for this single variable calculus course:

The development of calculus by Newton and Leibniz is a major achievement of the past millennium. The core of this course introduces differential and integral calculus. Differential calculus studies the "rate of change" f' of a function, integral calculus treats "accumulation" \( \int_a^b f(x) \, dx \) which can be interpreted as "area under the curve". The fundamental theorem of calculus links the two: it tells that

\[
\int_a^b f'(t) \, dt = f(b) - f(a), \quad \frac{d}{dx} \int_a^b f(t) \, dt = f(x).
\]

The subject can be applied to problems from other scientific disciplines like economics (the strawberry theorem for total, average and marginal costs), reasoning for relating quantities (like estimating the speed of an airplane from angle change, psychology (catastrophes explaining revolutionary changes or flips in human perception), geometry (volume and area computation), statistics (distribution and cumulative distribution functions) or everyday life (the wobbly table theorem).

Here is an attempt to summarize the most important points of this course in 3 minutes:

1. Calculus relates two fundamental operations, the derivative measuring the rate of change of a function and the derivative which measures the area under the graph.
2. Taking derivatives is done with the chain, product and quotient rules, taking intervals with substitution including trig substitution, integration by parts and partial fraction rules.
3. Basic functions are polynomials and exp, log, sin, cos, tan. We can add, subtract, multiply, divide and compose functions, we can differentiate and integrate them.
4. A function is continuous at p if \( f(x) \to f(b) \) for \( x \to p \). It is differentiable at p if \( (f(x+h) - f(x))/h \) has a limit for \( h \to 0 \). Limits from the right and left should agree.
5. To extremize a function, look at points where f'(x) = 0. If f''(x) < 0 we have a local minimum, if f''(x) > 0 we have a local maximum. There can be critical points f'(x) = 0 without being extremum like x^4.
6. To relate how different quantities change in time, differentiate the formula relating the quantities using the chain rule. If there is a third time variable, then this is the story of related rates, if one of the variables is the parameter, then this is implicit differentiation.

We will have a 90 minute review of all the material before the midterm. It would not fit on the 4 pages which I strictly allocated as a handout for each lecture. We have seen a 37+13 hour version of the material in the lectures and problem sessions for this course. It would be possible to teach this course using 100 hours. One could explore the material more from a historical perspectives for example and read original sources. One could do projects, use more computer algebra systems, practice visualization and visualize things. You have studied maybe 300 hours for this course including homework, reading, and discussing the material. Years would be needed to study it more on a research level. New calculus is constantly developed. I myself have been working mostly on more probabilistic versions of calculus which allows to bypass some of the difficulties when discretizing calculus. The loss of symmetries obtained by discretization can be compensated differently.

The future of calculus

Calculus will undoubtedly look different in 50 years. Many changes have already started, not only on the context level, also from outside: Calculus books will be gone, electronic paper which will be almost indistinguishable from real paper has replaced it. Text, computations, graphics are all fluid in that we can at any point adjust the amount of details. Similarly than we can zoom into a map or picture by pinching the screen, we can triple pinch a text or proof or picture. As we do so, more details are added, more steps of a calculation added, more information included into a graph etc. Every picture is interactive can turn in a movie, an animation, parameters can be changed, functions deformed with the finger. Every picture is a little laboratory. Questions can be asked directly to the text and answers provided. The text can at any time be set back to an official textbook version of the course. The teacher has the possibility to set global preferences and toss work to compress and expand knowledge can be done computer assisted.

Calculus courses after 1a
To prepare for this course, I set myself the task to formulate the main topic in one short sentence and then single out 4 major goals for the course, then build titles for each lecture etc Here are 4 calculus courses at Harvard drawn out at the level of a "4 point summary". At other schools of higher education, there are similar courses.

**The course 1A** from extremization to the fundamental theorem

- Functions: polynomials, exp, log, trig functions
- Limits: velocity, tangents, infinite limits
- Derivatives: product, chain rule with related rates, extremization
- Integrals: techniques, area, volume, fundamental theorem

**The course 1B** from series and integration to differential equations

- Integration: parts, trig substitution, partial fractions, indefinite
- Series: convergence, Power, Taylor and Dirichlet series
- Differential equations: separation of variables, systems like exponential and logistic equations
- Systems diff eq: equilibria, nullclines, analysis

**The course 21A** geometry, extremization and integral theorems in space

- Geometry: analytic geometry of space, geometric objects, distances
- Differentiation: curves and surfaces, gradient, curl, divergence
- Integration: double and triple integrals, other coordinate systems
- Integral theorems: line and flux integrals, Green, Stokes and Gauss

**The course 21B** matrix algebra, eigensystems, dynamical systems and Fourier

- Equations and maps: Gauss-Jordan elimination, kernel, image, linear maps
- Matrix algebra: determinants, eigenvalues, eigenspaces, diagonalization
- Dynamical systems: difference and differential equations with various techniques
- Fourier theory: Fourier series and dynamical systems on function spaces

There is also a 19a/19b track. The 19a course focuses on models and applications in biology, the 19b course replaces differential equations from 21b with probability theory. The Math 20 course covers linear algebra and multivariable calculus for economists in one semester but covers less material than the 21a/21b track.

### The lighter side of calculus

Sofia, our bot had also to know a lot of jokes, especially about math. Here are some relevant to calculus in some way. I left out the inappropriate ones.

1. Why do you rarely find mathematicians at the beach? Because they use sine and cosine to get a tan.
2. **Theorem:** The less you know, the more you make. **Proof:** We know Power = Work/Time. Since Knowledge = Power and Time = Money we know Knowledge = Work/Money. Solve for Money to get Money = Work/Knowledge. If Knowledge goes to zero, money approaches infinity.
3. Why do they never serve beer in a calculus class? Because you can’t drink and derive.
5. If it’s zero degrees outside today. Tomorrow it will be twice as cold. How cold will it be?
6. There are three types of calculus teachers: those who can count and those who can not.
7. Calculus is like love; a simple idea, but it can be complicated.
8. A mathematician and an engineer are on a desert island with two palm trees and coconuts. The engineer climbs up, gets its coconut gets down and eats. The mathematician climbs up the other, gets the coconut, climbs the first tree and deposits it. “I’ve reduced the problem to a solved one”.
9. Pickup line: You are so $x^2$. Can I be $x^3/3$, the area under your curves?
10. **The Evolution of calculus teaching:**
   - 1960ies: A peasant sells a bag of potatoes for 10 dollars. His costs are 4/5 of his selling price. What is his profit?
   - 1970ies: A farmer sells a bag of potatoes for 10 dollars. His costs are 4/5 of his selling price, that is, 8 dollars. What is his profit?
   - 1980ies: A farmer exchanges a set P of potatoes with a set M of money. The cardinality of the set M is equal to 10, and each element of M is worth one dollars Draw ten big dots representing the elements of M. The set C of production costs is composed of two big dots less than the set M. Represent C as a subset of M and give the answer to the question: What is the cardinality of the set of profits?
   - 1990ies: A farmer sells a bag of potatoes for 10 dollars. His production costs are 8 dollars, and his profit is 2 dollars. Underline the word "potatoes" and discuss it with your classmates.
   - 2000ies: A farmer sells a bag of potatoes for 10 dollars. His or her production costs are 0.80 of his or her revenue. On your calculator, graph revenue vs. costs and run the program POTATO to determine the profit. Discuss the result with other students and start blog about other examples in economics.
   - 2010ies: A farmer sells a bag of potatoes for 10 dollars. His costs are 8 dollars. Use the Potato theorem to find the profit. Then watch the wobbling potato movie.
11. **Q:** What is the first derivative of a cow? **A:** Prime Rib!
12. **Q:** What does the zero say to the eight? **A:** Nice belt!
13. **Theorem.** A cat has nine tails. **Proof.** No cat has eight tails. Since one cat has one more tail than no cat, it must have nine tails.
14. **Q:** How can you tell that a mathematician is extroverted? **A:** When talking to you, he looks at your shoes instead of at his.
15. **Q:** What does the little mermaid wear? **A:** An algae-bra.
16. In a dark, narrow alley, a function and a differential operator meet: “Get out of my way - I’ll differentiate you till you’re zero!” “Try it - I’m e^x.” Same alley, same function, but a different operator: “Get out of my way - or I’ll differentiate you till you’re zero!” “Try it - I’m e^x.” “Too bad... I’m d/dy.”
17. **Q:** How do you make 1 burn? **A:** Fire differentiation at a log.
18. An investment firm hires. In the last round, a mathematician, an engineer, and a business guy are asked what starting salary expectations they had: mathematician: “Would 30,000 be too much?” engineer: “I think 60,000 would be OK.” Finance person: “What about 300,000?” Officer: “A mathematician will do the same work for a tenth!” Business guy: “I thought of 135,000 for me, 135,000 for you and 30,000 for the mathematician to do the work.
19. **Theorem.** Every natural number is interesting. **Proof.** Assume there is an uninteresting one. Then there is smallest one. But as the smallest, it is interesting. Contradiction!
Lecture 37: Calculus and the world

Last Lecture

Calculus and the world

There would have more to tell. One could make an entire course filled with applications of calculus. We have seen lectures on music, statistics, economics and computer science. Here are more ideas. It would be nice to have a few weeks to work them out. The number of applications explodes even more when doing multivariable calculus or linear algebra.

Calculus and Sports

Optimization and analysis of motion. Which path needs least energy? Calculus of motion in various sports.

Calculus and Biology

Exponential growth and decay. Populations grow exponentially. Radioactive particles decay fast.

Calculus and Physics

Chaos theory. How far into the future can we predict a system. Take a map an iterate it. Take a calculator and iterate.

Calculus and Art

We can use functions to generate new art forms using functions.

Calculus and Cosmology

How did the universe evolve. The Lorentz contraction. Is it realistic that we will ever meet an other civilisation.

Calculus and Medicine

Catastrophes happen also in our body. An example is the story of ”Period doubling” in the heart.

Calculus and Finance

The mathematics of Finance is complex and is done with stochastic differential equations, chaos theory and power law heuristics.

Related rates

Implicit differentiation and related rates are manifestations of the chain rule.

A) related rates: we have an equation \( F(x, y) = c \) relating two variables \( x, y \) which depend on time \( t \). Differentiate the equation with respect to \( t \) using the chain rule and solve for \( y' \).

B) implicit differentiation: we have an equation \( F(x, y(x)) = c \) relating \( y \) with \( x \). Differentiate the equation with respect to \( x \) using the chain rule and solve for \( y' \).

Examples:

A) \( x^2 + y^3 = 1 \), \( x(t) = \sin(t) \), then \( 3x^2 x' + 3y^2 y' = 0 \) so that \( y' = -x^2 x'/y^2 = -\sin^2(t) \cos(t)/(1 - \sin^2(t))^{1/3} \).

B) Same example but \( x(t) = x \): \( y' = -x^2/y^2 = -\sin^2(t)/(1 - \sin^3(t))^{1/3} \).

Substitution

Substitution replaces \( \int f(x) \, dx \) with \( \int g(u) \, du \) with \( u = u(x) \), \( du = u'(x) \, dx \). Special cases:

A) The antiderivative of \( f(x) = g(u(x))u'(x) \), is \( G(u(x)) \) where \( G \) is the antiderivative of \( g \).

B) \( \int f(ax + b) \, dx = F(ax + b)/a \) where \( F \) is the antiderivative of \( f \).

Examples:

A) \( \int \sin(x^3) x^4 \, dx = \int \sin(u) \, du/5 = -\cos(u)/5 + C = -\cos(x^3)/5 + C \).

B) \( \int \log(5x + 7) \, dx = \int \log(u) \, du/5 = (u \log(u) - u)/5 + C = (5x + 7) \log(5x + 7) - (5x + 7) + C \).

Integration by parts

A) Direct:

\[
\int x \sin(x) \, dx = x (-\cos(x)) - \int (-\cos(x)) \, dx = -x \cos(x) + \sin(x) + C \, dx .
\]

B) Tic-Tac-Toe: To integrate \( x^2 \sin(x) \):

| \( x^2 \) | \( \sin(x) \) |
| 2x | -\cos(x) |
| 2 | -\sin(x) |
| 0 | \cos(x) |

The anti-derivative is

\[-x^2 \cos(x) + 2x \sin(x) + 2 \cos(x) + C \, .\]

C) Merry go round: Example \( I = \int \sin(x)e^x \, dx \). Use parts twice and solve for \( I \).

Partial fractions

A) Make a common denominator on the right hand side \( \frac{1}{x(x-2)} = \frac{A(x-2) + B}{x(x-2)} \), and compare coefficients \( 1 = Ax - Ab + Bx - Ba \) to get \( A = B = 0 \), \( A - 2B = 1 \) and solve for \( A \), \( B \).

B) If \( f(x) = p(x)/(x - a)(x - b) \) with different \( a, b \), the coefficients \( A, B \) in \( \frac{Ax + B}{(x-a)(x-b)} \) can be obtained from

\[ A = \lim_{x \to a} f(x) = p(a)/(a - b), \quad B = \lim_{x \to b} f(x) = p(b)/(b - a) .\]

Examples:

A) \( \int \frac{1}{x^2 + 1} \, dx = \int \frac{A}{x^2 + 1} \, dx + \int \frac{B}{x^2 + 1} \, dx \). Find \( A, B \) by multiplying out and comparing coefficients in the nominator.

B) Directly write down \( A = 1 \) and \( B = -1 \), by plugging in \( x = -2 \) after multiplying with \( x - 2 \). or plugging in \( x = -1 \) after multiplying with \( x - 1 \).

Improper integrals

A) Integrate over infinite domain.

B) Integrate over singularity.

Examples:

A) \( \int_0^\infty 1/(x^2 + 1) \, dx = \arctan(\infty) - \arctan(0) = \pi/2 - 0 = \pi/2 \).

B) \( \int_0^3 1/x^{2/3} \, dx = (3/1)x^{1/3}|_0^3 = 3 \).

Trig substitutions

A) In places like \( \sqrt{1 - x^2} \), replace \( x \) by \( \cos(u) \).

B) Use \( u = \tan(x/2) \), \( dx = \frac{2}{1+z^2} \, du \), \( \sin(x) = \frac{2u}{1+u^2} \), \( \cos(x) = \frac{1-u^2}{1+u^2} \) to replace trig functions by polynomials.

Examples:

A) \( \int_0^1 \sqrt{1 - x^2} \, dx = \frac{\pi}{4} \). \( \cos(u) \, du = \int_{-\pi/2}^{\pi/2} (1 + \cos(2u))/2 = \frac{\pi}{2} \).

B) \( \int \frac{1}{\sqrt{1 + 2x - x^2}} \, dx = \int \frac{2}{\sqrt{1 - x^2}} \, dx = \log(u) + C = \log(\tan(\frac{x}{2}) + C \).

Applications, keywords to know

**Music:** hull function, piano function

**Economics:** average cost, marginal cost and total cost. Strawberry theorem, fit points

**Computer science:** curvature and Chaikin steps

**Statistics:** probability density function, cumulative distribution function, expectation, variance.

**Geometry:** area between two curves, volume of solid

**Numerical methods:** trapezoid rule, Simpson rule, Newton Method

**Psychology:** critical points and Catastrophes.

**Physics:** position, velocity and acceleration.

**Astronomy:** turn table to prevent wobbling, bottle calibration.

Apps to know

Since there are few questions on what has to be known about applications and definitions (this list only covers application parts):

- **Derivative**: Limit of differences $D_h f = [f(x + h) - f(x)]/h$ for $h \to 0$

- **Integral**: Limit of Riemann sums $S_h f = [f(0) + f(h) + ... f(kh)]/h$.

- **Newton step**: $T(x) = x - f(x)/f'(x)$.

- **Marginal cost**: the derivative $F'$ of the total cost $F$.

- **Average cost**: $F/x$ where $F$ is the total cost.

- **Velocity**: Derivative of the position.

- **Acceleration**: Derivative of the velocity.

- **Curvature**: $f''(x)/(1 + f'(x))^{3/2}$.

- **Probability distribution function**: nonnegative function with total $\int f(x)dx = 1$.

- **Cumulative distribution function**: anti-derivative of the probability distribution function.

- **Expectation**: $\int xf(x) \, dx$, where $f$ is the probability density function.

- **Piano function**: frequencies $f(k) = 440 \cdot 2^{k/12}$ for integer $k$.

- **Hull function**: The interpolation of local maxima.

- **Catastrophe**: A parameter $c$ at which a local minimum disappears.
Not on your fingertips

The following concepts have appeared but do not need to be learned by heart:

- **Entropy**: \( -\int f(x) \log(f(x)) \, dx \).
- **Moment of inertia**: \( \int x^2 f(x) \, dx \).
- **Monte Carlo integration**: \( S_n = \frac{1}{n} \sum_{k=1}^{n} f(x_k) \), where \( x_k \) are random in \([a, b]\).
- **Weierstrass function**: A function which is continuous but nowhere differentiable.
- **Bart Simpson rule**: \( S_n = \frac{1}{6n} \sum_{k=1}^{n} [f(x_k) + 4f(y_k) + f(x_{k+1})] \).
- **Chaikin step**: \( R_{2i} = \frac{3}{4} P_i + \frac{1}{4} P_{i+1}, \quad R_{2i+1} = \frac{1}{4} P_i + \frac{3}{4} P_{i+1} \).
- **Cocktail party stuff**: Eat, integrate and love, the story of exp in practice exam 2.
- **Bottles**: How to calibrate bottles. The calibration formula.
- **Sofia**: The name of a calculus bot.
- **Wobbly chair**: One can turn a chair on any lawn to stop it from wobbling.
- **Warthog**: "Tuk", the name of the warthog which appears in practice exam 2.
