A^{rev} \boxtimes M \in \text{A^{rev} \otimes A} \text{BMod}_{A^{rev}}(\C),
\]

and that the restriction of \( N \) to \( \Tens^\otimes_{\Delta^1 \{1\}} \) can be identified with \( M^{rev} \in \text{1BMod}_{A^{rev}}(\C) \). Consequently, \( N \) determines a map of bimodules

\[
\sigma_{A, 1, 1}(M) = A^\ast \otimes_{A^{rev} \otimes A} (A^{rev} \boxtimes M) \to M^{rev}.
\]

We will complete the proof by showing that this map is an equivalence: that is, that \( N \) is an operadic \( q \)-left Kan extension of the restriction \( N|_{\Tens^\otimes_{\Delta^1 \{0\}}} \). Let \( U_+ : N(\Delta^+)^{op} \to \Tens^\otimes \) be defined as in Notation 4.4.2.4. According to Proposition 4.4.2.5, it will suffice to verify that the composition \( N \circ U_+ : N(\Delta^+)^{op} \to \C^\otimes \) is an operadic \( q \)-coelim diagram.

Let \( u : N(\Delta^+)^{op} \to N(\Fin^\ast) \) denote the constant map taking the value \((1) \in N(\Fin^\ast) \). There is unique natural transformation \( \gamma : q \circ N \circ U_+ \to u \) which carries each object of \( N(\Delta^+)^{op} \) to an active morphism in
CHAPTER 4. ASSOCIATIVE ALGEBRAS AND THEIR MODULES

N(Fin∗). Choose a q-coCartesian natural transformation \( N \circ U \to B \) lifting \( \gamma \), so that \( B \) is an augmented simplicial object of the ∞-category \( \mathcal{C} \). Using Propositions 3.1.1.15 and 3.1.1.16, we are reduced to proving that \( B \) is a colimit diagram in \( \mathcal{C} \).

Let \( J \) denote the subcategory of \( \Delta \) whose objects have the form \([n]\) for \( n > 0 \) and whose morphisms are order-preserving maps \( \alpha : [m] \to [n] \) satisfying \( f(0) = 0 \) and \( f^{-1}\{m\} = \{n\} \). Let \( \text{Cut} : (\Delta)^{\text{op}} \to \text{Ass}^{\otimes} \) be as in Construction 4.1.2.5, given on objects by \( \text{Cut}([n]) = \{n\} \), and let \( \text{Cut}_0 = \text{Cut} | (\mathcal{J})^{\text{op}} \). We observe that \( \text{Cut}_0 \) lifts to a map \( \overline{\text{Cut}_0} : (\mathcal{J})^{\text{op}} \to \mathcal{C} \), given on objects by \( \overline{\text{Cut}_0}([n]) = (\{n\}, \{n\}) \). The functor \( \overline{\text{Cut}_0} \) carries each morphism in \( J \) to an active morphism in \( \mathcal{C}^{\otimes} \). Consequently, there is a natural transformation \( \delta \) from \( p' \circ \text{Cut}_0 \) to the constant functor \( (\mathcal{J})^{\text{op}} \to N(\mathcal{J}) \) taking the value \( (1) \), uniquely determined by the requirement that \( \delta \) carries each object of \( (\mathcal{J})^{\text{op}} \) to an active morphism in \( N(\mathcal{J}) \). Choose a q-coCartesian natural transformation \( \phi \circ \text{Cut}_0 \to B' \) of functors from \( (\mathcal{J})^{\text{op}} \) to \( \mathcal{C}^{\otimes} \), so that we can regard \( B' \) as a functor from \( (\mathcal{J})^{\text{op}} \) into \( \mathcal{C} \), given on objects by the formula \( B'([n]) = A^{\otimes n-1} \otimes M \).

Unwinding the definitions, we see that the functor \( B \) is equivalent to the composition

\[
N(\Delta^+)^{\text{op}} \xrightarrow{\epsilon} (\mathcal{J})^{\text{op}} \xrightarrow{B'} \mathcal{C},
\]

where \( \epsilon \) is induced by the functor \( \Delta^+ \to J \) given by \( I \mapsto [0] \ast \text{id}^{\text{op}} \ast I \ast [0] \). We are therefore reduced to proving that \( B' \circ \epsilon \) is a colimit diagram. This is clear, since \( \epsilon \) is a split augmented simplicial object of \( (\mathcal{J})^{\text{op}} \).

We conclude this section with a proof of Proposition 4.6.3.12. We use the same basic strategy as in our proof of Proposition 4.6.3.18, though the details are somewhat more tedious.

**Proof of Proposition 4.6.3.12.** We will construct an equivalence

\[
(A \boxtimes A^c \otimes_{A \boxtimes A^c} A) \simeq A;
\]

the existence of the other equivalence will then follow by symmetry. Our construction will depend functorially on \( A \) (though we can also deduce the functoriality by replacing \( \mathcal{C} \) by the functor category \( \text{Fun}(K, \mathcal{C}) \), where \( K = \text{Alg}(\mathcal{C}) \), and taking \( A \) to be the “universal” algebra object of \( \text{Fun}(K, \mathcal{C}) \)).

As in the proof of Proposition 4.6.3.18, we abuse notation by identifying \( \text{Fin}^* \) with the larger (but equivalent) category of all pointed finite sets, and make corresponding enlargements of the \( \infty \)-categories \( \text{Tens}^{\otimes} \) and \( \text{Ass}^{\otimes} \). We now define a functor \( f : \text{Tens}^{\otimes} \to \text{Ass}^{\otimes} \) as follows:

(a) When restricted to \( \text{Tens}^{\otimes} \times_{\Delta} \{1\} \simeq \mathcal{B}M^{\otimes} \), \( f \) agrees with the forgetful functor \( \mathcal{B}M^{\otimes} \to \text{Ass}^{\otimes} \) of Remark 4.3.1.8.

(b) Let \( X \) be an object of \( \text{Tens}^{\otimes} \times_{\Delta} \{0\} \), given by a finite pointed set \( S \) equipped with a pair of maps \( c_-, c_+ : S \to [2] \) (Write \( S \) as a disjoint union of subsets

\[
S_0 = \{ s \in S : c_-(s) = c_+(s) = 0 \} \quad S_1 = \{ s \in S : c_-(s) = c_+(s) = 1 \} \quad S_2 = \{ s \in S : c_-(s) = c_+(s) = 2 \} \;
\]

\[
S_{01} = \{ s \in S : 0 = c_-(s) < c_+(s) = 1 \} \quad S_{12} = \{ s \in S : 1 = c_-(s) < c_+(s) = 2 \}
\]

\( f(X) = I_* \), where \( I \) denotes the subset of \( S \times [8] \) given by the union of the subsets \( S_0 \times \{0\} \), \( S_{01} \times \{1\} \), \( S_1 \times \{2\} \), \( S_{12} \times \{3\} \), \( S_2 \times \{4\} \), \( S_{01} \times \{5\} \), \( S_1 \times \{6\} \), \( S_{12} \times \{7\} \), and \( S_2 \times \{8\} \).

(c) Let \( \alpha : (S_*, c_-, c_+) \to (S'_*, c'_-, c'_+) \) be a morphism in \( \text{Tens}^{\otimes} \times_{\Delta} \{0\} \), given by a map of finite pointed sets \( S \to S' \) (which we will also denote by \( \alpha \)) together with a linear ordering \( \preceq_{\alpha, s'} \) on each inverse image \( \alpha^{-1}\{s\} \). Let \( I \) and \( S_\xi \) (for \( \xi \in \{0,1,2,01,12\} \)) be defined as in (b), and define \( I' \) and \( S'_\xi \) similarly. We define a map of pointed finite sets \( f(\alpha) : I_* \to I'_* \) as follows:

\[
f(\alpha)(s, 0) = \begin{cases} 
(\alpha(s), 0) & \text{if } \alpha(s) \in S_0' \\
(\alpha(s), 1) & \text{if } \alpha(s) \in S_{01}' \\
* & \text{if } \alpha(s) = *
\end{cases}
\]
4.6. DUALITY

\[ f(\alpha)(s, 1) = \begin{cases} (\alpha(s), 1) & \text{if } \alpha(s) \in S'_{01} \\ * & \text{if } \alpha(s) = * \end{cases} \]

\[ f(\alpha)(s, 2) = \begin{cases} (\alpha(s), 1) & \text{if } \alpha(s) \in S'_{01} \\ (\alpha(s), 2) & \text{if } \alpha(s) \in S'_1 \\ (\alpha(s), 3) & \text{if } \alpha(s) \in S'_1' \\ * & \text{if } \alpha(s) = * \end{cases} \]

\[ f(\alpha)(s, 3) = \begin{cases} (\alpha(s), 3) & \text{if } \alpha(s) \in S'_1' \\ * & \text{if } \alpha(s) = * \end{cases} \]

\[ f(\alpha)(s, 4) = \begin{cases} (\alpha(s), 3) & \text{if } \alpha(s) \in S'_1' \\ (\alpha(s), 4) & \text{if } \alpha(s) \in S'_1 \\ (\alpha(s), 5) & \text{if } \alpha(s) \in S'_{01} \\ * & \text{if } \alpha(s) = * \end{cases} \]

\[ f(\alpha)(s, 5) = \begin{cases} (\alpha(s), 5) & \text{if } \alpha(s) \in S'_{01} \\ * & \text{if } \alpha(s) = * \end{cases} \]

\[ f(\alpha)(s, 6) = \begin{cases} (\alpha(s), 5) & \text{if } \alpha(s) \in S'_{01} \\ (\alpha(s), 6) & \text{if } \alpha(s) \in S'_1 \\ (\alpha(s), 7) & \text{if } \alpha(s) \in S'_1' \\ * & \text{if } \alpha(s) = * \end{cases} \]

\[ f(\alpha)(s, 7) = \begin{cases} (\alpha(s), 7) & \text{if } \alpha(s) \in S'_1' \\ * & \text{if } \alpha(s) = * \end{cases} \]

\[ f(\alpha)(s, 8) = \begin{cases} (\alpha(s), 7) & \text{if } \alpha(s) \in S'_1' \\ (\alpha(s), 8) & \text{if } \alpha(s) \in S'_1 \\ * & \text{if } \alpha(s) = * \end{cases} \]

For each \((s', j) \in I'\), we define a linear ordering \(\preceq_{f(\alpha),(s', j)}\) on the inverse image \(f(\alpha)^{-1}\{s', j\}\) as follows: we have \((s_0, i_0) \preceq f(\alpha),(s', j) (s_1, i_1)\) if and only if one of the following conditions hold:

- We have \(i_0 = i_1 \in \{1, 3, 5, 7\}\) (in which case we automatically have \(s_0 = s_1\)).
- We have \(i_0 = i_1 \in \{0, 2, 6, 8\}\) and \(s_0 \preceq_1 s_1\).
- We have \(i_0 = i_1 = 4\) and \(s_0 \preceq_3 s_1\).

\((d)\) Let \(\alpha\) be a morphism in \(\text{Tens}^\circ\) from an object \((S_*, c_* c_+) \in \text{Tens}^\circ \times \Delta^1\{0\}\) to an object \((S'_*, c'_* c'_+) \in \text{Tens}^\circ \times \Delta^1\{1\}\), given by a map of finite pointed sets \(S_* \to S'_*\) (which we will also denote by \(\alpha\)) together with a linear ordering \(\preceq_{\alpha, s'}\) of \(\alpha^{-1}\{s'\}\) for each \(s' \in S'_*\). Let \(I'\) be defined as in \((b)\). As a map of pointed finite sets, \(f(\alpha)\) is given by the composite map

\[ I_* \to (S \times [8])_* \to S_* \xrightarrow{\alpha} S'_*. \]

For each \(s' \in S'_*\), we define a linear ordering \(\preceq_{f(\alpha), s'}\) on \(f(\alpha)^{-1}\{s'\}\) as in \((c)\).
Let \( p : \text{Tens}^\otimes \to N(\text{Fin}_*) \) and \( p' : \text{Ass}^\otimes \to N(\text{Fin}_*) \) denote the forgetful functors. We define a natural transformation \( \iota : p' \circ f \to p \) between functors \( \text{Tens}^\otimes \to N(\text{Fin}_*) \) as follows:

- On objects \( (S_*, c_-, c_+) \in \text{Tens}^\otimes \times \Delta^! \{1\} \), \( \iota \) is given by the identity map from \( S_* \) to itself.
- On objects \( (S_*, c_-, c_+) \in \text{Tens}^\otimes \times \Delta^! \{0\} \), \( \iota \) is given by the composite map
  \[
  I_* \mapsto (S \times [8])_* \to S_* ,
  \]
  where \( I \) is defined as in (b).

Let \( q : \mathcal{C}^\otimes \to N(\text{Fin}_*) \) exhibit \( \mathcal{C}^\otimes \) as a symmetric monoidal \( \infty \)-category, and let \( A \) be an algebra object of \( \mathcal{C} \). Then we can lift \( \iota \) to a \( q \)-coCartesian natural transformation \( A \circ f \to A' \) between functors from \( \text{Tens}^\otimes \to \mathcal{C}^\otimes \). Unwinding the definitions, we see that the restriction of \( A' \) to \( \text{Tens}^\otimes \times \Delta^! \{0\} \) encodes the pair of bimodules

\[
A \boxtimes A^c \in _{A}B\text{Mod}_{A \boxplus A^c} \quad A^c \boxtimes A \in A \boxplus A^c B\text{Mod}_{A}(\mathcal{C}),
\]

and that the restriction of \( A' \) to \( \text{Tens}^\otimes \times \Delta^! \{1\} \) gives the bimodule object of \( \mathcal{C} \) determined by \( A \) (regarded as a bimodule over itself). Consequently, \( A' \) determines a map of bimodules

\[
(A \boxtimes A^c) \otimes_{A \boxplus A^c} (A^c \boxtimes A) \to A.
\]

We will complete the proof by showing that this map is an equivalence: that is, the map \( A' \) is operadic \( q \)-left Kan extension of its restriction \( A' \mid (\text{Tens}^\otimes \times \Delta^! \{0\}) \). Let \( U_+ : N(\Delta_+)^{op} \to \text{Tens}^\otimes \) be defined as in Notation 4.4.2.4. According to Proposition 4.4.2.5, it will suffice to verify that the composition \( A' \circ U_+ : N(\Delta_+)^{op} \to \mathcal{C}^\otimes \) is an operadic \( q \)-colimit diagram.

Let \( u : N(\Delta_+)^{op} \to N(\text{Fin}_*) \) denote the constant map taking the value \( (1) \in N(\text{Fin}_*) \). There is unique natural transformation \( \gamma : q \circ A' \circ U_+ \to u \) which carries each object of \( N(\Delta_+)^{op} \) to an active morphism in \( N(\text{Fin}_*) \). Choose a \( q \)-coCartesian natural transformation \( A' \circ U_+ \to B \) lifting \( \gamma \), so that \( B \) is an augmented simplicial object of the \( \infty \)-category \( \mathcal{C} \). Using Propositions 3.1.1.15 and 3.1.1.16, we are reduced to proving that \( B \) is a colimit diagram in \( \mathcal{C} \).

Let \( \mathcal{J} \) denote the subcategory of \( \Delta \) containing all objects, whose morphisms are order-preserving maps \( \alpha : [m] \to [n] \) satisfying \( f(0) = 0 \) and \( f(m) = n \). Let \( \text{Cut} : N(\mathcal{J})^{op} \to \text{Ass}^\otimes \) be as in Construction 4.1.2.5, and let \( \text{Cut}_0 = \text{Cut} \mid N(\mathcal{J})^{op} \). Then \( \text{Cut}_0 \) carries each morphism in \( \mathcal{J} \) to an active morphism in \( \text{Ass}^\otimes \). Consequently, there is a natural transformation \( \delta \) from \( p' \circ \text{Cut}_0 \) to the constant functor \( N(\mathcal{J})^{op} \to N(\text{Fin}_*) \) taking the value \( (1) \), uniquely determined by the requirement that \( \delta \) carries each object of \( N(\mathcal{J})^{op} \) to an active morphism in \( N(\text{Fin}_*) \). Choose a \( q \)-coCartesian natural transformation \( A \circ \text{Cut}_0 \to B' \) of functors from \( N(\mathcal{J})^{op} \to \mathcal{C}^\otimes \), so that we can regard \( B' \) as a functor from \( N(\mathcal{J})^{op} \) into \( \mathcal{C} \). Informally, \( B' \) is given by the formula \( B'([n]) = A^{\otimes n} \).

Unwinding the definitions, we see that the functor \( B \) is equivalent to the composition

\[
N(\Delta_+)^{op} \xrightarrow{\epsilon} N(\mathcal{J})^{op} \xrightarrow{B'} \mathcal{C},
\]

where \( \epsilon \) is induced by the functor \( \Delta_+ \to \mathcal{J} \) given by \( I \mapsto [0] \star I \star I^{op} \star I \star [0] \). We are therefore reduced to proving that \( B' \circ \epsilon \) is a colimit diagram.

Let \( \epsilon' : N(\Delta_+)^{op} \times N(\mathcal{J})^{op} \to N(\mathcal{J})^{op} \) be the functor induced by the formula \( (I, J) \mapsto [0] \star I \star I^{op} \star J \star [0] \), so that \( \epsilon' \) is given by composing \( \epsilon' \) with the diagonal map \( N(\Delta_+)^{op} \to N(\Delta_+)^{op} \times N(\Delta_+)^{op} \). Let \( \mathcal{X} \) denote the full subcategory of \( N(\Delta_+)^{op} \times N(\mathcal{J})^{op} \) spanned by those pairs \( ([i], [j]) \) where either \( i, j \geq 0 \), or \( i = j = -1 \). Then \( \mathcal{X} \simeq (N(\Delta \times \mathcal{J})^{op})^{\mathcal{C}} \). Since \( N(\mathcal{J})^{op} \) is sifted, \( B' \circ \epsilon \) is a colimit diagram if and only if \( B' \circ (\epsilon' | \mathcal{X}) \) is a colimit diagram.

Note that for each \( i \geq 0 \), the restriction of \( \epsilon' \) to \( \{[i]\} \times N(\Delta_+)^{op} \) extends to a split augmented simplicial object of \( N(\mathcal{J})^{op} \), so that \( B' \circ (\epsilon' | \{[i]\} \times N(\Delta_+)^{op}) \) is a colimit diagram in \( \mathcal{C} \). It follows that \( B' \circ (\epsilon' | N(\Delta)^{op} \times N(\mathcal{J})^{op}) \) is a left Kan extension of \( B' \circ (\epsilon' | N(\Delta)^{op} \times N(\mathcal{J})^{op}) \). Using Lemma T.4.3.2.7, we are reduced
to proving that the restriction $B' \circ \epsilon'((N(\Delta))^{op} \times N(\Delta_+)^{op})^\delta$ is a colimit diagram. Since the inclusion $N(\Delta)^{op} \times \{[-1]\} \hookrightarrow N(\Delta)^{op} \times N(\Delta_+)^{op}$ is left cofinal, we are reduced to proving that the restriction $B' \circ (\epsilon' N(\Delta_+)^{op} \times \{[-1]\})$ is a colimit diagram in $\mathcal{C}$. We now observe that this diagram is given by

$$I \mapsto B'((0 \ast I) \ast ([0] \ast I)^{op}),$$

and is therefore a split augmented simplicial object of $\mathcal{C}$. \qed

### 4.6.4 Smooth and Proper Algebras

Throughout this section, we fix a symmetric monoidal $\infty$-category $\mathcal{C}$ satisfying the following condition:

\begin{enumerate}
\item[(*)] The $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, and the tensor product functor $\otimes: \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects.
\end{enumerate}

Let $A$ be an algebra object of $\mathcal{C}$, and let $M$ be a left $A$-module. Then we can identify $M$ with an object of $\underline{\text{BMod}}_1(\mathcal{C})$, where $1$ denotes a unit algebra object of $\mathcal{C}$ (Corollary 4.3.2.8). In §4.6.2, we introduced two natural finiteness conditions on $M$:

\begin{enumerate}
\item[(a)] The condition that $M$ be a right dualizable object of $\underline{\text{BMod}}_1(\mathcal{C})$. According to Proposition 4.6.2.13, this condition is independent of the action of $A$ on $M$: it is equivalent to the requirement that $M$ be dualizable when viewed as an object of the symmetric monoidal $\infty$-category $\mathcal{C}$ (see §4.6.1).
\item[(b)] The condition that $M$ be a left dualizable object of $\underline{\text{BMod}}_1(\mathcal{C})$: that is, that $M$ admit an $A$-linear dual.
\end{enumerate}

In general, these conditions are not related to one another. For example, the object $A \in \underline{\text{LMod}}_A(\mathcal{C})$ is always left dualizable (Example 4.6.2.5), but is right dualizable if and only if $A$ is dualizable as an object of $\mathcal{C}$. In this section, we will introduce conditions on $A$ which guarantee that (a) implies (b) and vice-versa.

**Remark 4.6.4.1.** The finiteness conditions we introduce in this section are have been well-studied in the setting of differential graded algebras over a commutative ring. We refer the reader to [148] for an introduction.

**Definition 4.6.4.2.** Let $A$ be an algebra object of $\mathcal{C}$. We will say that $A$ is *proper* if it is dualizable when regarded as an object of $\mathcal{C}$.

**Remark 4.6.4.3.** Let $A$ be an algebra object of $\mathcal{C}$. The condition that $A$ is proper depends only on the image of $A$ under the forgetful functor $\underline{\text{Alg}}(\mathcal{C}) \to \mathcal{C}$. In particular, $A$ is proper if and only if the opposite algebra $A^{op}$ is proper.

The condition that an algebra object $A \in \underline{\text{Alg}}(\mathcal{C})$ be proper admits many characterizations:

**Proposition 4.6.4.4.** Let $A$ be an algebra object of $\mathcal{C}$. The following conditions are equivalent:

\begin{enumerate}
\item[(1)] The algebra object $A$ is proper.
\item[(2)] The coevaluation module $A^c \in \underline{\text{BMod}}_{A^{op} \otimes A}(\mathcal{C})$ is left dualizable.
\item[(3)] The evaluation module $A^e \in \underline{\text{BMod}}(\mathcal{C})$ is right dualizable.
\item[(4)] Let $B$ and $C$ be algebra objects of $\mathcal{C}$, and let $M \in \underline{\text{BMod}}(\mathcal{C})$ be left dualizable. Then $\sigma_{A,B,C}(M) \in \underline{\text{BMod}}(\mathcal{C})$ is also left dualizable, where $\sigma_{A,B,C}$ is defined as in Construction 4.6.3.9.
\item[(5)] Let $B$ and $C$ be algebra objects of $\mathcal{C}$, and let $N \in \underline{\text{BMod}}(\mathcal{C})$ be right dualizable. Then $\tau_{A,B,C}(N) \in \underline{\text{BMod}}(\mathcal{C})$ is right dualizable, where $\tau_{A,B,C}$ is defined as in Construction 4.6.3.9.
\end{enumerate}
(6) Let $B$ be an algebra object of $\mathcal{C}$, and let $M \in \text{LMod}_{A \otimes B}(\mathcal{C})$. If $M$ is left dualizable (that is, $M$ is left dualizable as an object of $A \otimes B \text{BMod}_1(\mathcal{C})$) then its image in $\text{LMod}_B(\mathcal{C}) \cong B \text{BMod}_1(\mathcal{C})$ is left dualizable.

(7) Let $C$ be an algebra object of $\mathcal{C}$, and let $N \in \text{RMod}_{A^{rev} \otimes C}(\mathcal{C})$. If $N$ is right dualizable (that is, if $N$ is right dualizable as an object of $1 \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$) then its image in $\text{RMod}_C(\mathcal{C}) \cong 1 \text{BMod}_C(\mathcal{C})$ is right dualizable.

(8) The forgetful functor $\text{LMod}_A(\mathcal{C}) \to \mathcal{C}$ carries (left) dualizable objects of $\text{LMod}_A(\mathcal{C})$ to dualizable objects of $\mathcal{C}$.

(9) The forgetful functor $\text{RMod}_{A^{rev}}(\mathcal{C}) \to \mathcal{C}$ carries (right) dualizable objects of $\text{RMod}_{A^{rev}}(\mathcal{C})$ to dualizable objects of $\mathcal{C}$.

Proof. We will show that $(1) \Rightarrow (2) \Rightarrow (4) \Rightarrow (6) \Rightarrow (8) \Rightarrow (1)$; the implications $(1) \Rightarrow (3) \Rightarrow (5) \Rightarrow (7) \Rightarrow (9)$ follow by the same argument. The implication $(1) \Rightarrow (2)$ follows from Proposition 4.6.2.13, the implication $(4) \Rightarrow (6)$ follows from Proposition 4.6.2.13 and Remark 4.6.3.10, the implication $(6) \Rightarrow (8)$ is obvious, and the implication $(8) \Rightarrow (1)$ follows from the observation that $A$ is left dualizable when viewed as an object of $\text{LMod}_A(\mathcal{C})$ (see Example 4.6.2.5). We will complete the proof by showing that $(2) \Rightarrow (4)$. Suppose that the coevaluation module $A^c$ is left dualizable, and let $M \in A \otimes B \text{BMod}_C(\mathcal{C})$ be left dualizable. Using Remark 4.6.3.5 and Example 4.6.2.15, we deduce that $A^c \boxtimes B \in B \text{BMod}_{A^{rev} \otimes A \otimes B}(\mathcal{C})$ and $A^{rev} \boxtimes M \in A^{rev} \otimes A \otimes B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$ are left dualizable, so that

$$\sigma_{A,B,C}(M) = (A^c \boxtimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \boxtimes M) \in B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$$

is left dualizable by Remark 4.6.2.6.

Suppose that $A \in \text{Alg}(\mathcal{C})$ is a proper algebra object. Let $A^\vee$ denote the dual of $A$, as an object of $\mathcal{C}$. Using Proposition 4.6.2.13, we see that the left action of $A$ on itself determines a right action of $A$ on $A^\vee$. Similarly, the right action of $A$ on itself determines a left action of $A$ on $A^\vee$. We will see in a second that these actions are compatible with one another: that is, $A^\vee$ has the structure of an $A$-bimodule object of $\mathcal{C}$.

**Definition 4.6.4.5.** Let $A$ be a proper algebra object of $\mathcal{C}$, so that the coevaluation module

$$A^c \in 1 \text{BMod}_{A^{rev} \otimes A}(\mathcal{C})$$

is left dualizable. We may then identify the left dual of $A^c$ with an object of $A^{rev} \otimes A \text{BMod}_1(\mathcal{C})$. We let $S_A$ denote the image of this object under the equivalence of $\infty$-categories

$$\sigma_{A^{rev},A,1} : A^{rev} \otimes A \text{BMod}_1(\mathcal{C}) \to A \text{BMod}_A(\mathcal{C})$$

of Construction 4.6.3.9. We will refer to $S_A$ as the **Serre bimodule** of $A$.

More explicitly, the Serre bimodule of a proper algebra $A$ is given by the tensor product

$$(A^c \boxtimes A) \otimes_{A \otimes A^{rev} \otimes A} (A \boxtimes A^{rev^*}),$$

where $A^{rev^*}$ denotes the left dual of $A^c$.

**Remark 4.6.4.6.** Let $A$ be a proper algebra object of $\mathcal{C}$, so that the opposite algebra $A^{rev}$ is also proper (Remark 4.6.4.3). Using Remark 4.6.3.8 and Proposition 4.6.3.15, we obtain a canonical equivalence $S_{A^{rev}} = (S_A)^{rev}$ in $A^{rev} \text{BMod}_{A^{rev}}(\mathcal{C})$. That is, the formation of Serre bimodules is compatible with reversal.

**Remark 4.6.4.7.** Let $A$ be a proper algebra object of $\mathcal{C}$. Then the left dual of the coevaluation bimodule $A^c$ is given by the relative tensor product

$$(S_A \boxtimes A^{rev}) \otimes_{A \otimes A^{rev}} A^c \in A \otimes A^{rev} \text{BMod}_1(\mathcal{C}) \cong A^{rev} \otimes A \text{BMod}_1(\mathcal{C}).$$
4.6. DUALITY

**Remark 4.6.4.8.** Let $A$ be a proper algebra object of $\mathcal{C}$. Then the evaluation module $A^e \in \mathcal{A} \otimes \mathcal{A}^{rev} \text{BMod}_1(\mathcal{C})$ is right dualizable. Let $S'_A$ denote the image of the right dual of $A^e$ under the equivalence of $\infty$-categories

$$\mathcal{BMod}_{A \otimes \mathcal{A}^{rev}}(\mathcal{C}) \simeq \mathcal{BMod}_{\mathcal{A}^{rev} \otimes A}(1) \mathcal{C}^{\tau_{\mathcal{A},A,A}} \text{BMod}_1(\mathcal{A}).$$

Note that the right dual of $A^e = (A^e)^{rev}$ can be identified with $M^{rev}$, where $M$ is the left dual of $A^e$. Using Remarks 4.6.3.17 and 4.6.4.6 we obtain equivalences $S'_A \simeq (S^e)^{rev} \simeq S_A$.

**Remark 4.6.4.9.** Let $A$ be a proper algebra object of $\mathcal{C}$, and let $S_A \in \mathcal{A} \text{BMod}_1(\mathcal{C})$ be its Serre bimodule. Using Remark 4.6.3.10 we see that the image of $S_A$ in $\text{LMod}_1(\mathcal{C})$ can be identified with the left dual of $A$, regarded as right module over itself. Using the alternative characterization of $S_A$ supplied by Remark 4.6.4.8, we can use the same reasoning to identify the image of $S_A$ under the forgetful functor $\mathcal{A} \text{BMod}_1(\mathcal{C}) \to \mathcal{RMod}_1(\mathcal{C})$ with the right dual of $A$, regarded as a left module over itself. More informally: we identify the Serre bimodule $S_A$ with the dual of $A$ (regarded as an object of $\mathcal{C}$), with a left action of $A$ induced by the right action of $A$ on itself, and a right action of $A$ induced by the left action of $A$ on itself.

**Remark 4.6.4.10.** Suppose we are given algebra objects $A,B,C \in \text{Alg}(\mathcal{C})$, where $A$ is proper, and let $M \in \mathcal{A} \otimes \mathcal{A} \text{BMod}_1(\mathcal{C})$ be left dualizable. According to Proposition 4.6.4.4, $\sigma_{A,B,C}(M) \in \text{BMod}_{A^\text{rev} \otimes C}(\mathcal{C})$ is also left dualizable. Let $M^*, A^*$, and $\sigma_{A,B,C}(M)^*$ denote the left duals of $M$ and $\sigma_{A,B,C}(M)$, respectively. Using the definition

$$\sigma_{A,B,C}(M) = (A^e \otimes B) \otimes A^{rev \otimes A \otimes B} (A^{rev} \otimes M)$$

and invoking Remark 4.6.2.6, we obtain an equivalence

$$\sigma_{A,B,C}(M)^* \simeq (A^{rev} \otimes M^*) \otimes A^{rev \otimes A \otimes B} (A^{rev} \otimes B) \otimes A^{rev \otimes A \otimes B} ((A^{rev})^e \otimes B)$$

$$\simeq (A^{rev} \otimes (M^* \otimes A \otimes B (S_A \otimes B))) \otimes A^{rev \otimes A \otimes B} ((A^{rev})^e \otimes B)$$

$$\simeq \tau_{A^{rev},C,B}(M^* \otimes A \otimes B (S_A \otimes B)).$$

**Example 4.6.4.11.** Let $A$ be a proper algebra object of $\mathcal{C}$, and let $M \in \text{LMod}_1(\mathcal{C}) \simeq \text{A} \text{BMod}_1(\mathcal{C})$. Note that Proposition 4.6.3.18 supplies an equivalence $M^{rev} \simeq \sigma_{A,1,1}(M)$. If $M$ is left dualizable, then $M^{rev}$ is also left dualizable. Let us denote their left duals by $\vee M$ and $\vee M^{rev}$. In this case, $M$ is also right dualizable, with right dual given by $(\vee M^{rev})^{rev}$. Remark 4.6.4.10 supplies an equivalence $\vee M^{rev} \simeq (M^* \otimes A S_A)^{rev}$, so that the right dual of $M$ can be identified with $\vee M \otimes A S_A$ as an object of $\mathcal{RMod}_A(\mathcal{C})$.

We next consider a finiteness condition on algebra objects which is in some sense dual to Definition 4.6.4.2.

**Proposition 4.6.4.12.** Let $A$ be an algebra object of $\mathcal{C}$. The following conditions are equivalent:

1. The coevaluation module $A^e \in \mathcal{BMod}_{A^{rev} \otimes A}(\mathcal{C})$ is right dualizable.
2. The evaluation module $A^{e} \in \mathcal{A} \otimes \mathcal{A}^{rev} \mathcal{BMod}_1(\mathcal{C})$ is left dualizable.
3. Let $B$ and $C$ be algebra objects of $\mathcal{C}$, and let $M \in \mathcal{A} \otimes \mathcal{B} \mathcal{BMod}_1(\mathcal{C})$ be right dualizable. Then $\sigma_{A,B,C}(M) \in \mathcal{BMod}_{A^{\text{rev}} \otimes C}(\mathcal{C})$ is also right dualizable, where $\sigma_{A,B,C}$ is defined as in Construction 4.6.3.9.
4. Let $B$ and $C$ be algebra objects of $\mathcal{C}$, and let $N \in \mathcal{BMod}_{A^{\text{rev}} \otimes C}(\mathcal{C})$ be left dualizable. Then $\tau_{A,B,C}(N) \in \mathcal{A} \otimes \mathcal{B} \mathcal{BMod}_1(\mathcal{C})$ is left dualizable, where $\tau_{A,B,C}$ is defined as in Construction 4.6.3.9.
5. Let $C$ be an algebra object of $\mathcal{C}$, and let $N \in \mathcal{RMod}_{A^{\text{rev}} \otimes C}(\mathcal{C})$. If the image of $N$ in $\mathcal{RMod}_C(\mathcal{C})$ is right dualizable, then $N$ is right dualizable.
6. Let $B$ be an algebra object of $\mathcal{C}$, and let $M \in \mathcal{LMod}_{\mathcal{A} \otimes \mathcal{B}}(\mathcal{C})$. If the image of $M$ in $\mathcal{LMod}_B(\mathcal{C})$ is left dualizable, then $M$ is left dualizable.
Proof. The equivalence of (1) and (2) is clear (since $A^e = (A^e)^{rev}$ by definition). We will show that (1) $\Rightarrow$ (3) $\Rightarrow$ (5) $\Rightarrow$ (1); the same argument will show that (2) $\Rightarrow$ (4) $\Rightarrow$ (6) $\Rightarrow$ (2).

Suppose first that (1) is satisfied, so that $A^e$ is right dualizable. Let $M \in A \otimes B B Mod_{\mathcal{C}}(\mathcal{C})$ be right dualizable. Using Remark 4.6.3.5 and Example 4.6.2.15, we deduce that $A^e \otimes B \in B B Mod_{A^{rev} \otimes A \otimes B}(\mathcal{C})$ and $A^{rev} \otimes M \in A^{rev} \otimes A \otimes B B Mod_{A^{rev} \otimes B}(\mathcal{C})$ are right dualizable, so that

$$\sigma_{A,B,C}(M) = (A^e \otimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \otimes M) \in B B Mod_{A^{rev} \otimes B}(\mathcal{C})$$

is right dualizable by Remark 4.6.2.6. This proves (3).

The implication (3) $\Rightarrow$ (5) follows from Proposition 4.6.2.13 and Remark 4.6.3.10 (take $B = 1$). Now suppose that (5) is satisfied; we wish to show that the coevaluation module $A^e$ is a right dualizable object of $1 B Mod_{A^{rev} \otimes A}(\mathcal{C})$. Using (5), we are reduced to showing that the image of $A^e$ in $1 B Mod_{A}(\mathcal{C})$ is right dualizable: that is, that $A$ is dualizable when viewed as a right module over itself. This follows from Example 4.6.2.5.

Definition 4.6.4.13. Let $A$ be an algebra object of $\mathcal{C}$. We will say that $A$ is smooth if the equivalent conditions of Proposition 4.6.4.12 are satisfied.

Remark 4.6.4.14. The terminology introduced in Definitions 4.6.4.2 and 4.6.4.13 is motivated by algebraic geometry. Let $\kappa$ be a field. The collection of chain complexes of vector spaces over $\kappa$ can be organized into an $\infty$-category (see §1.3.1) which we will denote by dVect$_{\kappa}$. Tensor product over $\kappa$ endows dVect$_{\kappa}$ with a symmetric monoidal structure (Proposition 7.1.2.11). Let $X$ be a quasi-projective variety defined over a field $\kappa$. Then the collection of complexes of quasi-coherent sheaves on $X$ can be organized into a stable $\infty$-category, which we will denote by QCoh(X). One can show that the $\infty$-category QCoh(X) always has the form LMod$_{\mathbb{A}}$(dVect$_{\kappa}$), where $\mathbb{A}$ is an associative algebra object of dVect$_{\kappa}$ (for example, if $X$ is an affine variety, we can take $\mathbb{A}$ to be the ring of functions on $X$). One can show that $\mathbb{A}$ is proper (in the sense of Definition 4.6.4.2) if and only if the variety $X$ is proper, and that $\mathbb{A}$ is smooth (in the sense of Definition 4.6.4.13) if and only if $X$ is smooth.

Remark 4.6.4.15. Let $A$ be an algebra object of $\mathcal{C}$. Then $A$ is smooth if and only if the opposite algebra $A^{rev}$ is smooth (this follows immediately from Remark 4.6.3.8).

Definition 4.6.4.16. Let $A$ be a smooth algebra object of $\mathcal{C}$, so that the coevaluation module

$$A^e \in 1 B Mod_{A^{rev} \otimes A}(\mathcal{C})$$

is right dualizable. We may then identify the right dual of $A^e$ with an object of $A^{rev} \otimes A B Mod_{1}(\mathcal{C})$. We let $T_A$ denote the image of this object under the equivalence of $\infty$-categories

$$\sigma_{A^{rev}, A, 1} : A^{rev} \otimes A B Mod_{1}(\mathcal{C}) \rightarrow A B Mod_{A}(\mathcal{C})$$

of Construction 4.6.3.9. We will refer to $T_A$ as the dual Serre bimodule of $A$.

Remark 4.6.4.17. Let $A$ be a smooth algebra object of $\mathcal{C}$, so that the opposite algebra $A^{rev}$ is also smooth. Using Remark 4.6.3.8 and Proposition 4.6.3.15, we obtain a canonical equivalence $T_{A^{rev}} \simeq (T_A)^{rev}$ in $A^{rev} B Mod_{A^{rev}}(\mathcal{C})$. That is, the formation of dual Serre bimodules is compatible with reversal.

Remark 4.6.4.18. Suppose we are given algebra objects $A, B, C \in \text{Alg}(\mathcal{C})$, where $A$ is smooth, and let $M \in A \otimes B B Mod_{C}(\mathcal{C})$ be right dualizable. Then the bimodule $\sigma_{A,B,C}(M) \in B B Mod_{A^{rev} \otimes C}(\mathcal{C})$ is also right dualizable. Let $M^*$ and $\sigma_{A,B,C}(M)^*$ denote the right duals of $M$ and $\sigma_{A,B,C}(M)$, respectively. Arguing as in Remark 4.6.4.10, we obtain a canonical equivalence

$$\sigma_{A,B,C}(M)^* \simeq \tau_{A^{rev}, C, B}(M^* \otimes_{A \otimes B} (S_A \otimes B)).$$
4.6. DUALITY

Example 4.6.4.19. Let $A$ be a smooth algebra object of $\mathcal{C}$, and let $M \in \text{LMod}_A(\mathcal{C})$ be a left $A$-module which is dualizable when regarded as an object of $\mathcal{C}$. According to Proposition 4.6.2.13, $M$ is right dualizable when regarded as an object of $\text{BMod}_A(\mathcal{C})$. Let us denote its right dual by $M^\vee \in \text{BMod}_A(\mathcal{C})$. Since $A$ is smooth, $M$ is also left dualizable. Moreover, the left dual of $M$ is given by $N^\text{rev}$, where $N$ is a right dual of $M^\text{rev} = \sigma_{A,1,1}(M)$. Using Remark 4.6.4.18, we see that the left dual of $M$ can be identified with $M^\vee \otimes_A T_A$, where $T_A$ is the dual Serre bimodule of Definition 4.6.4.16.

If $A \in \text{Alg}(\mathcal{C})$ is both smooth and proper, then the bimodules $S_A$ and $T_A$ are closely related:

Proposition 4.6.4.20. Let $A$ be an algebra object of $\mathcal{C}$ which is both smooth and proper. Then the bimodules $S_A, T_A \in \text{BMod}_A(\mathcal{C})$ are inverse to one another (as objects of the monoidal $\infty$-category $\text{BMod}_A(\mathcal{C})$). That is, we have equivalences

$$S_A \otimes_A T_A \simeq A \simeq T_A \otimes_A S_A$$

in the $\infty$-category $\text{BMod}_A(\mathcal{C})$. In particular, $S_A$ and $T_A$ are invertible objects of $\text{BMod}_A(\mathcal{C})$.

Proof. Since $A$ is smooth and proper, the evaluation and coevaluation modules $A^e$ and $A^c$ are both right dualizable. Let us denote their right duals by $A^{e*}$ and $A^{c*}$, respectively. Using Proposition 4.6.3.12 and Remark 4.6.2.6, we deduce that the tensor product $(A^{e*} \boxtimes A) \otimes_{A \otimes A^{\text{rev}}} (A \boxtimes A^{c*})$ is equivalent to $A$. Invoking the definitions (and Remark 4.6.4.8), we obtain equivalences

$$A^{e*} \simeq (A^{\text{rev}} \boxtimes A) \otimes_{A \otimes A^{\text{rev}}} (A^{\text{rev}})^c, \quad A^{c*} \simeq (A^{\text{rev}})^c \otimes_{A \otimes A^{\text{rev}}} (S_A \boxtimes A^{\text{rev}}).$$

We therefore obtain equivalences

$$A \simeq (A^{\text{rev}} \boxtimes A) \otimes_{A \otimes A^{\text{rev}}} (A \boxtimes A^{c*})$$
$$\simeq ((A^{\text{rev}})^c \boxtimes A) \otimes_{A \otimes A^{\text{rev}}} (S_A \boxtimes A \boxtimes A^{\text{rev}}) \otimes_{A \otimes A^{\text{rev}}} (A \boxtimes A^{\text{rev}})^c) \otimes_{A \otimes A^{\text{rev}}} T_A$$
$$\simeq T_A \otimes_A ((A^{\text{rev}})^c \boxtimes A) \otimes_{A \otimes A^{\text{rev}}} (A \boxtimes (A^{\text{rev}})^c) \otimes_A S_A$$
$$\simeq S_A \otimes_A T_A$$

in the $\infty$-category $\text{BMod}_A(\mathcal{C})$. The proof that $T_A \otimes_A S_A \simeq A$ is similar. □

Remark 4.6.4.21. If $\mathcal{C}$ is a symmetric monoidal $\infty$-category satisfying condition $(\ast)$, then we can organize the collection of algebra objects of $\mathcal{C}$ into a symmetric monoidal $(\infty,2)$-category, in which morphisms are given by bimodule objects of $\mathcal{C}$. The ideas of this section can be generalized: it makes sense to consider smooth and proper objects of an arbitrary symmetric monoidal $(\infty,2)$-category. For a brief account, we refer the reader to [98].

4.6.5 Frobenius Algebras

Throughout this section, we let $\mathcal{C}$ denote a monoidal $\infty$-category with unit object $1 \in \mathcal{C}$, satisfying the following condition:

$(\ast)$ The $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, and the tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects.

Assume for the moment that $\mathcal{C}$ is symmetric monoidal. In §4.6.4, we introduced the theory of smooth and proper algebra objects of $\mathcal{C}$. If $A \in \text{Alg}(\mathcal{C})$, then a left $A$-module $M \in \text{LMod}_A(\mathcal{C}) \simeq \text{BMod}_A(\mathcal{C})$ is left dualizable if and only if it is right dualizable. In this case, left and right duality generally gives two different objects $\text{rev}^A M, M' \in \text{RMod}_A(\mathcal{C})$. In this section, we will study additional structures on $A$, which allow us to identify $\text{rev}^A M$ with $M'$ as objects of $\mathcal{C}$.
Definition 4.6.5.1. Let $A \in \Alg(\mathcal{C})$ be an algebra object of $\mathcal{C}$, and let $m : A \otimes A \to A$ be the multiplication on $A$. We will say that a morphism $\lambda : A \to 1$ is nondegenerate if the composite map

$$A \otimes A \to A \xrightarrow{\lambda} 1$$

is a duality datum in $\mathcal{C}$.

A Frobenius algebra object of $\mathcal{C}$ is a pair $(A, \lambda)$, where $A$ is an algebra object of $\mathcal{C}$ and $\lambda : A \to 1$ is a nondegenerate map.

We will sometimes abuse terminology by using the term Frobenius algebra object to refer to an algebra object $A \in \mathcal{C}$ which admits a nondegenerate map $\lambda : A \to 1$. Our first result gives a characterization of such algebras:

Proposition 4.6.5.2. Let $A$ be an algebra object of $\mathcal{C}$. The following conditions are equivalent:

1. The algebra object $A$ can be promoted to a Frobenius algebra object of $\mathcal{C}$. That is, there exists a nondegenerate map $\lambda : A \to 1$.
2. As an object of $\RMod_A(\mathcal{C}) \simeq \BMod_A(\mathcal{C})$, $A$ is left dualizable. Moreover, its left dual $\vee A \in \BMod_A(\mathcal{C}) \simeq \LMod_A$ is equivalent to $A$, regarded as a left module over itself.
3. As an object of $\LMod_A(\mathcal{C}) \simeq \BMod_A(\mathcal{C})$, $A$ is right dualizable. Moreover, its right dual $A^\vee \in \BMod_A(\mathcal{C}) \simeq \RMod_A$ is equivalent to $A$, regarded a right module over itself.

Proof. We will show that (1) $\iff$ (2); the proof that (1) $\iff$ (3) is similar. Suppose first that (1) is satisfied. Let $M \in \BMod_A(\mathcal{C})$ and $N \in \BMod_A(\mathcal{C})$ denote the object $A$, regarded as a right or left module over itself, respectively. Then we can regard $\lambda$ as a map from $M \otimes_A N$ to $1$. Since $\lambda$ is nondegenerate, $A$ is left dualizable when regarded as an object of $\mathcal{C}$. It follows from Proposition 4.6.2.13 that $M$ admits a left dual $\vee M$, so that $\lambda$ classifies a map of left $\lambda$-modules $\theta : N \to \vee M$. The nondegeneracy of $\lambda$ guarantees that the image of $\theta$ in the $\infty$-category $\mathcal{C}$ is an equivalence. It follows that $\theta$ is an equivalence of left $A$-modules, so that $\lambda$ exhibits $N$ as a left dual of $M$. This proves (2).

Conversely, suppose that condition (2) is satisfied. Then $N$ is a left dual of $M$, so there exists a morphism $\lambda : M \otimes_A N \simeq A \to 1$. It follows from Remark 4.6.2.12 that $\lambda$ is nondegenerate.

Remark 4.6.5.3. Suppose that $\mathcal{C}$ is a symmetric monoidal $\infty$-category, and let $A$ be a proper algebra object of $\mathcal{C}$, with Serre bimodule $S_A \in \BMod_A(\mathcal{C})$ (see Definition 4.6.4.5). Using the proof of Proposition 4.6.5.2 and Remark 4.6.4.9, we obtain an equivalence between the following three types of data:

(a) Nondegenerate maps $\lambda : A \to 1$.

(b) Equivalences $S_A \simeq A$ in the $\infty$-category of left $A$-modules.

(c) Equivalences $S_A \simeq A$ in the $\infty$-category of right $A$-modules.

Remark 4.6.5.4. Suppose that $\mathcal{C}$ is a symmetric monoidal $\infty$-category, and let $A$ be a proper algebra object of $\mathcal{C}$ with Serre bimodule $S_A$. Let $\lambda : A \to 1$ be a morphism of $\mathcal{C}$, which is dual to a morphism $\lambda^\vee : 1 \to S_A$. Then $\lambda$ is nondegenerate if and only if it exhibits $S_A$ as a free right $A$-module generated by $1$. In this case, we can identify $S_A$ with an object of the fiber product $\BMod_A(\mathcal{C}) \times_{\RMod_A(\mathcal{C})} \{A\}$. Using Corollary 4.8.5.6, we deduce the existence of a morphism $\sigma_A : A \to A$ in $\Alg(\mathcal{C})$ with the following property: the Serre bimodule $S_A$ is equivalent in $\BMod_A(\mathcal{C})$ to $A$, where the right action of $A$ on itself is the evident one, and the left action of $A$ is via the morphism $\sigma_A$. Since the morphism $\lambda^\vee$ also exhibits $S_A$ as the free left $A$-module generated by $1$, we conclude that $\sigma_A : A \to A$ is an equivalence of left $A$-modules, and therefore an equivalence of algebra objects of $\mathcal{C}$. In this case, we will refer to $\sigma_A$ as the Serre automorphism of $A$. 

Warning 4.6.5.5. The terminology of Remark 4.6.5.4 is somewhat abusive: if \((A, \lambda)\) is a Frobenius algebra object of a symmetric monoidal \(\infty\)-category \(\mathcal{C}\), then the Serre automorphism \(\sigma_\lambda\) depends not only on \(A\), but also on \(\lambda\). However, the conjugacy class of \(\sigma_\lambda\) (in the automorphism group \(\pi_0 \text{Map}_{\text{Alg}(\mathcal{C})}(A, A)\)) is independent of \(\lambda\).

Remark 4.6.5.6. Assume that \(\mathcal{C}\) is symmetric monoidal, let \((A, \lambda)\) be a Frobenius algebra object of \(\mathcal{C}\), and let \(\sigma_\lambda : A \to A\) be the Serre automorphism of Remark 4.6.5.4. Let \(m_0 : A \otimes A \to A\) denote the multiplication on \(A\), and let \(m_1 : A \otimes A \to A\) denote the multiplication on the opposite algebra \(A^{\text{rev}}\). Unwinding the definitions, we deduce that the diagram

\[
\begin{array}{ccc}
A \otimes A & \xrightarrow{\text{id} \otimes \sigma_\lambda} & A \otimes A \\
\downarrow m_1 & & \downarrow m_0 \\
A & \xrightarrow{\lambda} & A \\
\downarrow \lambda & & \downarrow \lambda \\
1 & & 1
\end{array}
\]

commutes up to homotopy (in the \(\infty\)-category \(\mathcal{C}\)). Moreover, the commutativity of this diagram characterizes \(\sigma_\lambda\) up to homotopy as a morphism in the underlying \(\infty\)-category \(\mathcal{C}\). We can summarize the situation more informally by writing the equation \(\lambda(ab) = \lambda(b\sigma_\lambda(a))\).

Remark 4.6.5.7. Let \(\mathcal{C}\) be a symmetric monoidal \(\infty\)-category, and let \((A, \lambda)\) be a Frobenius algebra object of \(A\). Then the Serre bimodule \(S_A\) is equivalent to \(A\) when viewed either as a left \(A\)-module or as a right \(A\)-module. However, \(S_A\) need not be equivalent to \(A\) as an \(A\)-bimodule unless the Serre automorphism \(\sigma_\lambda\) is homotopic to the identity (or, more generally, if \(\sigma_\lambda\) is homotopic to an inner automorphism of \(A\): see \S5.3.2).

Giving an identification of \(S_A\) with \(A\) as an object of \(A\text{-BMod}_{\mathcal{C}}\) is equivalent to identifying the evaluation module \(A^c \in \text{LMod}_{A \otimes A^{\text{rev}}} (\mathcal{C})\) of Construction 4.6.3.7 with the left dual of the coevaluation module \(A^c \in \text{RMod}_{A \otimes A^{\text{rev}}} (\mathcal{C})\). Such an identification is determined by a duality pairing

\[
\overline{\lambda} : A^c \otimes_{A \otimes A^{\text{rev}}} A^c \to 1
\]

having the property that the composite map

\[
A \simeq A^c \otimes_A A^c \to A^c \otimes_{A \otimes A^{\text{rev}}} A^c \xrightarrow{\overline{\lambda}} 1
\]

is nondegenerate. In this case, we will refer to the pair \((A, \overline{\lambda})\) as a symmetric Frobenius algebra object of \(A\). Equivalently, we can define a symmetric Frobenius algebra object of \(A\) to be a Frobenius algebra object \((A, \lambda)\) in \(\mathcal{C}\), together with a homotopy from \(\text{id}_A\) to the Serre automorphism \(\sigma_\lambda\) (in the \(\infty\)-category \(\mathcal{C}\)).

Warning 4.6.5.8. Assume that \(\mathcal{C}\) is symmetric monoidal, and let \((A, \lambda)\) be a Frobenius algebra object of \(\mathcal{C}\). If \((A, \lambda)\) can be promoted to a symmetric Frobenius algebra object of \(\mathcal{C}\), then the duality pairing

\[
\beta : A \otimes A \xrightarrow{m} A \xrightarrow{\overline{\lambda}} 1
\]

is symmetric (up to homotopy). The converse generally fails: by virtue of Remark 4.6.5.6, the symmetry of the pairing \(\beta\) is equivalent to the requirement that the Serre automorphism \(\sigma_\lambda\) is homotopic to \(\text{id}_A\) in the \(\infty\)-category \(\mathcal{C}\), which is generally weaker than the requirement that \(\sigma_\lambda\) is homotopic to \(\text{id}_A\) in the \(\infty\)-category \(\text{Alg}(\mathcal{C})\). However, the converse does hold in situations where the forgetful map \(\text{Map}_{\text{Alg}(\mathcal{C})}(A, A) \to \text{Map}_\mathcal{C}(A, A)\) is fully faithful: for example, if \(\mathcal{C}\) is equivalent to the nerve of an ordinary category.
Remark 4.6.5.9. Assume that \( \mathcal{C} \) is symmetric monoidal. The passage from \( A \) to \( A^c \otimes_{A \otimes A^{rev}} A^c \) determines a functor from \( \text{Alg}(\mathcal{C}) \) to \( \mathcal{C} \), which we refer to as the cyclic bar construction. In \( \S 5.5.3 \), we will see that this functor is given by the formation of topological chiral homology

\[
A \mapsto \int_{S^1} A
\]

over the circle (Theorem 5.5.3.11). It follows that the cyclic bar construction \( A^c \otimes_{A \otimes A^{rev}} A^c \) admits an action of the circle group \( S^1 \). In this situation, one can obtain a variant of the notion of symmetric Frobenius algebra by imposing the further demand that a map

\[
\bar{\lambda} : A^c \otimes_{A \otimes A^{rev}} A^c \to 1
\]

be \( S^1 \)-equivariant. This equivariance condition plays an important role in the classification of two-dimensional topological quantum field theories; see [98] for an informal discussion.

Remark 4.6.5.10. Assume that \( \mathcal{C} \) is symmetric monoidal, and let \( A \) be a commutative algebra object of \( \mathcal{C} \). Then the canonical map \( A \to A^c \otimes_{A \otimes A^{rev}} A^c \) admits a left homotopy inverse. It follows that every map \( \lambda : A \to 1 \) factors (up to homotopy) through the cyclic bar construction, so that every Frobenius algebra structure on \( A \) can be promoted to a symmetric Frobenius algebra structure. In particular, for every nondegenerate map \( \lambda : A \to 1 \), the Serre automorphism \( \sigma_\lambda \) of Remark 4.6.5.6 is homotopic to the identity.

Assume that \( \mathcal{C} \) is symmetric monoidal, and let \( A \) be a proper algebra object of \( \mathcal{C} \). Then every left dualizable object \( M \in \text{LMod}_A(\mathcal{C}) \cong \text{AMod}_1(\mathcal{C}) \) is also right dualizable. According to Example 4.6.4.11, the left and right duals of \( M \) are related by the formula \( M^\vee = \gamma M \otimes_A S_A \). If there exists a nondegenerate map \( \lambda : A \to 1 \), then \( S_A \) is equivalent to \( A \) as a left \( A \)-module, so that we can identify \( M^\vee \) with \( \gamma M \) as objects of \( \mathcal{C} \). In fact, this identification does not require the tensor product on \( \mathcal{C} \) to be commutative:

**Proposition 4.6.5.11.** Let \( (A, \lambda) \) be a Frobenius algebra object of \( \mathcal{C} \), and suppose we are given \( A \)-modules \( M \in \text{LMod}_A(\mathcal{C}) \cong \text{AMod}_1(\mathcal{C}) \) and \( N \in \text{RMod}_A(\mathcal{C}) \cong \text{BMod}_1(\mathcal{C}) \), having images \( \overline{M}, \overline{N} \in \mathcal{C} \). Let \( e : M \otimes N \to A \) be a morphism in \( \text{AMod}_A(\mathcal{C}) \) which exhibits \( M \) as a right dual of \( N \). Then the composite map

\[
\overline{M} \otimes \overline{N} \xrightarrow{\xi} A \xrightarrow{\lambda} 1
\]

exhibits \( \overline{M} \) as a right dual of \( \overline{N} \) in the \( \infty \)-category \( \mathcal{C} \).

The proof of Proposition 4.6.5.11 is based on the following observation:

**Lemma 4.6.5.12.** Let \( A \) be an algebra object of \( \mathcal{C} \) and let \( \lambda : A \to 1 \) be a morphism in \( \mathcal{C} \). The following conditions are equivalent:

(a) The map \( \lambda \) is nondegenerate.

(b) For every object \( X \in \text{LMod}_A(\mathcal{C}) \) and every object \( Y \in \mathcal{C} \), the composite map

\[
\text{Map}_{\text{LMod}_A(\mathcal{C})}(M, A \otimes N) \to \text{Map}_{\mathcal{C}}(M, A \otimes N) \xrightarrow{\lambda} \text{Map}_{\mathcal{C}}(M, N)
\]

is a homotopy equivalence.

**Proof.** Let \( X \in \text{RMod}_A(\mathcal{C}) \) and \( Y \in \text{LMod}_A(\mathcal{C}) \) denote the algebra \( A \), regarded respectively as a right and left module over itself. We can then identify \( \lambda \) with a map \( X \otimes_A Y \to A \). According to Proposition 4.6.2.18, condition (b) is equivalent to the requirement that \( \lambda \) exhibits \( X \) as a right dual of \( Y \), while condition (a) is equivalent to the assertion that the composite map

\[
A \otimes A = X \otimes Y \to X \otimes_A Y \xrightarrow{\lambda} 1
\]

exhibits \( A \) as a left dual of itself as an object of the monoidal \( \infty \)-category \( \mathcal{C} \). The equivalence of these conditions now follows from Remark 4.6.2.14. \( \square \)
4.6. DUALITY

Proof of Proposition 4.6.5.11. Fix objects $X, Y \in \mathcal{C}$. We wish to show that the right vertical composition in the diagram

$$
\begin{array}{c}
\text{Map}_{\mathcal{C}}(X, N \otimes_A (A \otimes Y)) \\
\downarrow \\
\text{Map}_{\text{LMod}_A(\mathcal{C})}(M \otimes X, M \otimes N \otimes_A (A \otimes Y)) \\
\downarrow \\
\text{Map}_{\text{LMod}_A(\mathcal{C})}(M \otimes X, A \otimes Y) \\
\downarrow \theta \\
\text{Map}_{\mathcal{C}}(M \otimes X, Y).
\end{array}
$$

is a homotopy equivalence. The upper horizontal map is evidently a homotopy equivalence, and $\theta$ is a homotopy equivalence by Lemma 4.6.5.12. We are therefore reduced to showing that the left vertical composition is a homotopy equivalence, which follows from our assumption that $e$ is a duality datum.

\begin{remark}
Assume that $\mathcal{C}$ is a symmetric monoidal $\infty$-category, let $(A, \lambda)$ be a Frobenius algebra object of $\mathcal{C}$. Assume that further that the algebra object $A$ is smooth (Definition 4.6.4.13), and let $M \in \text{LMod}_A(\mathcal{C})$ be a left $A$-module whose image $M$ in $\mathcal{C}$ admits a dual $N$. Since $A$ is smooth, the dualizability of $M$ guarantees that $M$ is left dualizable (Proposition 4.6.4.12). Choose a morphism $e : M \otimes^\vee M \to A$ in $\text{ABMod}_A(\mathcal{C})$ which exhibits $M$ as a left dual of $M$. Then the composite map

$$
M \otimes^\vee M \to A \xrightarrow{\lambda} 1
$$

is classified by a map $M \to N$ in $\mathcal{C}$, which is an equivalence by Proposition 4.6.5.11. We may therefore identify $M$ with a preimage of $N$ under the forgetful functor $\text{RMod}_A(\mathcal{C})$.

We can summarize the situation as follows: if $(A, \lambda)$ is a smooth Frobenius algebra object of $\mathcal{C}$ and there exists a duality datum $e : M \otimes N \to 1$ in the $\infty$-category $\mathcal{C}$, then there exists a preimage $N$ of $N$ under the forgetful functor $\text{RMod}_A(\mathcal{C}) \to \mathcal{C}$, and a duality datum $e : M \otimes N \to A$ in $\text{ABMod}_A(\mathcal{C})$ such that $e$ is given by the composition

$$
\overline{M} \otimes \overline{N} \simeq M \otimes N \xrightarrow{e} A \xrightarrow{\lambda} 1.
$$

\begin{corollary}
Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category, let $A \in \text{CAlg}(\mathcal{C})$, and let $\lambda : A \to 1$ be a nondegenerate map. Let $M, N \in \text{Mod}_A(\mathcal{C})$, and let $e : M \otimes_A N \to A$ be a duality datum in the symmetric monoidal $\infty$-category $\text{Mod}_A(\mathcal{C})$. Then the composite map

$$
M \otimes N \to M \otimes_A N \xrightarrow{e} A \xrightarrow{\lambda} 1
$$

is a duality datum in $\mathcal{C}$.
\end{corollary}

\begin{proof}
Combine Proposition 4.6.2.19 with Proposition 4.6.5.11.
\end{proof}

\begin{remark}
In the situation of Corollary 4.6.4.9, suppose that $A$ is smooth, and that $M \in \text{Mod}_A(\mathcal{C})$ is dualizable as an object of $\mathcal{C}$. Using Propositions 4.6.2.19 and 4.6.4.12, we deduce that $M$ is also dualizable as an object of $\text{Mod}_A(\mathcal{C})$. It then follows from Corollary 4.6.5.14 that there exists a duality datum $e : M \otimes A N \to A$ in $\text{Mod}_A(\mathcal{C})$ for which the composite map

$$
M \otimes N \to M \otimes_A N \xrightarrow{e} A \xrightarrow{\lambda} 1
$$

is a duality datum in $\mathcal{C}$. We can informally summarize the situation by saying that if $A$ is a smooth commutative Frobenius object of $\mathcal{C}$, then the forgetful functor $\text{Mod}_A(\mathcal{C}) \to \mathcal{C}$ is compatible with duality.
\end{remark}
4.7 Monads and the Barr-Beck Theorem

Suppose we are given a pair of adjoint functors \( \mathcal{C} \leftarrow \mathcal{D} \xrightarrow{F} \mathcal{D} \xrightarrow{G} \mathcal{C} \) between ordinary categories. Then:

(A) The composition \( T = G \circ F \) has the structure of a monad on \( \mathcal{C} \); that is, an algebra object of the monoidal category \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) of endofunctors of \( \mathcal{C} \). Here the unit map \( \text{id}_\mathcal{C} \to T \) given by the unit of the adjunction between \( F \) and \( G \), and the product is given by the composition

\[
T \circ T = G \circ (F \circ G) \circ F \to G \circ \text{id}_\mathcal{C} \circ F = T
\]

where the second map is given by a compatible counit \( v \) for the adjunction between \( F \) and \( G \).

(B) For every object \( D \in \mathcal{D} \), the object \( G(D) \) has the structure of a module over the monad \( T \), given by the map \( TG(D) = ((G \circ F) \circ G)(D) = (G \circ (F \circ G))(D) \to G(D) \). This construction determines a functor \( \theta \) from \( \mathcal{D} \) to the category of \( T \)-modules in \( \mathcal{C} \).

(C) In many cases, the functor \( \theta \) is an equivalence of categories. The Barr-Beck theorem provides necessary and sufficient conditions on the functor \( G \) to guarantee that this is the case. We refer the reader to [99] for a detailed statement (or to Theorem 4.7.4.5 for our \( \infty \)-categorical version, which subsumes the classical statement).

Our goal in this section is to obtain \( \infty \)-categorical generalizations of assertions (A) through (C). We begin by observing that for any \( \infty \)-category \( \mathcal{C} \), composition and evaluation determines maps

\[
\text{Fun}(\mathcal{C}, \mathcal{C}) \times \text{Fun}(\mathcal{C}, \mathcal{C}) \to \text{Fun}(\mathcal{C}, \mathcal{C}) \quad \text{Fun}(\mathcal{C}, \mathcal{C}) \to \mathcal{C}
\]

which endow \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) with the structure of a simplicial monoid with a left action on the simplicial set \( \mathcal{C} \). In particular, we can regard \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) as monoidal \( \infty \)-category and \( \mathcal{C} \) as an \( \infty \)-category which is left-tensored over \( \text{Fun}(\mathcal{C}, \mathcal{C}) \). We will refer to the resulting monoidal structure on \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) as the composition monoidal structure.

**Definition 4.7.0.1.** Let \( \mathcal{C} \) be an \( \infty \)-category. A monad on \( \mathcal{C} \) is an algebra object of \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) (with respect to the composition monoidal structure). If \( T \) is a monad on \( \mathcal{C} \), we let \( L\text{Mod}_T(\mathcal{C}) \) denote the associated \( \infty \)-category of (left) \( T \)-modules in \( \mathcal{C} \).

**Remark 4.7.0.2.** More informally, a monad on an \( \infty \)-category \( \mathcal{C} \) consists of an endofunctor \( T : \mathcal{C} \to \mathcal{C} \) equipped with maps \( \text{id} \to T \) and \( T \circ T \to T \) which satisfy the usual unit and associativity conditions up to coherent homotopy. A \( T \)-module is then an object \( C \in \mathcal{C} \) equipped with a structure map \( T(C) \to C \) which is compatible with the algebra structure on \( T \), again up to coherent homotopy.

We can now state a preliminary version of the \( \infty \)-categorical Barr-Beck theorem.

**Theorem 4.7.0.3.** Suppose we are given a pair of adjoint functors

\[
\mathcal{C} \xrightarrow{F} \mathcal{D} \xleftarrow{G} \mathcal{C}
\]

between \( \infty \)-categories. Assume further that \( G \) is conservative, the \( \infty \)-category \( \mathcal{D} \) admits geometric realizations of simplicial objects, and \( G \) preserves geometric realizations of simplicial objects. Then there exists a monad \( T \) on \( \mathcal{C} \) and an equivalence \( G' : \mathcal{D} \simeq L\text{Mod}_T(\mathcal{C}) \) such that \( G \) is homotopic to the composition of \( G' \) with the forgetful functor \( L\text{Mod}_T(\mathcal{C}) \to \mathcal{C} \).

**Remark 4.7.0.4.** In the situation of Theorem 4.7.0.3, Proposition 4.2.4.2 implies that the image of \( T \) in \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) can be identified with the composition \( G \circ F \), and is therefore uniquely determined by \( G \). In fact, we will see in §4.7.4 that \( T \) is uniquely determined as an object of \( \text{Alg}(\text{Fun}(\mathcal{C}, \mathcal{C})) \).
4.7. MONADS AND THE BARR-BECK THEOREM

The proof of Theorem 4.7.0.3 breaks naturally into two parts:

(a) Constructing the monad \( T \) and a factorization of \( G \) as a composition \( \mathcal{D} \xrightarrow{G'} \text{LMod}_T(\mathcal{C}) \to \mathcal{C} \).

(b) Proving that the functor \( G' \) is an equivalence of \( \infty \)-categories.

In the classical setting, (a) is more or less immediate (the monad \( T \) is given by the composition \( G \circ F \)), and the multiplication on \( T \) is induced by a counit for the adjunction between \( G \) and \( F \). However, in the \( \infty \)-categorical setting we must work harder: to produce an algebra structure on the composition \( T = G \circ F \in \text{Fun}(\mathcal{C}, \mathcal{C}) \), it is not enough to produce a single natural transformation \( T \circ T \to T \): we must also supply an infinite hierarchy of coherence data, which is not so easy to explicitly describe.

We will therefore adopt a different strategy: rather than trying to construct the multiplication on \( T = G \circ F \) explicitly, we will instead characterize it by a universal property. Note that the monoidal \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) has a canonical left action on the \( \infty \)-category \( \text{Fun}(\mathcal{D}, \mathcal{C}) \). We will show that \( T \in \text{Fun}(\mathcal{C}, \mathcal{C}) \) can be identified with an endomorphism object of \( G \in \text{Fun}(\mathcal{D}, \mathcal{C}) \): that is, it is universal among those functors \( U \in \text{Fun}(\mathcal{C}, \mathcal{C}) \) which are equipped with a natural transformation \( U \circ G \to G \). In §4.7.4, we will formally deduce (in much greater generality) that \( T \) inherits the structure of an algebra object of \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) and that \( G \) inherits the structure of a left module over \( T \) (which supplies the desired factorization \( G' \)). The proof of these statements will require some auxiliary constructions which we discuss in §4.7.1.

Once the monad \( T \) and the functor \( G' : \mathcal{D} \to \text{LMod}_T(\mathcal{C}) \) have been constructed, we need to show that (under the hypotheses of Theorem 4.7.0.3) the functor \( G' \) is an equivalence of \( \infty \)-categories. In §4.7.4 we will prove a slightly stronger result: it is not necessary to assume that the functor \( G \) preserves geometric realizations of all simplicial objects in \( \mathcal{C} \). It is sufficient (and also necessary) that \( G \) preserves geometric realizations for the special class of \( G \)-split simplicial objects, which we study in §4.7.3.

The Barr-Beck theorem is an extremely useful result in higher category theory. For example, one can use it to deduce (in much greater generality) that \( T \) inherits the structure of an algebra object of \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) and that \( G \) inherits the structure of a left module over \( T \) (which supplies the desired factorization \( G' \)). The proof of these statements will require some auxiliary constructions which we discuss in §4.7.1.

### 4.7.1 Technical Digression: Simplicial Models for Planar \( \infty \)-Operads

Suppose we are given a coCartesian fibration of \( \infty \)-operads \( p : \mathcal{C}^\otimes \to \text{Ass}^\otimes \). According to Example 2.4.2.4, \( p \) is classified by an \( \text{Ass} \)-monoid object \( \chi : \text{Ass}^\otimes \to \text{Cat}_\infty \). Proposition 4.1.2.6 implies that \( \chi \) is determined (up to canonical equivalence) by the composite map

\[
\mathcal{N}(\Delta)^{op} \xrightarrow{\text{Cat}} \text{Ass}^\otimes \xrightarrow{\chi} \text{Cat}_\infty.
\]

This composite map classifies the coCartesian fibration \( \mathcal{C}^\otimes \simeq \mathcal{C}^\otimes \times_{\text{Ass}^\otimes} \mathcal{N}(\Delta)^{op} \to \mathcal{N}(\Delta)^{op} \). This suggests an alternative to Definition 4.1.1.10: we could instead define a monoidal \( \infty \)-category to be a coCartesian fibration \( \mathcal{C}^\otimes \to \mathcal{N}(\Delta)^{op} \) which is classified by a monoid object \( \mathcal{N}(\Delta)^{op} \to \text{Cat}_\infty \). Our goal in this section is to prove a generalization of this statement, which applies to an arbitrary fibration of \( \infty \)-operads \( \mathcal{C}^\otimes \to \text{Ass}^\otimes \).

We begin by recalling Notation 4.2.2.16: given a planar \( \infty \)-operad \( O^\otimes \to \text{Ass}^\otimes \), we let \( O^\otimes \) denote the fiber product \( \mathcal{N}(\Delta)^{op} \times_{\text{Ass}^\otimes} O^\otimes \). We say that a morphism in \( O^\otimes \) is inert if its image in \( O^\otimes \) is inert. We let \( O^\otimes,2 \) denote the marked simplicial set \( (O^\otimes, M) \), where \( M \) is the collection of inert morphisms in \( O^\otimes \). In particular, we let \( O^\otimes,2 \) denote the marked simplicial set \( (\mathcal{N}(\Delta)^{op}, M) \), where \( M \) is the collection of all morphisms \([m] \to [n] \) in \( \Delta \) which factor as a composition \([m] \simeq \{i, i+1, \ldots, i+m\} \to [n] \).

The main result of this section can be stated as follows:

**Proposition 4.7.1.1.** The construction \( \overline{X} \mapsto \overline{X} \times_{\text{Ass}^\otimes,1} \mathcal{N}(\Delta)^{op,2} \) determines a right Quillen equivalence \( (\mathcal{O}p_\infty)_{/\text{Ass}^\otimes,1} \to (\mathcal{O}p_\infty)_{/\mathcal{N}(\Delta)^{op,2}} \). Here \( \mathcal{O}p_\infty \) denotes the category of \( \infty \)-preoperads (see §2.1.4), endowed with the \( \infty \)-operadic model structure.
Remark 4.7.1.2. Proposition 4.1.2.6 implies that the map $N(\Delta)^{op,\otimes} \to \text{Ass}^{\otimes,\otimes}$ is a weak equivalence of $\infty$-preoperads. However, Proposition 4.7.1.1 does not follow formally from this, because $N(\Delta)^{op,\otimes}$ is not a fibrant object of $\mathcal{P}\mathcal{O}p{\infty}$ and the $\infty$-operadic model structure on $\mathcal{P}\mathcal{O}p{\infty}$ is not right proper.

Definition 4.7.1.3. Let $p : \mathcal{O}^\otimes \to N(\Delta)^{op}$ be a categorical fibration. We will say that a morphism $\alpha$ in $\mathcal{O}^\otimes$ is inert if it is $p$-coCartesian and $p(\alpha)$ is an inert morphism in $N(\Delta)^{op}$. Let $M$ be the collection of inert morphisms in $\mathcal{O}^\otimes$. We will say that $\mathcal{O}^\otimes \to N(\Delta)^{op}$ is a $\Delta$-planar $\infty$-operad if $(\mathcal{O}^\otimes, M)$ is a fibrant object of $(\mathcal{P}\mathcal{O}p{\infty})/N(\Delta)^{op,\otimes}$. In this case, we will refer to a morphism in $\mathcal{O}^\otimes$ as inert if it belongs to $M$. We will say that $p : \mathcal{O}^\otimes \to N(\Delta)^{op}$ is a $\Delta$-monoidal $\infty$-category if it is a $\Delta$-planar $\infty$-operad and the map $p$ is a coCartesian fibration.

Remark 4.7.1.4. If $(\mathcal{O}^\otimes, M)$ is any fibrant object of $(\mathcal{P}\mathcal{O}p{\infty})/N(\Delta)^{op,\otimes}$, then the underlying map $p : \mathcal{O}^\otimes \to N(\mathfrak{F}in{\ast})$ is a categorical fibration and $M$ is the collection of morphisms $\alpha$ of $\mathcal{O}^\otimes$ such that $p(\alpha)$ is inert and $\alpha$ is $p$-coCartesian (Remark 4.7.1.19). In other words, we can identify $\Delta$-planar $\infty$-operads with fibrant objects of $(\mathcal{P}\mathcal{O}p{\infty})/N(\Delta)^{op,\otimes}$.

Remark 4.7.1.5. We will obtain a more explicit description of the class of $\Delta$-planar $\infty$-operads below (see Definition 4.7.1.11 and Proposition 4.7.1.13).

Remark 4.7.1.6. The collection of $\Delta$-planar $\infty$-operads (planar $\infty$-operads) admits the structure of a simplicial category, where we define $\text{Map}(\mathcal{E}^\otimes, \mathcal{D}^\otimes)$ to be the subcategory of $\text{Fun}_{N(\Delta)^{op}}(\mathcal{C}^\otimes, \mathcal{D}^\otimes)$ spanned by those functors which preserve inert morphisms and those morphisms which are equivalences. It follows from Proposition 4.7.1.1 that the pullback functor

$$\mathcal{O}^\otimes \to N(\Delta)^{op} \times_{N(\mathfrak{F}in{\ast})} \mathcal{O}^\otimes$$

determines a weak equivalence from the simplicial category of planar $\infty$-operads to the simplicial category of $\Delta$-planar $\infty$-operads.

Definition 4.7.1.7. Let $\mathcal{E}^\otimes \to N(\Delta)^{op}$ be a $\Delta$-planar $\infty$-operad. We let $\Delta \text{Alg}(\mathcal{E})$ denote the full subcategory of $\text{Fun}_{N(\Delta)^{op}}(N(\Delta)^{op}, \mathcal{C}^\otimes)$ spanned by those functors which preserve inert morphisms.

Remark 4.7.1.8. The notation of Definition 4.7.1.7 is compatible with that of Definition 4.2.2.10 if the $\Delta$-planar $\infty$-operad $\mathcal{O}^\otimes$ is given by the fiber product $\mathcal{O}^\otimes \times_{\text{Ass}(\mathcal{O})} N(\Delta)^{op}$, for some planar $\infty$-operad $\mathcal{O}^\otimes$ (this can always be arranged after replacing $\mathcal{O}^\otimes$ by an equivalent $\Delta$-planar $\infty$-operad, by virtue of Proposition 4.7.1.1).

We will deduce Proposition 4.7.1.1 from a much more general assertion (Theorem 4.7.1.10). To formulate it, we need a bit of terminology.

Definition 4.7.1.9. Let $p : \mathcal{O}^\otimes \to N(\mathfrak{F}in{\ast})$ be an $\infty$-operad and let $f : \mathcal{E} \to \mathcal{O}^\otimes$ be an approximation to $\mathcal{O}^\otimes$. We will say that a morphism $\alpha$ in $\mathcal{E}$ is inert if $f(\alpha)$ is an inert morphism in $\mathcal{O}^\otimes$. We let $\mathcal{E}^\otimes$ denote the marked simplicial set $(\mathcal{E}, M)$, where $M$ is the collection of inert morphisms in $\mathcal{E}$. We will regard $(\mathcal{E}, M)$ as an $\infty$-preoperad via the composite map $p \circ f$.

We can now formulate the main result of this section (which immediately implies Proposition 4.7.1.1, by virtue of Proposition 4.1.2.10):

Theorem 4.7.1.10. Let $\mathcal{O}^\otimes$ be an $\infty$-operad and let $f : \mathcal{E} \to \mathcal{O}^\otimes$ be an approximation to $\mathcal{O}^\otimes$. Assume that $f$ induces an equivalence of $\infty$-categories $\mathcal{E} \times_{N(\mathfrak{F}in{\ast})}\{1\} \to \mathcal{O}$. Then composition with $f$ induces a left Quillen equivalence

$$\left(\mathcal{P}\mathcal{O}p{\infty}\right)/\mathcal{E}^\otimes \to \left(\mathcal{P}\mathcal{O}p{\infty}\right)/\mathcal{O}^\otimes.$$

Here $\mathcal{P}\mathcal{O}p{\infty}$ denotes the category of $\infty$-preoperads, endowed with the $\infty$-operadic model structure of Proposition 2.1.4.6.
4.7. MONADS AND THE BARR-BECK THEOREM

The proof of Theorem 4.7.1.10 will hinge on having a good characterization of the fibrant objects of $\mathcal{P}\text{Op}_{\infty}/\mathcal{E}^\oplus$.

**Definition 4.7.1.11.** Let $f : \mathcal{E} \to \mathcal{O}^\oplus$ be an approximation to an $\infty$-operad $p : \mathcal{O}^\oplus \to N(\text{Fin}_*)$, and let $q : \overline{\mathcal{E}} \to \mathcal{E}$ be a categorical fibration of simplicial sets. We will say that $q$ is *fibrous* if the following conditions are satisfied:

1. The map $q$ is an inner fibration.
2. For every object $E \in \overline{\mathcal{E}}$ and every inert morphism $\alpha : q(E) \to E'$, there exists a $q$-coCartesian morphism $\pi : E \to E'$ lifting $\alpha$.
3. Let $E \in \overline{\mathcal{E}}$, let $E = q(E)$, and let $(n) = (p \circ f)(E)$. For $1 \leq i \leq n$, choose an inert morphism $\alpha_i : E \to E_i$ in $\mathcal{E}$ covering $\rho^i : (n) \to (1)$, and a $q$-coCartesian morphism $\pi_i : E \to E_i$ in $\mathcal{E}$ covering $\alpha_i$.
   Then the morphisms $\pi_i$ exhibit $E$ as a $q$-product of the objects $\{E_i\}_{1 \leq i \leq n}$.
4. Let $E \in \mathcal{E}$, let $(n) = (p \circ f)(E)$, and choose inert morphisms $\alpha_i : E \to E_i$ in $\mathcal{E}$ covering the maps $\rho^i : (n) \to (1)$. Then the morphisms $\alpha_i$ induce an equivalence of $\infty$-categories $\overline{\mathcal{E}}_E \to \prod_{1 \leq i \leq n} \mathcal{E}_{E_i}$.

**Remark 4.7.1.12.** In the situation of Definition 4.7.1.11, conditions (1) and (2) imply that $q$ is a categorical fibration (Corollary T.2.4.6.5).

The key ingredient in the proof of Theorem 4.7.1.10 is the following result:

**Proposition 4.7.1.13.** Let $f : \mathcal{E} \to \mathcal{O}^\oplus$ be an approximation to an $\infty$-operad $p : \mathcal{O}^\oplus \to N(\text{Fin}_*)$, and let $q : \overline{\mathcal{E}} \to \mathcal{E}$ be a map of simplicial sets. The following conditions are equivalent:

(a) There exists a fibration of $\infty$-operads $\overline{\mathcal{O}}^\oplus \to \mathcal{O}^\oplus$ and a categorical equivalence $\mathcal{E} \to \mathcal{E} \times_{\mathcal{O}^\oplus} \overline{\mathcal{O}}^\oplus$ (compatible with $q$).

(b) There exists a collection of edges $M$ of $\overline{\mathcal{E}}$ such that $q$ induces a fibration of $\infty$-preoperads $(\overline{\mathcal{E}}, M) \to \mathcal{E}^\oplus$.

(c) The map $q$ is fibrous.

We will prove Proposition 4.7.1.13 at the end of this section.

**Proof of Theorem 4.7.1.10.** Let $f : \mathcal{E} \to \mathcal{O}^\oplus$ be an approximation to an $\infty$-operad $\mathcal{O}^\oplus$ which induces an equivalence $\mathcal{E} \times_{N(\text{Fin}_*)} \{1\} \to \mathcal{O}$. Let $F : (\mathcal{P}\text{Op}_{\infty})/\mathcal{E}^\oplus \to (\mathcal{P}\text{Op}_{\infty})/\mathcal{O}^\oplus$ be the functor given by composition with $f$, and let $G$ be its right adjoint (given by $X \mapsto \mathcal{E}^\oplus \times_{\mathcal{O}^\oplus} X$). We wish to show that the Quillen adjunction $(F, G)$ is a Quillen equivalence. The implication $(b) \Rightarrow (a)$ of Proposition 4.7.1.13 shows that the right derived functor $\mathcal{R}G$ is essentially surjective. It will therefore suffice to show that $\mathcal{R}G$ is right homotopy inverse to the left derived functor $\mathcal{L}F$. Unwinding the definitions, we must show that if $\overline{X}$ is a fibrant object of $(\mathcal{P}\text{Op}_{\infty})/\mathcal{O}^\oplus$, then the induced map $\mathcal{E}^\oplus \times_{\mathcal{O}^\oplus} \overline{X} \to \overline{X}$ is a weak equivalence of $\infty$-operads. Since $\overline{X}$ is fibrant, it has the form $\overline{\mathcal{O}}^\oplus$, where $\overline{\mathcal{O}}^\oplus \to \mathcal{O}^\oplus$ is a fibration of $\infty$-operads. Using Theorem 2.3.3.23, we are reduced to proving that the map $\mathcal{E} \times_{\mathcal{O}^\oplus} \overline{\mathcal{O}}^\oplus \to \overline{\mathcal{O}}^\oplus$ is an approximation to $\overline{\mathcal{O}}^\oplus$, which follows from Remark 2.3.3.9. \qed

**Variant 4.7.1.14.** Let $\gamma : N(\Delta)^{op} \times \Delta^1 \to \mathcal{L}\mathcal{M}^\oplus$ be the approximation to the $\infty$-operad $\mathcal{L}\mathcal{M}^\oplus$ described in Remark 4.2.2.8. The map $\gamma$ satisfies the hypotheses of Theorem 4.7.1.10, so that composition with $\gamma$ induces a left Quillen equivalence $(\mathcal{P}\text{Op}_{\infty})/(N(\Delta)^{op} \times \Delta^1)_{1} \to (\mathcal{P}\text{Op}_{\infty})/\mathcal{L}\mathcal{M}^\oplus_{1}$. Given a fibrant map $p : \mathcal{M}^\oplus \to N(\Delta)^{op} \times \Delta^1$, then $\mathcal{O}^\oplus = \mathcal{M}^\oplus \times_{\Delta^1} \{1\}$ is a $\Delta$-planar $\infty$-operad. We will denote the fiber $\mathcal{M}^\oplus \times_{N(\Delta)^{op} \times \Delta^1} \{([0], 0)\}$ by $\mathcal{M}$, and say that $p$ exhibits the $\infty$-category $\mathcal{M}$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{O}^\oplus$. If $p$ is a coCartesian fibration, then $\mathcal{O}^\oplus$ is a $\Delta$-monoidal $\infty$-category;
this case, we will say that \( p \) exhibits \( \mathcal{M} \) as left-tensored over the \( \Delta \)-monoidal \( \infty \)-category \( \mathcal{O}^\otimes \). Note that this terminology is consistent with that of Definitions 4.2.1.12 and 4.2.1.19.

Suppose that \( \mathcal{M}^\otimes \to \mathcal{N}(\Delta)^{op} \times \Delta^1 \) exhibits \( \mathcal{M} = \mathcal{M}^\otimes_{[0,1]} \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{O}^\otimes = \mathcal{M}^\otimes \times \Delta^1(1) \). We let \( \Delta \text{Mod}(\mathcal{M}) \) denote the full subcategory of \( \text{Fun}_{\mathcal{N}(\Delta)^{op} \times \Delta^1}(\mathcal{N}(\Delta)^{op} \times \Delta^1, \mathcal{M}^\otimes) \) spanned by those functors which preserve inert morphisms. There is an evident forgetful functor \( \Delta \text{Mod}(\mathcal{M}) \to \Delta \text{Alg}(\mathcal{E}) \). For each object \( A \in \Delta \text{Alg}(\mathcal{E}) \), we will denote the fiber product \( \Delta \text{Mod}(\mathcal{M}) \times_{\Delta \text{Alg}(\mathcal{E})} \{ A \} \) by \( \Delta \text{Mod}_A(\mathcal{M}) \). We note that these notations are consistent with those of Definition 4.2.2.10, in the case where \( \mathcal{O}^\otimes = \mathcal{O}^\otimes \times_{\text{LM}\mathcal{O}} (\mathcal{N}(\Delta)^{op} \times \Delta^1) \) for some fibration of \( \infty \)-operads \( \mathcal{O}^\otimes \to \mathcal{LM}\mathcal{O} \).

We now turn to the proof of Proposition 4.7.1.13. We will need a mild generalization of the construction of monoidal envelopes described in §2.2.4.

**Construction 4.7.1.15.** Let \( f : \mathcal{E} \to \mathcal{O}^\otimes \) be an approximation to an \( \mathcal{O}^\otimes \) and suppose we are given a fibrous map of simplicial sets \( q : \mathcal{T} \to \mathcal{E} \). We let \( \text{Env}_\mathcal{E}(\mathcal{T}) \) denote the full subcategory of \( \mathcal{T} \times_{\text{Fun}(\{0\}, \mathcal{T})} \text{Fun}(\Delta^1, \mathcal{E}) \) spanned by those pairs \((\mathcal{T}, \alpha) : q(\mathcal{T}) \to \mathcal{E}'\) such that \( f(\alpha) \) is an active morphism of \( \mathcal{O}^\otimes \). Evaluation at \( \{1\} \subseteq \Delta^1 \) determines a forgetful functor \( \text{Env}_\mathcal{E}(\mathcal{T}) \to \mathcal{E} \).

In the special case where \( \mathcal{E} \) is itself an \( \infty \)-operad, Construction 4.7.1.15 reduces to Construction 2.2.4.1. We now generalize a few of the properties established in §§2.2.4 to the present context.

**Lemma 4.7.1.16.** Let \( f : \mathcal{E} \to \mathcal{O}^\otimes \) be an approximation to an \( \mathcal{O}^\otimes \) and let \( q : \mathcal{T} \to \mathcal{E} \) be fibrous. Then the forgetful functor \( q' : \text{Env}_\mathcal{E}(\mathcal{T}) \to \mathcal{E} \) is a coCartesian fibration. Moreover, a morphism \( \alpha \in \text{Env}_\mathcal{E}(\mathcal{T}) \) is \( q' \)-coCartesian if and only if its image \( \alpha_0 \in \mathcal{T} \) is \( q \)-coCartesian and \( q(\alpha_0) \) is \( f \)-inert.

**Proof.** Note that evaluation at \( \{1\} \subseteq \Delta^1 \) induces a coCartesian fibration \( \mathcal{T} \times_{\text{Fun}(\{0\}, \mathcal{T})} \text{Fun}(\Delta^1, \mathcal{E}) \to \mathcal{E} \) (Corollary T.2.4.7.12). In view of Lemma 2.2.4.11 and Remark 2.2.4.12, it will suffice to show the following:

\[
(*) \text{ The inclusion } \text{Env}_\mathcal{E}(\mathcal{T}) \to \mathcal{T} \times_{\text{Fun}(\{0\}, \mathcal{T})} \text{Fun}(\Delta^1, \mathcal{E}) \text{ admits a left adjoint. Moreover, a morphism } \\
\alpha : X \to Y \text{ in } \mathcal{T} \times_{\text{Fun}(\{0\}, \mathcal{T})} \text{Fun}(\Delta^1, \mathcal{E}) \text{ exhibits } Y \text{ as an EnV}_\mathcal{E}(\mathcal{T})\text{-localization of } X \text{ if and only if } \\
Y \in \text{Env}_\mathcal{E}(\mathcal{T}), \text{ the image of } \alpha \text{ in } \mathcal{T} \text{ is } f\text{-inert, and the image of } \alpha \text{ in } \mathcal{E} \text{ is an equivalence.}
\]

According to Proposition 2.1.2.4, the \( f \)-active and \( f \)-inert morphisms determine a factorization system on \( \mathcal{E} \). Let \( \mathcal{A} \) be the full subcategory of \( \text{Fun}(\Delta^1, \mathcal{E}) \) spanned by the \( f \)-active morphisms. Lemma T.5.2.8.19 that the inclusion \( \mathcal{A} \subseteq \text{Fun}(\Delta^1, \mathcal{E}) \) admits a left adjoint, and that a morphism \( \alpha : g \to g' \) in \( \text{Fun}(\Delta^1, \mathcal{E}) \) corresponding to a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{u} & X' \\
\downarrow v & & \downarrow u' \\
Y & \xrightarrow{v'} & Y'
\end{array}
\]

in \( \mathcal{O}^\otimes \) exhibits \( g' \) as an \( \mathcal{A} \)-localization of \( v \) if and only if \( v' \) is \( f \)-active, \( u \) is \( f \)-inert, and \( u' \) is an equivalence. The desired result now follows from Lemma 2.2.4.13.

**Lemma 4.7.1.17.** Let \( f : \mathcal{E} \to \mathcal{O}^\otimes \) be an approximation to an \( \mathcal{O}^\otimes \) and let \( q : \mathcal{T} \to \mathcal{E} \) be fibrous. Suppose we are given an object \( E \in \mathcal{E} \) and a finite collection of \( f \)-inert morphisms \( \{ \alpha_a : E \to E_a \}_{a \in \mathcal{A}} \) with the following property: the maps \( \alpha_a \) lie over inert morphisms \( \langle n \rangle \to \langle n_a \rangle \) in \( \mathcal{F}\text{in}_\ast \) which determine a bijection \( \bigsqcup_a \langle n_a \rangle^\circ \to \langle n \rangle^\circ \). Then:

(a) For any collection of objects \( E_a \in \mathcal{T} \) lying over \( E_a \), there exists an object \( \overline{E} \in \mathcal{T} \) and a collection of morphisms \( \overline{\alpha}_a : \overline{E} \to E_a \) which exhibit \( \overline{E} \) as a \( q \)-product of the objects \( E_a \).

(b) For any object \( \overline{E} \in \mathcal{T} \) lifting \( E \) and any collection of morphisms \( \overline{\alpha}_a : \overline{E} \to \overline{E}_a \) lifting \( \alpha_a \), the morphisms \( \overline{\alpha}_a \) exhibit \( \overline{E} \) as a \( q \)-product of the objects \( E_a \) if and only if each \( \overline{\alpha}_a \) is \( q \)-coCartesian.
4.7. MONADS AND THE BARR-BECK THEOREM

Proof. We first prove (a). For $a \in A$ and $1 \leq i \leq n_a$, choose a locally $(p \circ f)$-coCartesian morphism $\beta_{a,i} : E_a \to E_{a,i}$ in $E$ covering the map $\rho' : \langle n_a \rangle \to \{1\}$ in $N(\Fin_a)$. These maps determine a map $u_a : K^a \to \xi$, where $K_a$ denotes the discrete simplicial set $\{1, \ldots, n_a\}$. Each $\beta_{a,i}$ can be lifted to a $q$-coCartesian morphism $\overline{E}_a \to \overline{E}_{a,i}$ in $\overline{E}$, and these liftings determine a diagram $\overline{\alpha}_a : K^a \to \xi$. Since $q$ is fibrous, each of the diagrams $\overline{\alpha}_a$ is a $q$-limit diagram.

Let $L = \coprod_{a \in A} K^a$, let $L_0$ be the full subcategory of $L$ spanned by the cone points of each $K^a$, and let $L_1$ be the full subcategory of $L$ given by $\coprod_{a \in A} K_a$. Let $u : L \to \overline{E}$ be the coproduct of the maps $u_a$ and let $\overline{\pi} : L \to \overline{E}$ be defined similarly; we note that $\overline{\pi}$ is a $q$-right Kan extension of $\overline{\pi}|L_1$. The maps $\alpha_a$ determine a diagram $v : L_0 \to \xi$. Since $L_0$ is left cofinal in $L$, we can amalgamate $u$ and $v$ to obtain a map $w : \xi \to \xi$. Using the assumption that $q$ is fibrous, we can lift $w$ to a diagram $\overline{\pi} : \xi \to \overline{E}$ which is a $q$-right Kan extension of $\overline{\pi}|L_1$. Since $\overline{\pi}$ is already a $q$-right Kan extension of $\overline{\pi}|L_1$, we may assume without loss of generality that $\overline{\pi}|L = \overline{\pi}$. Then $\overline{\pi}$ is a $q$-limit diagram. Since $L_0$ is right cofinal in $L$, it follows that $\overline{\pi}|L_0$ is a $q$-limit diagram, which proves (a).

The above argument shows that an arbitrary diagram $\overline{\pi} : L_0 \to \xi$ lifting $v$ (corresponding to a collection of morphisms $\overline{\alpha}_a : \overline{E} \to \overline{E}_{a,i}$) is a $q$-limit diagram if and only if, for every index $a \in A$ and $1 \leq i \leq n_a$, the composite map $\overline{\beta}_{a,i} \circ \overline{\alpha}_a : \overline{E} \to \overline{E}_{a,i}$ is $q$-coCartesian, where $\overline{\beta}_{a,i}$ is a $q$-coCartesian morphism $\overline{E}_a \to \overline{E}_{a,i}$ lifting $\beta_{a,i}$. To prove (b), we wish to show that each of the maps $\overline{\alpha}_a$ is $q$-coCartesian if and only if each of the compositions $\overline{\beta}_{a,i} \circ \overline{\alpha}_a$ is $q$-coCartesian. The “only if” direction is obvious. To prove the converse, let us suppose that each $\overline{\beta}_{a,i} \circ \overline{\alpha}_a$ is $q$-coCartesian. For each $a \in A$, we can factor $\overline{\alpha}_a$ as a composition

$$
\overline{E} \twoheadrightarrow \overline{E}_a \twoheadrightarrow \overline{E}_{a,i} \twoheadrightarrow \overline{E}_{a,i}
$$

where $\overline{\alpha}'_a$ is a $q$-coCartesian morphism lifting $\alpha_a$ and $\overline{\alpha}''_a$ is a morphism lifting the identity $\id_{E_a}$. Since $\overline{\alpha}'_a$ and $\overline{\beta}_{a,i} \circ \overline{\alpha}_a$ are $q$-coCartesian, we conclude that each composition $\overline{\beta}_{a,i} \circ \overline{\alpha}''_a$ is $q$-coCartesian. In other words, the functor $\overline{E}_{E_a} \to \overline{E}_{E_{a,i}}$ determined by $\beta_{a,i}$ carries $\overline{\alpha}''_a$ to an equivalence, for each $1 \leq i \leq n_a$. Since $q$ is fibrous, we have $\overline{E}_{E_a} \simeq \coprod_{1 \leq i \leq n_a} \overline{E}_{E_{a,i}}$; it follows that $\overline{\alpha}''_a$ is an equivalence, so that $\overline{\alpha}_a$ is $q$-coCartesian as desired.

Lemma 4.7.1.18. Let $f : \xi \to \mathcal{O}^\circ$ be an approximation to an infinite operad $p : \mathcal{O}^\circ \to N(\Fin_a)$ and let $q : \overline{E} \to \xi$ be fibrous. Then the coCartesian fibration $q' : \Env_\xi(\overline{E}) \to \xi$ of Lemma 4.7.1.16 is classified by a functor $\chi : \xi \to \mathsf{Cat}_{\infty}$ which belongs to $\Mod_\xi(\mathsf{Cat}_{\infty})$.

Proof. Fix an object $E \in \xi$ lying over $(n) \in N(\Fin_a)$, and choose locally $(p \circ f)$-coCartesian morphisms $\alpha_i : E \to E_i$ covering the maps $\rho_i : \langle n \rangle \to \{i\}$ for $1 \leq i \leq n$. Let $K = \{1, \ldots, n\}$, regarded as a discrete simplicial set, so that the maps $\alpha_i$ determine a diagram $u : K^\circ \to \xi$ carrying the cone point to the object $E$. Let $\chi(\overline{E})$ be the full subcategory of $\Fun(K^\circ, \Env_\xi(\overline{E})) \times_{\Fun(K^\circ, \xi)} \xi$ spanned by those functors $K^\circ \to \Env_\xi(\overline{E})$ lifting $u$ which carry each edge $\{i\}^\circ$ of $K^\circ$ to a $q'$-coCartesian morphism in $\Env_\xi(\overline{E})$. Proposition 4.3.2.15 implies that the restriction map $\theta : \chi(\overline{E}) \to \Env_\xi(\overline{E})_{E_i}$ is a trivial Kan fibration.

We wish to show that the coCartesian fibration $q'$ induces an equivalence of $\infty$-categories $\Env_\xi(\overline{E}) \to \prod_{1 \leq i \leq n} \Env_\xi(\overline{E})_{E_i}$. Unwinding the definitions, this map is given by composing a section of $\theta$ with the restriction map $\phi : \chi(\overline{E}) \to \chi_0(\overline{E})$, where

$$
\chi_0(\overline{E}) = \Fun(K, \Env_\xi(\overline{E})) \times_{\Fun(K, \xi)} \{E_1, \ldots, E_n\} \simeq \Env_\xi(\overline{E})_{E_1} \times \cdots \Env_\xi(\overline{E})_{E_n}.
$$

It will therefore suffice to show that $\phi$ is a trivial Kan fibration.

We begin by treating the case where $\overline{E} = \overline{E}$. We may assume without loss of generality that $f : \xi \to \mathcal{O}^\circ$ is a categorical fibration. In this case, Proposition 4.3.2.15 implies that composition with $f$ induces a trivial Kan fibration $\Env_\xi(\overline{E}) \to \xi \times_{\mathcal{O}^\circ} \Env_\xi(\mathcal{O}^\circ)$, and the desired result follows immediately from Proposition 2.2.4.4.

We now treat the general case. Note that $\phi$ factors as a composition

$$
\chi(\overline{E}) \twoheadrightarrow \chi(\overline{E}) \times_{\chi_0(\overline{E})} \chi_0(\overline{E}) \twoheadrightarrow \chi_0(\overline{E}).
$$
The special case treated above shows that \( \phi'' \) is a trivial Kan fibration. It will therefore suffice to show that \( \phi' \) is a trivial Kan fibration. This follows from Lemma 4.7.1.17 and Proposition T.4.3.2.15.

Proof of Proposition 4.7.1.13. We first show that (a) \( \Rightarrow \) (b). Suppose there exists a fibration of \( \infty \)-operads \( \phi: \overline{\mathcal{O}}^\otimes \to \mathcal{O}^\otimes \) and a categorical equivalence \( u: \overline{E} \to \mathcal{E} \times_{\mathcal{O}^\otimes} \overline{\mathcal{O}}^\otimes \). We wish to show that the map \( q: (\overline{E}, M) \to \mathcal{E}^i \) is a fibration of \( \infty \)-preoperads. Choose a trivial cofibration of \( \infty \)-preoperads \( i: (X, M_X) \to (Y, M_Y) \). We wish to show that every lifting problem

\[
\begin{array}{ccc}
(X, M_X) & \xrightarrow{v} & (\overline{E}, M) \\
\downarrow & & \downarrow q \\
(Y, M_Y) & \xrightarrow{u} & \mathcal{E}^i
\end{array}
\]

admits a solution. Since \( \overline{\mathcal{O}}^\otimes \to \mathcal{O}^\otimes \) is a fibration of \( \infty \)-preoperads, the composite map \( u \circ v \) can be extended to a map \( \phi: \mathcal{E} \times_{\mathcal{O}^\otimes} \overline{\mathcal{O}}^\otimes \) which carries every morphism in \( M_Y \) to an inert morphism in \( \overline{\mathcal{O}}^\otimes \). Applying Proposition T.A.2.3.1 (in the category \( \text{(Set}_\Delta)/\mathcal{E} \), equipped with the Joyal model structure) we can extend \( v \) to a map \( \overline{\tau}: \mathcal{E} \to \overline{\mathcal{E}} \) such that \( u \circ \overline{\tau} \) is homotopic to \( \phi \). It follows that \( \overline{\tau} \) carries each morphism in \( M_Y \) to a \( q \)-coCartesian morphism in \( \overline{\mathcal{E}} \) and therefore provides the desired solution.

We now prove that (b) \( \Rightarrow \) (c). Let \( \mathfrak{P}_\mathcal{E} \) denote the categorical pattern on \( \mathcal{E} \) given by \( (M, T, \{p_\alpha : \langle n \rangle^\otimes \to \mathcal{E}_\alpha\}_{\alpha \in A}) \) where \( M \) is the collection of all \( f \)-inert morphisms in \( \mathcal{E} \), \( T \) is the collection of all \( S \)-simplices in \( \mathcal{E} \), and \( A \) is the collection of all diagrams \( p_\alpha : \langle n \rangle^\otimes \to \mathcal{E} \) which carry the cone point of \( \langle n \rangle^\otimes \) to an object \( E \in \mathcal{E} \) lying over \( \langle n \rangle \in \text{N}(\mathfrak{F}_n) \) and carry each edge \( \langle \{i\}^\otimes \) to an \( f \)-inert morphism \( E \to E_i \) in \( \mathcal{E} \) lying over the map \( \rho': \langle n \rangle \to \langle 1 \rangle \). It now suffices to observe that \( q \) is fibrous if and only if it is \( \mathfrak{P}_\mathcal{E} \)-fibered, and that every \( \mathfrak{P} \)-anodyne map (see Definition B.1.1) determines a weak equivalence of \( \infty \)-preoperads.

We complete the proof by showing that (c) \( \Rightarrow \) (a). Assume that \( q: \overline{\mathcal{E}} \to \mathcal{E} \) is fibrous. Let \( q': \text{Env}_\mathcal{E}(\overline{E}) \to \mathcal{E} \) be the map given by Construction 4.7.1.15. Then \( q' \) is a coCartesian fibration (Lemma 4.7.1.16) and is classified by a map \( \chi: \mathcal{E} \to \text{Cat}_\infty \) which belongs to \( \text{Mon}_\mathcal{E}(\text{Cat}_\infty) \) (Lemma 4.7.1.18). Using Proposition 4.1.2.11, we may assume that \( \chi \) factors as a composition

\[
\mathcal{E} \xrightarrow{\theta} \mathcal{O}^\otimes \xrightarrow{\chi'} \text{Cat}_\infty,
\]

where \( \chi' \in \text{Mon}_\mathcal{O}(\text{Cat}_\infty) \). The map \( \chi' \) classifies a coCartesian fibration of \( \infty \)-operads \( \mathcal{E}^\otimes \to \mathcal{O}^\otimes \) and there is a categorical equivalence \( \theta: \text{Env}_\mathcal{E}(\mathcal{E}) \to \mathcal{E} \times_{\mathcal{O}^\otimes} \mathcal{E}^\otimes \). Let \( \text{Env}_\mathcal{E}(\mathcal{E}) \) denote the full subcategory of \( \mathcal{U}_\mathcal{E}(\mathcal{E}) \) spanned by those pairs \( (\mathcal{E}, \alpha : q(\mathcal{E}) \to \mathcal{E}') \) where \( \alpha \) is an equivalence, and let \( \mathcal{E}_0 \subseteq \mathcal{E} \) denote the essential image of \( \text{Env}_\mathcal{E}(\mathcal{E}) \times_{\text{N}(\mathfrak{F}_n)} \{\{1\}\} \) under the equivalence \( \text{Env}_\mathcal{E}(\mathcal{E}) \times_{\text{N}(\mathfrak{F}_n)} \{\{1\}\} \simeq \mathcal{E} \). Let \( \mathcal{E}_0^\otimes \) denote the full subcategory of \( \mathcal{E}^\otimes \) determined by \( \mathcal{E}_0 \subseteq \mathcal{E} \) (see the introduction to §2.2.1), so that we have a fibration of \( \infty \)-operads \( \mathcal{E}_0^\otimes \to \mathcal{O}^\otimes \). The functor \( \theta \) restricts to an equivalence of \( \infty \)-categories \( \text{Env}_\mathcal{E}(\mathcal{E}) \to \mathcal{E} \times_{\mathcal{O}^\otimes} \mathcal{E}_0^\otimes \). Composing with a section of the trivial Kan fibration \( \text{Env}_\mathcal{E}(\mathcal{E}) \to \mathcal{E} \), we obtain the desired categorical equivalence \( \mathcal{E} \to \mathcal{E} \times_{\mathcal{O}^\otimes} \mathcal{E}_0^\otimes \).

Remark 4.7.1.19. Suppose that \( q: \overline{\mathcal{E}} \to \mathcal{E} \) satisfies the equivalent conditions of Proposition 4.7.1.13. It follows from the proof that there is a unique collection morphisms \( M \) for which the map \( (\overline{E}, M) \to \mathcal{E}^i \) is a fibration: namely, the collection of morphisms \( \alpha \) such that \( \alpha \) is \( q \)-coCartesian and \( q(\alpha) \) is \( f \)-inert.

4.7.2 Endomorphism \( \infty \)-Categories

Let \( M \) be an abelian group, and let \( \text{End}(M) \) denote the set of group homomorphisms from \( M \) to itself. Then \( \text{End}(M) \) is endowed with the structure of an associative ring, where addition is given pointwise and multiplication is given by composition of homomorphisms. Moreover, we can characterize \( \text{End}(M) \) by the following universal property: for any associative ring \( R \), giving a ring homomorphism \( \phi: R \to \text{End}(M) \) is equivalent to endowing \( M \) with the structure of an \( R \)-module.
In this section, we will generalize the above ideas by replacing the ordinary category of abelian groups (with its tensor product) by an arbitrary monoidal ∞-category \( \mathcal{C} \). If \( M \in \mathcal{C} \) is an object, then an endomorphism object for \( M \) is an object \( E \in \mathcal{C} \) equipped with a map \( a : E \otimes M \to M \) which enjoys the following universal property: for every other object \( C \in \mathcal{C} \), composition with \( a \) induces a homotopy equivalence \( \text{Map}_C(C, E) \to \text{Map}_C(C \otimes M, M) \). We will show that if an endomorphism object \( E \) exists, then \( E \) has the structure of an associative algebra object of \( \mathcal{C} \). Moreover, it is universal among associative algebras which act on \( M \) in the following sense: for every associative algebra object \( A \in \text{Alg}(\mathcal{C}) \), there is a homotopy equivalence

\[
\text{Map}_{\text{Alg}(\mathcal{C})}(A, E) \simeq \{ A \} \times \text{Mod}(\mathcal{C}) \times \{ M \}.
\]

We will prove these assertions in §4.7.2 by identifying \( E \) with the final object of a monoidal ∞-category \( \mathcal{C}[M] \) determined by \( \mathcal{C} \) and \( M \).

With an eye toward later applications, we will treat a slightly more general problem. Suppose that \( \mathcal{C} \) is a monoidal ∞-category, that \( \mathcal{M} \) is an ∞-category which is left-tensored over \( \mathcal{C} \), and that \( M \) is an object of \( \mathcal{M} \). Let us say that an object \( C \in \mathcal{C} \) acts on \( \mathcal{M} \) if we are given a map \( C \otimes M \to M \). We would like to extract an object \( \text{End}(M) \in \mathcal{C} \) which is universal among objects which act on \( M \), and show that \( \text{End}(M) \) is an algebra object of \( \mathcal{C} \) (and further, that \( M \) can be promoted to an object of \( \text{LMod}_{\text{End}(M)}(\mathcal{M}) \)).

Our first goal is to give a careful formulation of the universal property desired of \( \text{End}(M) \). We would like to have, for every algebra object \( A \in \text{Alg}(\mathcal{C}) \), a homotopy equivalence of \( \text{Map}_{\text{Alg}(\mathcal{C})}(A, \text{End}(M)) \) with a suitable classifying space for actions of \( A \) on \( M \). The natural candidate for this latter space is the fiber product \( \{ A \} \times_{\text{Alg}(\mathcal{C})} \text{Mod}(\mathcal{M}) \times_{\mathcal{M}} \{ M \} \), which can be viewed as a fiber of the projection map \( \theta : \text{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{ M \} \to \text{Alg}(\mathcal{C}) \). We will see below that \( \theta \) is a right fibration (Corollary 4.7.2.42). Our problem is therefore to find an object \( \text{End}(M) \in \text{Alg}(\mathcal{C}) \) which represents the right fibration \( \theta \), in the sense that we have a natural equivalence \( \text{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{ M \} \simeq \text{Alg}(\mathcal{C})/\text{End}(M) \) of right fibrations over \( \text{Alg}(\mathcal{C}) \) (see §T.4.4.4).

The next step is to realize the ∞-category \( \text{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{ M \} \) as (equivalent to) the ∞-category of algebra objects in a suitable monoidal ∞-category \( \mathcal{C}[M] \). Roughly speaking, we will think of objects of \( \mathcal{C}[M] \) as pairs \( (C, \eta) \), where \( C \in \mathcal{C} \) and \( \eta : C \otimes M \to M \) is a morphism in \( \mathcal{M} \). The monoidal structure on \( \mathcal{C}[M] \) may be described informally by the formula \( (C, \eta) \otimes (C', \eta') = (C \otimes C', \eta''), \) where \( \eta'' \) denotes the composition

\[
C \otimes C' \otimes M \overset{id \otimes \eta'}{\longrightarrow} C \otimes M \overset{\eta''}{\longrightarrow} M.
\]

The desired object \( \text{End}(M) \) can be viewed as a final object of \( \mathcal{C}[M] \). Provided that this final object exists, it automatically has the structure of an algebra object of \( \mathcal{C}[M] \) (Corollary 3.2.2.4). The image of \( \text{End}(M) \) under the (monoidal) forgetful functor \( \mathcal{C}[M] \to \mathcal{C} \) will therefore inherit the structure of an algebra object of \( \mathcal{C} \).

We are now ready to begin with a detailed definition of the monoidal ∞-category \( \mathcal{C}[M] \). For technical reasons, it will be convenient to work in the setting of \( \Delta \)-monoidal ∞-categories (see §4.7.1).

**Definition 4.7.2.1.** Let \( p : \mathcal{M}^\otimes \to \Delta^1 \times \text{N}(\Delta)^{op} \) be a map which exhibits \( \mathcal{M} = \mathcal{M}^\otimes_{0,[0]} \) as weakly enriched over the \( \Delta \)-planar ∞-operad \( \mathcal{C}^\otimes = \mathcal{M}^\otimes \times_{\Delta^1} \{ 1 \} \). An enriched morphism of \( \mathcal{M} \) is a diagram

\[
M \overset{\beta}{\longrightarrow} X \overset{\alpha}{\twoheadrightarrow} N
\]

in \( \mathcal{M}^\otimes \) satisfying the following conditions:

- The image \( p(\alpha) \) is the morphism \( (0, [1]) \to (0, [0]) \) in \( \Delta^1 \times \text{N}(\Delta)^{op} \) determined by the embedding \( [0] \simeq \{ 0 \} \hookrightarrow [1] \) in \( \Delta \).

- The map \( \beta \) is inert, and \( p(\beta) \) is the morphism \( (0, [1]) \to (0, [0]) \) in \( \Delta^1 \times \text{N}(\Delta)^{op} \) determined by the embedding \( [0] \simeq \{ 1 \} \hookrightarrow [1] \) in \( \Delta \).

We let \( \text{Str} \mathcal{M}^\otimes_{[1]} \) denote the full subcategory of \( \text{Fun}_{\Delta^1 \times \text{N}(\Delta)^{op}}(\Lambda^2_0, \mathcal{M}^\otimes) \) spanned by the enriched morphisms of \( \mathcal{M} \).
There is an evident pair of evaluation functors \( \text{Str} \mathcal{M}_{[1]} \to \mathcal{M} \). Given an object \( M \in \mathcal{M} \), we let \( \mathcal{C}[M] \) denote the fiber product \( \{M\} \times_{\mathcal{M}} \text{Str} \mathcal{M}_{[1]} \times \mathcal{M} \{M\} \). We will refer to \( \mathcal{C}[M] \) as the endomorphism \( \infty \)-category of \( M \).

**Remark 4.7.2.2.** The notation of Definition 1.3.2.11 is abusive: the \( \infty \)-categories \( \text{Str} \mathcal{M}_{[1]} \) and \( \mathcal{C}[M] \) depend not only on \( \mathcal{M} \) and \( M \), but also on the weak enrichment \( p : \mathcal{M} \to \Delta^1 \times N(\Delta)^{\text{op}} \).

**Remark 4.7.2.3.** Let \( p : \mathcal{M}^{\otimes} \to \Delta^1 \times N(\Delta)^{\text{op}} \) be a map which exhibits \( \mathcal{M} = \mathcal{M}_{0,[0]} \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}^{\otimes} = \mathcal{M}^{\otimes} \times_{\Delta^1} \{1\} \), and let \( M \in \mathcal{M} \) be an object. By definition, a object of \( \mathcal{C}[M] \) consists of the following data:

- An inert morphism \( \beta : X \to M \) covering the map \( (0,[1]) \to (0,[0]) \) given by \( \{0\} \to \{1\} \) in \( \Delta \). We can think of \( \beta \) as giving an equivalence \( M \to \Delta \).
- An object \( X \in \mathcal{C} \), which we can think of as consisting of a pair of objects \( C \in \mathcal{C} \), \( M' \in \mathcal{M} \).
- An ordered set \( [\infty] \) of objects \( \{C_0, C_1, \ldots, C_n\} \in \mathcal{C} \), which admit a linearly ordered set \( [n] \), and \( M' \in \mathcal{M} \).
- A morphism \( \alpha : X \to M \) covering the map \( (0,[1]) \to (0,[0]) \) given by \( \{0\} \to \{1\} \to [1] \) in \( \Delta \). If \( p \) is a coCartesian fibration (so that \( \mathcal{M} \) is left-tensored over the \( \Delta \)-monoidal \( \infty \)-category \( \mathcal{C}^{\otimes} \)), then we can think of \( \alpha \) as given by a map \( C \otimes M' \to M \).

It follows that if \( p \) is a coCartesian fibration, then we can think of objects of \( \mathcal{C}[M] \) as pairs \((C, \eta)\), where \( C \in \mathcal{C} \) and \( \eta : C \otimes M \to M \) is a morphism in \( \mathcal{M} \).

Our next goal is to show that in the situation of Definition 4.7.2.1, the \( \infty \)-category \( \mathcal{C}[M] \) is the underlying \( \infty \)-category of \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}[M]^{\otimes} \). We can think of the fiber \( \mathcal{C}[M]^{\otimes} \) as a sequence of objects \( C_0, C_1, \ldots, C_n \in \mathcal{C} \), equipped with maps \( \eta_i : C_i \otimes M \to M \) (at least in the case where \( p \) is a coCartesian fibration). We begin by describing this \( \infty \)-category in a way which is more evidently functorial in the linearly ordered set \( [n] \). Before proceeding, we need a simple observation:

**Remark 4.7.2.4.** Let \( p : \mathcal{M}^{\otimes} \to \Delta^1 \times N(\Delta)^{\text{op}} \) be a map which exhibits \( \mathcal{M} = \mathcal{M}_{0,[0]} \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}^{\otimes} = \mathcal{M}^{\otimes} \times_{\Delta^1} \{1\} \). Then the inclusion \( \mathcal{C}^{\otimes} \hookrightarrow \mathcal{M}^{\otimes} \) admits a left adjoint \( L \). For every object \( M \in \mathcal{C}^{\otimes} \), the localization map \( \mathcal{M} \to LM \) is an inert morphism in \( \mathcal{M}^{\otimes} \) covering the map \( (0,[n]) \to (1,[n]) \) in \( \Delta^1 \times N(\Delta)^{\text{op}} \).

**Notation 4.7.2.5.** Let \( n \geq 0 \) be an integer. We let \( \text{Po}_{[n]} \) denote the set \( \{(i,j) \in [n] \times [n] : i \leq j\} \). We will regard \( \text{Po}_{[n]} \) as partially ordered, where \( (i,j) \leq (i',j') \) if \( i' \leq i \leq j \). In other words, we have \( (i,j) \leq (i',j') \) if \( \{i,i+1, \ldots, j\} \subseteq \{i',i'+1, \ldots, j'\} \).

We define a functor \( \Phi_{[n]} : \text{Po}_{[n]} \to \Delta \) by the formula \( \Phi_{[n]}(i,j) = [j-i] \simeq \{i,i+1, \ldots, j\} \).

**Definition 4.7.2.6.** Let \( p : \mathcal{M}^{\otimes} \to \Delta^1 \times N(\Delta)^{\text{op}} \) be a map which exhibits \( \mathcal{M} = \mathcal{M}_{0,[0]} \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}^{\otimes} = \mathcal{M}^{\otimes} \times_{\Delta^1} \{1\} \). An \( \text{enriched} \) \( n \)-\( \text{string} \) in \( \mathcal{M} \) is a map \( \sigma : \text{N(Po}_{[n]}))^{\otimes} \to \mathcal{M}^{\otimes} \) with the following properties:

1. The composition \( p \circ \sigma \) is given by the composition

\[
\text{N(Po}_{[n]}))^{\otimes} \xrightarrow{\Phi_{[n]}} \text{N(\Delta)^{op}} \simeq \{0\} \times \text{N(\Delta)^{op}} \to \Delta^1 \times \text{N(\Delta)^{op}}
\]

where \( \Phi_{[n]} \) is defined as in Notation 4.7.2.5 and \( \text{LCut} \) as in Construction 4.2.2.6.

2. For \( i \leq i' \leq j \), the map \( \sigma(i',j) \to \sigma(i,j) \) is an inert morphism in \( \mathcal{M}^{\otimes} \).

3. Let \( L : \mathcal{M}^{\otimes} \to \mathcal{C}^{\otimes} \) be a left adjoint to the inclusion (see Remark 4.7.2.4). For \( i \leq i' \leq j' \leq j \), the map \( L\sigma(i',j') \to L\sigma(i,j) \) is an inert morphism in \( \mathcal{C}^{\otimes} \).
We let \( \text{Str}\ M_{[n]}^{\text{en}} \) denote the full subcategory of \( \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(N(P_{[n]}^{op}), M^\otimes) \) spanned by the enriched \( n \)-strings in \( M \). We will refer to \( \text{Str}\ M_{[n]}^{\text{en}} \) as the \( \infty \)-category of enriched \( n \)-strings in \( M \).

**Warning 4.7.2.7.** As with Definition 1.3.2.11, our notation is abusive: the \( \infty \)-category \( \text{Str}\ M_{[n]}^{\text{en}} \) depends not only on the \( \infty \)-category \( M \), but also on the weak enrichment \( M^\otimes \to \Delta^1 \times N(\Delta)^{op} \).

**Example 4.7.2.8.** When \( n = 1 \), condition (3) of Definition 4.7.2.6 is automatic. Consequently, an enriched \( n \)-string in \( M \) is just an enriched morphism in \( M \), in the sense of Definition 1.3.2.11. In particular, the notations of Definitions 1.3.2.11 and 4.7.2.6 are compatible with one another.

**Remark 4.7.2.9.** In the situation of Definition 4.7.2.6, let us say that an \( n \)-string \( \sigma \in M_{[n]}^{\text{en}} \) determined an \( n \)-string \( \{M_i\}_{0 \leq i \leq n} \) by the formula \( M_i = \sigma(i,i) \). This construction determines a forgetful functor \( \text{Str}\ M_{[n]}^{\text{en}} \to M^{[n]} \).

**Example 4.7.2.10.** If \( n = 0 \) in Definition 4.7.2.6, then \( P_{[n]} = \{0,0\} \) and the forgetful functor \( \text{Str}\ M_{[n]}^{\text{en}} \to M^{[0]} \approx M \) is an isomorphism. In other words, an enriched 0-string in \( M \) is just an object of \( M \).

**Remark 4.7.2.11.** Let \( f : [m] \to [n] \) be a morphism in \( \Delta \). Then \( f \) induces a map of partially ordered sets \( P_{\Delta} : P_{[m]} \to P_{[n]} \), given by \((i,j) \mapsto (f(i),f(j))\). Suppose further that \( f \) is an inert morphism in \( \Delta \): that is, \( f \) induces a bijection from \( [m] \) to \( \{i,i+1, \ldots, j\} \subseteq [n] \) for some \( 0 \leq i \leq j \leq n \). Then the diagram

\[
\begin{array}{ccc}
P_{[m]} & \xrightarrow{\Phi_{[m]}} & P_{[n]} \\
\downarrow{P_{\Delta}} & & \downarrow{P_{\Delta}} \\
\Delta & & \Delta
\end{array}
\]

is commutative. It follows that for any \( p : M^\otimes \to \Delta^1 \times N(\Delta)^{op} \) as in Definition 4.7.2.6, composition with \( P_{\Delta} \) induces a forgetful functor \( \text{Str}\ M_{[n]}^{\text{en}} \to \text{Str}\ M_{[m]}^{\text{en}} \).

**Notation 4.7.2.12.** Let \( p : M^\otimes \to \Delta^1 \times N(\Delta)^{op} \) be as in Definition 4.7.2.6, and let \( S \) be a convex subset of \([n] \) for some \( n \geq 0 \). Then \( S \) is the image of a unique injective map \( f : [m] \to [n] \) in \( \Delta \). We let \( \text{Str}\ M_{[m]}^S \) denote the \( \infty \)-category \( \text{Str}\ M_{[m]}^{\text{en}} \), so that Remark 4.7.2.11 produces a forgetful functor \( \text{Str}\ M_{[n]}^{\text{en}} \to \text{Str}\ M_{[m]}^{S} \).

The following result expresses the idea that an enriched \( n \)-string can be obtained by “composing” a chain of enriched morphisms (of length \( n \)):

**Proposition 4.7.2.13** (Segal Condition). Let \( p : M^\otimes \to \Delta^1 \times N(\Delta)^{op} \) be a map which exhibits \( M = M_{0,[n]}^\otimes \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}^\otimes = M^\otimes \times_{\Delta^1} \{1\} \). For each \( n \geq 0 \), the \( \infty \)-category \( \text{Str}\ M_{[n]}^{\text{en}} \) is a homotopy limit of the diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\text{Str}\ M_{[0]}^{\text{en}}_{\{0,1\}} & \cdots & \text{Str}\ M_{[n]}^{\text{en}}_{\{m-1,m\}} \\
\downarrow & & \downarrow \\
\text{Str}\ M_{[1]}^{\text{en}}_{\{1\}} & \cdots & \text{Str}\ M_{[n-1]}^{\text{en}}_{\{n-1\}} \\
\downarrow & & \downarrow \\
\text{Str}\ M_{[n]}^{\text{en}}_{\{n\}} & \cdots & \text{Str}\ M_{[n]}^{\text{en}}_{\{n\}}
\end{array}
\]

**Proof.** Let \( P_{[n]}^0 \) denote the subset of \( P_{[n]} \) consisting of those pairs \((i,j)\) where \( i \leq j \leq i+1 \), and let \( \mathcal{X} \) be the full subcategory of \( \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(N(P_{[n]}^{op})^{op}, M^\otimes) \) spanned by those functors whose restriction to \( N(P_{[n]}^{op})^{op} \) belongs to \( \text{Str}\ M_{[n]}^{\text{en}} \), for every map \([1] \to \{i,i+1\} \in [n] \). Then \( \mathcal{X} \) is a model for the homotopy limit in question; it will therefore suffice to show that the forgetful functor \( \theta : \text{Str}\ M_{[n]}^{\text{en}} \to \mathcal{X} \) is an equivalence of \( \infty \)-categories.

Let \( \text{Str}\ M_{[n]}^{\text{en}}_+ \) be the full subcategory of \( \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(P_{[n]}^{op})^{op}, M^\otimes) \) spanned by those functors \( F^+ \) satisfying the following pair of conditions:
(i) The restriction $F = F^+|\{0\} \times N(\text{Po}_{[n]}^{op})$ belongs to $\text{Str} M_{[n]}^{en}$.

(ii) For every object $(i, j) \in \text{Po}_{[n]}$, the map $F^+(0, i, j) \to F^+(1, i, j)$ is $p$-coCartesian. In other words, $F^+$ is a $p$-left Kan extension of $F$.

We define the full subcategory $X^+ \subseteq \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\text{Po}_{[n]}^{op}), M^\otimes)$ similarly. We have a commutative diagram of restriction maps

$$
\begin{array}{ccc}
\text{Str} M_{[n]}^{en,+} & \overset{\theta^+}{\longrightarrow} & X^+ \\
\downarrow & & \downarrow \\
\text{Str} M_{[n]}^{en} & \longrightarrow & X.
\end{array}
$$

Proposition T.4.3.2.15 implies that the vertical maps in this diagram are trivial Kan fibrations. It will therefore suffice to show that $\theta^+$ is a trivial Kan fibration. According to Proposition T.4.3.2.15, this is a consequence of the following pair of assertions:

(a) For every functor $F_0^+ \in X^+$, there exists a functor $F^+ \in \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\text{Po}_{[n]}^{op}), M^\otimes)$ such that $F^+$ is a $p$-right Kan extension of $F_0^+$.

(b) An arbitrary functor $F^+ \in \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\text{Po}_{[n]}^{op}), M^\otimes)$ belongs to $\text{Str} M_{[n]}^{en,+}$ if and only if $F_0^+ = F^+|\{0\} \times N(\text{Po}_{[n]}^{op})$ belongs to $X^+$, and $F^+$ is a $p$-right Kan extension of $F_0^+$.

We begin by proving (a). Fix an object $(a, i, j) \in \Delta^1 \times N(\text{Po}_{[n]}^{op})$, and let

$$
\mathcal{J} = (\Delta^1 \times N(\text{Po}_{[n]}^{op}) \times_{\Delta^1 \times N(\text{Po}_{[n]}^{op})} (\Delta^1 \times N(\Delta)^{op})_{(a, i, j)}/.
$$

According to Lemma T.4.3.2.13, it will suffice to show that $f = F_0^+|\mathcal{J}$ can be extended to a $p$-limit diagram $\mathcal{T} : \mathcal{J} \to M^\otimes$ lifting the evident map $\mathcal{J}^\otimes \to \Delta^1 \times N(\text{Po}_{[n]}^{op}) \to \Delta^1 \times N(\Delta)^{op}$.

We first treat the case where $a = 1$. Let $S$ be the full subcategory of $\mathcal{J}$ spanned by those triples of the form $(1, i', i' + 1)$ where $i \leq i' < j$. The inclusion $S \to \mathcal{J}$ is right cofinal. It therefore suffices to show that the collection of objects $\{f(1, i', i' + 1)\}_{i \leq i' < j}$ admit a $p$-product in $M^\otimes$, which follows from our assumption that $M^\otimes \times \Delta^1(1)$ is a $\Delta$-planar operad.

Assume now that $a = 0$. For $i \leq k \leq j$, let $\mathcal{J}(k)$ denote the full subcategory of $\mathcal{J}$ spanned by those triples $(b, i', j')$ where such that either $b = 0$ or $k \leq i' \leq j' \leq j$. We will prove that $f|\mathcal{J}(k)$ can be extended to a $p$-limit diagram $\mathcal{T}_k : \mathcal{J}(k)^\otimes \to M^\otimes$ (compatible with the map $\mathcal{J}^\otimes \to \Delta^1 \times N(\Delta)^{op}$) using descending induction on $k$. When $k = j$, let $S$ denote the discrete simplicial set with vertices $\{(0, j, j)\}$, and note that the inclusion $S \to \mathcal{J}$ is right cofinal; it will therefore suffice to show that there exists a $p$-product for the collection of objects $\{f(0, j, j)\}$, which follows from the assumption that the map $M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ is fibrous (see Proposition 4.7.1.13). Let us therefore assume that $k < j$ and that the extension $\mathcal{T}_{k+1}$ has been constructed. Let $\mathcal{J}(k)'$ denote the full subcategory of $\mathcal{J}(k)$ obtained by removing the object $(0, k, k)$. Since $F \in X^+$, the functor $f|\mathcal{J}(k)'$ is a $p$-right Kan extension of $f|\mathcal{J}(k+1)$. It follows from Lemma T.4.3.2.7 that $\mathcal{T}_{k+1}$ extends (in an essentially unique fashion) to a $p$-limit diagram $\mathcal{T}_k : \mathcal{J}(k)^\otimes \to M^\otimes$. The inclusion $\mathcal{J}(k)' \to \mathcal{J}(k)$ is right cofinal, so that we can further extend $\mathcal{T}_k$ (again in an essentially unique way) to a $p$-limit diagram $\mathcal{T}_k : \mathcal{J}^\otimes \to M^\otimes$. This completes the proof of (a). Moreover, the proof yields the following version of (b):

(b') Let $F^+ \in \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\text{Po}_{[n]}^{op}), M^\otimes)$ be such that $F_0^+ = F^+|\{0\} \times N(\text{Po}_{[n]}^{op})$ belongs to $X^+$. Then $F^+$ is a $p$-right Kan extension of $F_0^+$ if and only if, for each $0 \leq i \leq j \leq n$, the maps

$$
F^+(0, i, j) \to F^+(0, i, j), \quad F(0, i, j) \to F(1, i', i' + 1), \quad F(1, i, j) \to F(1, i', i' + 1)
$$

are inert, where $i \leq i' < j$. 

We now prove (b). Assume first that \( F^+ \in \text{Str}M[n]^{\text{en}}+ \). It is clear that \( F^+_0 = F^+|((\Delta^1 \times N(Po_{[n]}^0))^\text{op}) \) belongs to \( X' \); we wish to prove that \( F^+ \) is a p-right Kan extension of \( F^+_0 \). We will show that \( F^+ \) satisfies the criteria of \((b')\). Fix \( 0 \leq i \leq j \leq n \). Since \( F = F^+|((\{0\} \times N(Po_{[n]}^0))^\text{op}) \) belongs to \( \text{Str}M[n] \), the map \( F^+(0,i,j) \to F^+(0,j,j) \) is inert. For \( i \leq i' < j \), consider the composition
\[
F^+(0,i,j) \xrightarrow{\alpha} F^+(1,i,j) \xrightarrow{\beta} F^+(1,i',i'+1).
\]
We wish to show that \( \beta \) and \( \beta \circ \alpha \) are inert. Since \( \alpha \) is inert by \((ii)\), it will suffice to show that \( \beta \) is inert. Let \( L : M^{\text{op}} \to E^{\text{op}} \) be a left adjoint to the inclusion. Condition \((ii)\) implies that \( \beta = L(\beta') \), where \( \beta' \) is the map \( F^+(1,i,i') \to F^+(0,i',i'+1) \). The condition that \( F \in \text{Str}M[n] \) guarantees that \( L(\beta') \) is inert as desired.

We now prove the converse direction of \((b)\). Let \( F^+ \in \text{Fun}_{\Delta^1 \times N(\Delta)^{\text{op}}}((\Delta^1 \times N(Po_{[n]}^0))^\text{op}, E^{\text{op}}) \). Assume that \( F^+_0 = F^+|((\Delta^1 \times N(Po_{[n]}^0))^\text{op}) \) belongs to \( X' \) and that \( F^+ \) is a p-right Kan extension of \( F^+_0 \); we wish to prove that \( F^+ \) satisfies conditions \((i)\) and \((ii)\). We begin by verifying \((ii)\). Choose \( 0 \leq i \leq j \leq n \); we wish to show that the map \( \alpha : F^+(0,i,j) \to F^+(1,i,j) \) is inert. Condition \((b)\) implies that for \( i \leq k < j \), the map \( \beta_j : F^+(1,i,j) \to F^+(1,k,k+1) \) is inert; it will therefore suffice to show that each composition \( \beta_j \circ \alpha \) is inert, which follows from \((b')\).

We now complete the proof by showing that \( F = F^+|((\{0\} \times N(Po_{[n]}^0))^\text{op}) \) belongs to \( \text{Str}M[n]^{\text{en}} \). Fix \( 0 \leq i \leq i' \leq j \); we claim that the map \( \alpha : F^+(0,i,j) \to F^+(0,i',j) \) is an inert morphism in \( M^{\text{op}} \). Condition \((b')\) guarantees that we have inert maps \( \beta : F^+(0,i',j) \to F^+(0,j,j) \) and \( \gamma_k : F^+(0,i',j) \to F^+(0,k,\ldots,k+1) \) for \( k \leq k < j \). It will therefore suffice to show that the compositions \( \gamma_k \circ \alpha \) and \( \beta \circ \alpha \) are inert, which also follows from \((b')\). To complete the proof that \( F \) is an enriched \( n \)-string, it suffices to show that \( LF \) carries each morphism in \( Po_{[n]} \) to an inert morphism in \( E^{\text{op}} \). Fix \( 0 \leq i \leq i' \leq j' \leq j \); we wish to show that the map \( \delta : LF(i,j) \to LF(i',j') \) is inert. Using \((ii)\), we can identify \( \delta \) with the map \( F^+(1,i,j) \to F^+(1,i',j') \). Condition \((b')\) implies that the maps \( F^+(1,i',j') \to F^+(1,k,k+1) \) are inert for \( i' \leq k < j' \). It will therefore suffice to show that each of the composite maps \( F^+(1,i,j) \to F^+(1,k,k+1) \) is inert, which also follows from \((b')\).

We now study the relationship between the \( \infty \)-categories \( \text{Str}M[n]^{\text{en}} \) as \( [n] \) varies. As we will see, they can be identified with the fibers of a certain categorical fibration \( \text{Str}M[n]^{\text{en}} \to N(\Delta)^{\text{op}} \).

**Notation 4.7.2.14.** We define a category \( Po \) as follows:

- The objects of \( Po \) are triples \([n], i, j\) where \( n \in \Delta \) and \( 0 \leq i \leq j \leq n \).
- Given a pair of objects \([n], i, j\), \([n'], i', j'\) \( Po \), a morphism from \([n], i, j\) to \([n'], i', j'\) is a map of linearly ordered sets \( \alpha : [n] \to [n'] \) such that \( i' \leq \alpha(i) \leq \alpha(j) \leq j' \) (equivalently, \( \alpha \{ i, i+1, \ldots, j \} \subseteq \{ i', i'+1, \ldots, j' \} \)).
- Composition of morphisms in \( Po \) is defined in the obvious way.

We let \( Po' \) denote the full subcategory of \( Po \) spanned by those objects of the form \([n], i, i\).

**Remark 4.7.2.15.** There is an evident forgetful functor \( \theta : Po \to \Delta \). The fiber of \( \theta \) over an object \([n] \) is the category associated to the partially ordered set \( Po_{[n]} \) of Notation 4.7.2.5.

The functor \( \theta \) exhibits \( Po \) as cofibered in categories of \( \Delta \); in other words, the induced map \( N(Po) \to N(\Delta) \) is a coCartesian fibration of simplicial sets. A morphism \( \alpha : ([n], i, j) \to ([n'], i', j') \) is \( \theta \)-coCartesian if and only if \( i' = \alpha(i) \) and \( j' = \alpha(j) \).

**Remark 4.7.2.16.** The functors \( \Phi_{[n]} : Po_{[n]} \to \Delta \) introduced in Notation 4.7.2.5 are given by the restriction of a single functor \( \Phi : Po \to \Delta \), which is given on objects by the formula \( \Phi([n], i, j) = [j-i] \simeq \{ i, i+1, \ldots, j \} \).

**Construction 4.7.2.17.** We regard the \( \infty \)-category \( N(Po)^{\text{op}} \) as equipped with forgetful functors \( N(Po)^{\text{op}} \to N(\Delta)^{\text{op}} \) (given by the forgetful functor \( ([n], i, j) \to [n] \)) and \( N(Po)^{\text{op}} \to \Delta^1 \times N(\Delta)^{\text{op}} \), given by the composition
\[
N(Po)^{\text{op}} \xrightarrow{\Phi} N(\Delta)^{\text{op}} \simeq \{0\} \times N(\Delta)^{\text{op}} \to \Delta^1 \times N(\Delta)^{\text{op}}.
\]
Let $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a map which exhibits $M = M^\otimes_{0,0}$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{C}^\otimes = M^\otimes \times \Delta \{1\}$. We define maps of simplicial sets $\text{Str} \overset{\text{en}}{\rightarrow} \text{Str} \to N(\Delta)^{op}$ so that the following universal properties are satisfied: for every map of simplicial sets $K \to N(\Delta)^{op}$, there are canonical bijections

$$\text{Fun}_{N(\Delta)^{op}}(K, \overset{\text{en}}{\text{Str}}) \simeq \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(K \times N(\Delta)^{op}, N(\text{Po})^{op}, M^\otimes)$$

$$\text{Fun}_{N(\Delta)^{op}}(K, \text{Str} M) \simeq \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(K \times N(\Delta)^{op}, N(\text{Po})^{op}, M^\otimes).$$

Unwinding the definitions, we see that the fiber of $\overset{\text{en}}{\text{Str}}$ over an object $[n] \in \Delta^\op$ can be identified with $\text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(N(\text{Po})_{[n]}^{op}, M^\otimes)$. We let $\text{Str}^{\text{en}}$ denote the full simplicial subset of $\overset{\text{en}}{\text{Str}}$ spanned by those vertices which are enriched $n$-strings in $M$ (see Definition 4.7.2.6).

**Remark 4.7.2.18.** Let $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be as in Construction 4.7.2.17. For each $n \geq 0$, there are canonical isomorphisms

$$\text{Str} M^{\text{en}} \times_{N(\Delta)^{op}} \{[n]\} \simeq \text{Str} M^{\text{en}} \quad \text{Str} M \times_{N(\Delta)^{op}} \{[n]\} \simeq M^[n].$$

**Remark 4.7.2.19.** The $\infty$-category $\text{Str} M$ depends only on the $\infty$-category $M$, and not on the weak enrichment $M^\otimes \to \Delta^1 \times N(\Delta)^{op}$.

Since the map $N(\text{Po})^{op} \to N(\Delta)^{op}$ is a right fibration of simplicial sets, Corollary T.3.2.2.12 immediately implies the following:

**Proposition 4.7.2.20.** Let $M$ be an $\infty$-category. Then the map $q_0 : \text{Str} M \to N(\Delta)^{op}$ is a coCartesian fibration. Moreover, a morphism $\alpha$ in $\text{Str} M$ is $q_0$-coCartesian if and only if, for every morphism $\beta$ in $N(\text{Po})^{op}$ lying under $q_0(\alpha)$, the image of $\beta$ (under $\alpha$) is an equivalence in $M$.

**Remark 4.7.2.21.** In the situation of Proposition 4.7.2.20, every map $f : [n] \to [m]$ of linearly ordered sets determines a functor $\text{Str} M_{[n]} \to \text{Str} M_{[m]}$, which can be identified with the functor $M^[m] \to M^[n]$ given by composition with $f$.

The analogous result for $\infty$-categories of enriched strings is a bit more difficult to state.

**Lemma 4.7.2.22.** Let $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a map which exhibits $M = M^\otimes_{0,0}$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{C}^\otimes = M^\otimes \times \Delta \{1\}$. Then:

1. The projection map $\overline{\eta} : \overset{\text{en}}{\text{Str}} M^{\text{en}} \to N(\Delta)^{op}$ is a categorical fibration.

2. For every object $X \in \overset{\text{en}}{\text{Str}} M^{\text{en}}$ and every inert morphism $\alpha : \overline{\eta}(X) \to [n]$ in $N(\Delta)^{op}$, there exists a $\overline{\eta}$-coCartesian morphism $\overline{\pi} : X \to Y$ in $\overset{\text{en}}{\text{Str}} M^{\text{en}}$ with $\overline{\eta}(\overline{\pi}) = \alpha$.

3. Let $\overline{\pi} : X \to Y$ be a morphism in $\overset{\text{en}}{\text{Str}} M^{\text{en}}$ such that $\alpha = \overline{\eta}(\overline{\pi})$ is an inert morphism $[m] \to [n]$ in $N(\Delta)^{op}$. Then $\overline{\pi}$ is $\overline{\eta}$-coCartesian if and only if, for every pair of integers $0 \leq i \leq j \leq n$, the induced map $X(\alpha(i), \alpha(j)) \to Y(i,j)$ is an equivalence in $M^\otimes$.

4. Let $\overline{\pi} : X \to Y$ satisfy the condition of (3). If $X \in \overset{\text{en}}{\text{Str}} M^{\text{en}}$, then $Y \in \overset{\text{en}}{\text{Str}} M^{\text{en}}$.

5. Assume that $p$ is a coCartesian fibration. Then the map $\overline{\eta}$ is a coCartesian fibration. Moreover, a morphism $\overline{\pi} : X \to Y$ in $N(\Delta)^{op}$ is $\overline{\eta}$-coCartesian if and only if, for every pair of integers $0 \leq i \leq j \leq n$, the induced map $X(\alpha(i), \alpha(j)) \to Y(i,j)$ is an inert morphism in $M^\otimes$, where $\alpha = \overline{\eta}(\overline{\pi})$.

6. Assume that $p$ is a coCartesian fibration, and let $\overline{\pi} : X \to Y$ be a morphism in $\overset{\text{en}}{\text{Str}} M^{\text{en}}$ satisfying the condition of (5). If $X \in \overset{\text{en}}{\text{Str}} M^{\text{en}}$, then $Y \in \overset{\text{en}}{\text{Str}} M^{\text{en}}$. 
4.7. MONADS AND THE BARR-BECK THEOREM

Proof. The map $\text{N}(\text{Po})^{\text{op}} \to \text{N}(\Delta)^{\text{op}}$ is a Cartesian fibration and therefore a flat categorical fibration (Example B.3.11). Assertion (1) now follows from Proposition B.4.5. Suppose that we are given an object $X \in \text{StrM}^n$ and an inert morphism $\alpha : [m] \to [n]$ in $\text{N}(\Delta)^{\text{op}}$. Let $Y_0 \in \text{StrM}^n$ be the composition of $X$ with the map $\text{N}(\text{Po})^{\text{op}} \to \text{N}(\text{Po})^{\text{op}}$ determined by $\alpha$. There is an evident map $\tau_0 : X \to Y_0$ covering $\alpha$, which is $q$-coCartesian by Lemma B.4.8. This proves (2). Note that the map $\tau_0$ satisfies the criterion of (3).

If $\tau : X \to Y'$ is any morphism covering $\alpha$, then the induced map $Y_0 \to Y$ is an equivalence if and only if $X(\alpha(i), \alpha(j)) \to Y(i, j)$ is an equivalence for all $0 \leq i \leq j \leq n$, which proves (3). For assertion (4), we may assume without loss of generality that $Y = Y_0$ in which case the result is obvious. Assertion (5) is a special case of Corollary T.3.2.2.12.

It remains to prove (6). Assume that $p$ is a coCartesian fibration and let $\tau : X \to Y$ be a $\tau$-coCartesian morphism which covers a map $\alpha : [m] \to [n]$ in $\text{N}(\Delta)^{\text{op}}$. Assume further that $X$ is an enriched $m$-string; we wish to show that $Y$ is an enriched $n$-string. Let $0 \leq i \leq i' \leq j \leq n$; we wish to show that $u : Y(i, j) \to Y(i', j)$ is an inert morphism in $\text{M}^\otimes$. Let $\mathcal{C}$ be the category of $\otimes$-operads. Suppose that we are given an object $\alpha : [m] \to [n]$ in $\text{N}(\Delta)^{\text{op}}$.

Since $v$ is $\tau$-coCartesian (by (5)), it will suffice to show that $u \circ v \simeq u' \circ u'$ is $\tau$-coCartesian. This follows from the fact that $u'$ and $v'$ are $\tau$-coCartesian (for $v'$ this follows from (5), for $u'$ it follows from our assumption that $X$ is an enriched $m$-string).

Let $L : \text{M}^\otimes \to \mathcal{C}^\otimes$ be a left adjoint to the inclusion. To complete the proof, we must show that for $0 \leq i \leq i' \leq j \leq n$, the map $f : LY(i, j) \to LY(i', j')$ is an inert morphism in $\mathcal{C}^\otimes$. The argument proceeds as above. Consider the diagram

$$
\begin{array}{ccc}
X(\alpha(i), \alpha(j)) & \xrightarrow{v} & Y(i, j) \\
\downarrow{u'} & & \downarrow{u} \\
X(\alpha(i'), \alpha(j)) & \xrightarrow{v'} & Y(i', j).
\end{array}
$$

Since $v$ is $\tau$-coCartesian morphisms in $\text{M}^\otimes$ to $\tau$-coCartesian morphisms in $\mathcal{C}^\otimes$, the morphisms $g$ and $g'$ are $\tau$-coCartesian. Consequently, to prove that $f$ is inert, it will suffice to show that $f \circ g \simeq g' \circ f'$ is $\tau$-coCartesian. We are therefore reduced to showing that $f'$ is $\tau$-coCartesian, which follows from our assumption that $X$ is an enriched $m$-string.

From Lemma 4.7.2.22 we immediately deduce the following:

**Proposition 4.7.2.23.** Let $p : \text{M}^\otimes \to \Delta^1 \times \text{N}(\Delta)^{\text{op}}$ be a map which exhibits $\text{M} = \text{M}^\otimes_{0, [0]}$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{C}^\otimes = \text{M}^\otimes \times_{\Delta^1} \{1\}$. Then:

1. The projection map $q : \text{StrM}^\otimes \to \text{N}(\Delta)^{\text{op}}$ is a categorical fibration.
2. For every object $X \in \text{StrM}^\otimes$ and every inert morphism $\alpha : \tau(X) \to [n]$ in $\text{N}(\Delta)^{\text{op}}$, there exists a $\otimes$-coCartesian morphism $\tau : X \to Y$ in $\text{StrM}^\otimes$ with $q(\tau) = \alpha$.
3. Let $\tau : X \to Y$ be a morphism in $\text{StrM}^\otimes$ such that $\alpha = q(\tau)$ is an inert morphism $[m] \to [n]$ in $\text{N}(\Delta)^{\text{op}}$. Then $\tau$ is $\otimes$-coCartesian if and only if, for every pair of integers $0 \leq i \leq j \leq n$, the induced map $X(\alpha(i), \alpha(j)) \to Y(i, j)$ is an equivalence in $\text{M}^\otimes$.
4. Assume that $p$ is a coCartesian fibration. Then the map $q$ is a coCartesian fibration. Moreover, a morphism $\tau : X \to Y$ in $\text{N}(\Delta)^{\text{op}}$ is $q$-coCartesian if and only if, for every pair of integers $0 \leq i \leq j \leq n$, the induced map $X(\alpha(i), \alpha(j)) \to Y(i, j)$ is an inert morphism in $\text{M}^\otimes$, where $\alpha = q(\tau)$. 

\[\square\]
Lemma 4.7.2.24. Let $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a map which exhibits $M = M_{0,[0]}^\otimes$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{C}^\otimes = \mathcal{M}^\otimes \times_\Delta \{1\}$, and let $q : \text{Str} \, M^\otimes \to N(\Delta)^{op}$ be the induced map. Let $n \geq 0$, let $Po_{[n]}^0 \subseteq Po_{[n]}$ be defined as in the proof of Proposition 4.7.2.13, and let $Po_{[n]}^1 = Po_{[n]} \cup \{(0,n)\} \subseteq Po_{[n]}$. Suppose we are given a diagram

$$
\begin{array}{ccc}
N(Po_{[n]}^1)^{op} & \xrightarrow{X} & \text{Str} \, M^\otimes \\
\downarrow & & \downarrow q \\
N(Po_{[n]}^0)^{op} & \xrightarrow{q} & N(\Delta)^{op}
\end{array}
$$

where $X$ carries each morphism in $Po_{[n]}^1$ to a $q$-coCartesian morphism in $\text{Str} \, M$. Then $X$ is a $q$-limit diagram.

Proof. Let $\mathcal{J}$ denote the fiber product $N(Po_{[n]}^0)^{op} \times_{N(\Delta)^{op}} N(Po_{[n]}^1)^{op}$, so that the objects of $\mathcal{J}$ can be identified with sequences $0 \leq i \leq i' \leq j' \leq j \leq n$ such that $(i,j) \in Po_{[n]}^0$, and let $\mathcal{J}_0$ be the full subcategory spanned by those objects where $(i,j) \in Po_{[n]}^0$. The diagram $X$ determines a functor $F : \mathcal{J} \to M^\otimes$. According to Proposition B.4.9, it will suffice to show that $F$ is a $p$-right Kan extension of $F_0 = F|\mathcal{J}_0$. Fix an object $\sigma \in \mathcal{J}$ which does not belong to $\mathcal{J}_0$, necessarily of the form $0 \leq i \leq i' \leq j' \leq j \leq n$, where $i = 0$ and $j = n$; we wish to prove that $F$ is a $p$-right Kan extension of $F_0$ at $\sigma$. Replacing $[n]$ by the interval $\{i', i' + 1, \ldots, j'\}$, we can reduce to the case where $i' = 0$ and $j' = n$. Then $\sigma$ is an initial object of $\mathcal{J}$, and we wish to prove that $F$ exhibits $F(\sigma)$ as a $p$-limit of the diagram $F_0$. Let $\mathcal{J}_1$ be the full subcategory of $\mathcal{J}_0$ spanned by those sequences $0 \leq i \leq i' \leq j' \leq j \leq 0$ where $i = i'$ and $j = j'$. The inclusion $\mathcal{J}_1 \subseteq \mathcal{J}_0$ admits a right adjoint, so that $\mathcal{J}_1 \to \mathcal{J}_0$ is right cofinal. It will therefore suffice to show that $F$ exhibits $F(\sigma)$ as a $p$-limit of the diagram $F_1 = F|\mathcal{J}_1$.

Let $L : M^\otimes \to \mathcal{C}^\otimes$ be a left adjoint to the inclusion and consider the natural transformation $F \to LF$, which we identify with a functor $F^+ : \Delta^1 \times \mathcal{J} \to M^\otimes$. It now suffices to show that $F^+$ exhibits $F^+(0,\sigma)$ as a $p$-limit of the diagram $F^+|\Delta^1 \times \mathcal{J}_1$. This follows from assertion (b) in the proof of Proposition 4.7.2.13.

Lemma 4.7.2.25. Let $\mathcal{M}$ be an $\infty$-category and let $q_0 : \text{Str} \, M \to N(\Delta)^{op}$ be the induced map. Let $n \geq 0$, $Po_{[n]}^0$, and $Po_{[n]}^1$ be as in the statement of Lemma 4.7.2.24, and suppose we are given a diagram

$$
\begin{array}{ccc}
N(Po_{[n]}^1)^{op} & \xrightarrow{X} & \text{Str} \, M \\
\downarrow & & \downarrow q_0 \\
N(Po_{[n]}^0)^{op} & \xrightarrow{q_0} & N(\Delta)^{op}
\end{array}
$$

where $X$ carries each morphism in $Po_{[n]}^1$ to a $q_0$-coCartesian morphism in $\text{Str} \, M$. Then $X$ is a $q_0$-limit diagram.

Proof. Let $\mathcal{J}$ denote the fiber product $N(Po')^{op} \times_{N(\Delta)^{op}} N(Po_{[n]}^1)^{op}$, so that the objects of $\mathcal{J}$ can be identified with sequences $0 \leq i \leq k \leq j \leq n$ such that $(i,j) \in Po_{[n]}^1$, and let $\mathcal{J}_0$ be the full subcategory spanned by those objects where $(i,j) \in Po_{[n]}^0$. The diagram $X$ determines a functor $F : \mathcal{J} \to M$. According to Proposition B.4.9, it will suffice to show that $F$ is a right Kan extension of $F_0 = F|\mathcal{J}_0$. Fix an object $\sigma \in \mathcal{J}$ given by $0 \leq i \leq k \leq j \leq n$ and let $\mathcal{J}' = \mathcal{J}_0 \times \mathcal{J}_0$. We wish to show that $F$ exhibits $F(\sigma)$ as a limit of the diagram $F|\mathcal{J}'$. Since $F$ carries every morphism in $\mathcal{J}$ to an equivalence in $\mathcal{M}$, it will suffice to show that $\mathcal{J}'$ is weakly contractible. This is clear, since $\mathcal{J}'$ has a final object.

Remark 4.7.2.26. In the situation of Lemma 4.7.2.25, we will say that a morphism $\alpha$ in $\text{Str} \, M$ is inert if $q_0(\alpha)$ is inert and $\alpha$ is $q_0$-Cartesian.
Lemma 4.7.2.27. Let $p : \mathcal{M}^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a map which exhibits $\mathcal{M} = \mathcal{M}^\otimes_{0,[0]}$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{E}^\otimes = \mathcal{M}^\otimes \times_{\Delta^1} \{1\}$. Consider the diagram

$$\begin{array}{ccc}
\text{Str} \mathcal{M}^{en} & \xrightarrow{f} & \text{Str} \mathcal{M} \\
\downarrow q & & \downarrow q_0 \\
N(\Delta)^{op} & & 
\end{array}$$

Then:

1. The map $f : \text{Str} \mathcal{M}^{en} \to \text{Str} \mathcal{M}$ is a categorical fibration.

2. Let $X \in \text{Str} \mathcal{M}^{en}$ and suppose we are given an inert morphism $\alpha : f(X) \to Y$ in $\text{Str} \mathcal{M}$. Then there exists an $f$-coCartesian morphism $\overline{\alpha} : X \to Y$ lifting $\alpha$.

3. Let $\alpha : f(X) \to Y$ be as in (2), and let $\alpha_0 = q_0(\alpha) : [m] \to [n]$ be the induced morphism in $N(\Delta)^{op}$. An arbitrary morphism $\overline{\alpha} : X \to Y$ lifting $\alpha$ is $f$-coCartesian if and only if $\overline{\alpha}$ induces an equivalence $X(\alpha_0(i),\alpha_0(j)) \to Y(i,j)$ for $0 \leq i \leq j \leq n$.

4. Assume that $p$ is a coCartesian fibration, let $X \in \text{Str} \mathcal{M}^{en}$, and suppose we are given a $q_0$-coCartesian morphism $\alpha : f(X) \to Y$ in $\text{Str} \mathcal{M}$. Then there exists an $f$-coCartesian morphism $\overline{\alpha} : X \to Y$ lifting $\alpha$.

5. Let $\alpha : f(X) \to Y$ be as in (4), and let $\alpha_0 = q_0(\alpha) : [m] \to [n]$ be the induced morphism in $N(\Delta)^{op}$. An arbitrary morphism $\overline{\alpha} : X \to Y$ lifting $\alpha$ is $f$-coCartesian if and only if $\overline{\alpha}$ induces a $p$-coCartesian map $X(\alpha_0(i),\alpha_0(j)) \to Y(i,j)$ for $0 \leq i \leq j \leq n$.

6. Let $n \geq 0$, $\mathcal{P}_{[n]}^0$, and $\mathcal{P}_{[n]}^1$ be as in the statement of Lemma 4.7.2.24, and suppose we are given a diagram

$$\begin{array}{ccc}
N(\mathcal{P}_{[n]}^1)^{op} & \xrightarrow{X} & \text{Str} \mathcal{M}^{en} \\
\downarrow q & & \downarrow q_0 \\
N(\mathcal{P}_{[n]}^0)^{op} & \to & N(\Delta)^{op}.
\end{array}$$

If $X$ carries every morphism in $N(\mathcal{P}_{[n]}^1)^{op}$ to a $q$-coCartesian morphism in $\text{Str} \mathcal{M}^{en}$, then $X$ is an $f$-limit diagram.

Proof. To prove (1), it suffices to show that the map $\overline{f} : \text{Str} \mathcal{M}^{en} \to \text{Str} \mathcal{M}$ is a categorical fibration: that is, that $\overline{f}$ has the right lifting property with respect to every cofibration of simplicial sets $i : A \to B$ which is also a categorical equivalence. This is equivalent to the requirement that, for every map $B \to N(\Delta)^{op}$, the morphism $p$ has the right lifting property with respect to the induced map

$$j : (A \times_{N(\Delta)^{op}} N(\mathcal{P})^{op}) \coprod_{A \times_{N(\Delta)^{op}} N(\mathcal{P})^{op}} (B \times_{N(\Delta)^{op}} N(\mathcal{P})^{op}) \to B \times_{N(\Delta)^{op}} N(\mathcal{P})^{op}.$$

Since $p$ is a categorical fibration and $j$ is a cofibration, it suffices to show that $j$ is a categorical equivalence. Because the Joyal model structure is left proper, we are reduced to showing that the inclusions

$$A \times_{N(\Delta)^{op}} N(\mathcal{P})^{op} \to B \times_{N(\Delta)^{op}} N(\mathcal{P})^{op}$$

$$A \times_{N(\Delta)^{op}} N(\mathcal{P})^{op} \to B \times_{N(\Delta)^{op}} N(\mathcal{P})^{op}$$

are categorical equivalences. This follows from Proposition T.3.3.1.3, since the forgetful functors

$$N(\mathcal{P})^{op} \to N(\Delta)^{op}$$

$$N(\mathcal{P})^{op} \to N(\Delta)^{op}$$
are Cartesian fibrations.

Assertions (2), (3), (4), and (5) follow by combining Propositions 4.7.2.20, 4.7.2.23, and T.2.4.1.3. Similarly, assertion (6) follows from Lemma 4.7.2.24 and Proposition T.2.4.1.3.

**Definition 4.7.2.28.** Let \( p : \mathcal{M}^\otimes \to \Delta^1 \times N(\Delta)^{\otimes} \) be a map which exhibits \( \mathcal{M} = \mathcal{M}_{\otimes, 0}^\otimes \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}^\otimes = \mathcal{M}^\otimes \times \Delta \cdot \{1\} \). For every object \( \mathcal{M} \in \mathcal{M} \), we let \( \mathcal{C}[\mathcal{M}]^\otimes \) denote the fiber product \( \mathcal{N}(\Delta)^{\otimes} \times_{\str \mathcal{M}} \str \mathcal{M}^{\otimes} \), where the map \( \mathcal{N}(\Delta)^{\otimes} \to \str \mathcal{M} \) corresponds to the constant functor \( \mathcal{N}(\mathcal{P}_0)^{\otimes} \to \mathcal{M} \) taking the value \( \mathcal{M} \in \mathcal{M} \).

**Remark 4.7.2.29.** In the situation of Definition 4.7.2.28, consider the projection map \( \theta : \mathcal{C}[\mathcal{M}]^\otimes \to \mathcal{N}(\Delta)^{\otimes} \). The inverse image \( \theta^{-1}\{[1]\} \) is isomorphic to the \( \infty \)-category \( \mathcal{C}[\mathcal{M}] \) of Definition 4.7.2.1.

**Proposition 4.7.2.30.** Let \( p : \mathcal{M}^\otimes \to \Delta^1 \times N(\Delta)^{\otimes} \) be a map which exhibits \( \mathcal{M} = \mathcal{M}_{\otimes, 0}^\otimes \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}^\otimes = \mathcal{M}^\otimes \times \Delta \cdot \{1\} \). For every object \( \mathcal{M} \in \mathcal{M} \), the projection map \( \theta : \mathcal{C}[\mathcal{M}]^\otimes \to \mathcal{N}(\Delta)^{\otimes} \) exhibits \( \mathcal{C}[\mathcal{M}]^\otimes \) as a \( \Delta \)-planar \( \infty \)-operad. If \( p \) is a coCartesian fibration, then \( \theta \) exhibits \( \mathcal{C}[\mathcal{M}]^\otimes \) as a \( \Delta \)-monoidal \( \infty \)-category.

**Proof.** We verify that the functor \( \theta \) satisfies the requirements of Definition 4.1.11. Conditions (1) and (2) follow immediately from Lemma 4.7.2.27 (which also implies that \( \theta \) is a coCartesian fibration if \( p \) is a coCartesian fibration), and condition (4) follows from Proposition 4.7.2.13. To verify condition (3), consider an object \( X \in \mathcal{C}[\mathcal{M}]^\otimes \) and a collection of \( \theta \)-coCartesian morphisms \( \alpha_i : X \to X_i \) covering the maps \( [n] \to [1] \) in \( \mathcal{N}(\Delta)^{\otimes} \) given by the inclusions \( [1] \simeq \{1 - 1, i\} \to [n] \) in \( \Delta \) for \( 1 \leq i \leq n \). We wish to prove that the maps \( \alpha_i \) exhibit \( X \) as a \( \theta \)-product of the objects \( X_i \). Assume for notational simplicity that \( n \neq 1 \) (otherwise the result is obvious). Let \( \mathcal{P}_0^{[n]} \) be as in the statement of Lemma 4.7.2.24 and let \( \mathcal{P}_0^{[n]} \subseteq \mathcal{P}_1^{[n]} \) be the subset consisting of pairs \( (i, j) \) where either \( (i, j) = (0, n) \) or \( j = i + 1 \). The morphisms \( \{\alpha_i\}_{1 \leq i \leq n} \) determine a diagram \( X_0 : \mathcal{N}(\mathcal{P}_1^{[n]})^{\otimes} \to \str \mathcal{M}^{\otimes} \) which fits into a commutative diagram

\[
\begin{array}{ccc}
N(\mathcal{P}_0^{[n]})^{\otimes} & \xrightarrow{X_0} & \str \mathcal{M}^{\otimes} \\
p | \downarrow & & \downarrow f \\
N(\mathcal{P}_1^{[n]})^{\otimes} & \xrightarrow{X} & \str \mathcal{M}.
\end{array}
\]

We wish to prove that \( X_0 \) determines a \( \theta \)-limit diagram in \( \mathcal{C}[\mathcal{M}]^\otimes \). Using Lemma T.4.3.2.13, we can choose an \( f \)-left Kan extension \( X \) of \( X_0 \) as indicated in the diagram. Lemma 4.7.2.27 implies that \( X \) is an \( f \)-limit diagram, so that \( X \) determines a \( \theta \)-limit diagram \( X' \) in \( \mathcal{C}[\mathcal{M}]^\otimes \). To complete the proof, it will suffice to show that \( X' \) is a \( \theta \)-limit diagram in \( \mathcal{C}[\mathcal{M}]^\otimes \). In view of Lemma T.4.3.2.7, it will suffice to show that \( X' \) is a \( \theta \)-right Kan extension of \( X' \). Unwinding the definitions, it will suffice to show that every object \( Y \in \mathcal{C}[\mathcal{M}]^\otimes \) is \( \theta \)-final. To this end, choose any object \( Z \in \mathcal{C}[\mathcal{M}]^\otimes \) and any morphism \( \alpha : [n] \to [0] \) in \( \mathcal{N}(\Delta)^{\otimes} \); we wish to show that mapping space

\[
\text{Map}_{\mathcal{C}[\mathcal{M}]^\otimes}(Z, *) = \text{Map}_{\mathcal{C}[\mathcal{M}]^\otimes}(Z, Y) \times_{\text{Hom}_{\Delta^{[0],[n]} \{\alpha\}}} \{\alpha\}
\]

is weakly contractible. Since \( \alpha \) is inert, we can choose a \( \theta \)-coCartesian morphism \( Z \to Z_0 \) in \( \mathcal{C}[\mathcal{M}]^\otimes \) lying over \( \alpha \). It will therefore suffice to show that the mapping space \( \text{Map}_{\mathcal{C}[\mathcal{M}]^\otimes}(Z_0, Y) \) is contractible. This is clear, since \( \mathcal{C}[\mathcal{M}]^\otimes \) is isomorphic to \( \Delta^0 \).

**Remark 4.7.2.31.** In the situation of Definition 4.7.2.1, the \( \infty \)-category \( \mathcal{C}[\mathcal{M}] \times_{\overline{\mathcal{C}}} \{1_e\} \) can be identified with the Kan complex \( \mathcal{M}^\otimes \times_{\mathcal{M}} \{M\} \simeq \text{Map}_{\mathcal{M}}(M, M) \). The monoidal structure on \( \mathcal{C}[\mathcal{M}] \) induces a coherently associative multiplication on \( \text{Map}_{\mathcal{M}}(M, M) \), which simply encodes the composition in the \( \infty \)-category \( \mathcal{M} \). In particular, if \( 1_e \) is an object of \( \mathcal{C}[\mathcal{M}] \times_{\overline{\mathcal{C}}} \{1_e\} \) which classifies an equivalence from \( M \) to itself, then \( 1_e \) is an invertible object of \( \mathcal{C}[\mathcal{M}] \) (see Remark 4.1.1.19).
4.7. MONADS AND THE BARR-BECK THEOREM

In what follows, it will be convenient to work with a slight variant of the ∞-category $\mathcal{C}[M]^\otimes$.

**Definition 4.7.2.32.** Let $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a map which exhibits $M = M^\otimes_{0,[0]}$ as weakly enriched over the $\Delta$-planar ∞-operad $\mathcal{C}^\otimes = M^\otimes \times_{\Delta^1} \{1\}$. We define maps of simplicial sets $\text{Str} M^m_{+} \to N(\Delta)^{op}$ so that the following universal property is satisfied: for every map of simplicial sets $K \to N(\Delta)^{op}$, there are canonical bijections

$$
\text{Fun}_{N(\Delta)^{op}}(K, \text{Str} M^m_{+}) \simeq \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times K \times N(\Delta)^{op}, N(\text{Po})^{op}, M^\otimes)
$$

Unwinding the definitions, we see that the fiber of $\text{Str} M^m_{+}$ over an object $[n] \in \Delta^{op}$ can be identified with $\text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\text{Po})_{[n]}^{op}, M^\otimes)$. We let $\text{Str} M^m_{+}$ denote the full simplicial subset of $\text{Str} M^m_{+}$ spanned by those vertices which correspond to functors $F : \Delta^1 \times N(\text{Po})_{[n]}^{op} \to M^\otimes$ such that $F_0 = F([0] \times N(\text{Po})_{[n]}^{op}$ is an enriched $n$-string and $F$ is a $p$-left Kan extension of $F_0$. The inclusion $[0] \times N(\text{Po})^{op} \to \Delta^1 \times N(\text{Po})^{op}$ induces a trivial Kan fibration $u : \text{Str} M^m_{+} \to \text{Str} M$. If $M \in \text{M}$ is an object, we let $\mathcal{C}^{\otimes +}[M]^\otimes$ denote the fiber product $\mathcal{C}[M]^\otimes \times_{\text{Str} M}$ $\text{Str} M^m_{+}$, so that $u$ induces a trivial Kan fibration $\mathcal{C}^{\otimes +}[M]^\otimes \to \mathcal{C}[M]^\otimes$.

**Remark 4.7.2.33.** Consider the functor $i : N(\Delta)^{op} \to \Delta^1 \times N(\text{Po})^{op}$, given by $[n] \mapsto (1, ([n], 0, n))$. In the situation of Definition 4.7.2.32, let $q^+$ denote the projection map $\mathcal{C}^{\otimes +}[M]^\otimes \to N(\Delta)^{op}$. It follows from Proposition 4.7.2.30 that $q^+$ exhibits $\mathcal{C}^{\otimes +}[M]^\otimes$ as a $\Delta$-planar ∞-operad. Composition with $i$ induces a categorical fibration $\theta : \mathcal{C}^{\otimes +}[M]^\otimes \to \mathcal{C}^{\otimes}$, and Lemma 4.7.2.27 implies that $\theta$ is a map of $\Delta$-planar ∞-operads (that is, $\theta$ carries inert morphisms in $\mathcal{C}^{\otimes +}[M]^\otimes$ to inert morphisms in $\mathcal{C}^{\otimes}$). If $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ is a coCartesian fibration, then $q^+$ is a coCartesian fibration and $\theta$ carries $q^+$-coCartesian morphisms to $p$-coCartesian morphisms (that is, $\theta$ is a map of $\Delta$-monoidal ∞-categories).

We now come to the main result of this section, which describes the ∞-category of algebra objects of $\mathcal{C}[M]^\otimes$.

**Theorem 4.7.2.34.** Let $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a map which exhibits $M = M^\otimes_{0,[0]}$ as weakly enriched over the $\Delta$-planar ∞-operad $\mathcal{C}^\otimes = M^\otimes \times_{\Delta^1} \{1\}$. Let $s : N(\Delta)^{op} \to N(\text{Po})^{op}$ be the functor given on objects by $[n] \mapsto ([n], 0, n)$. Then, for each object $M \in \text{M}$, composition with $s$ induces a categorical equivalence

$$
\theta : \Delta \text{Alg}(\mathcal{C}^{\otimes +}[M]) \to \Delta \text{LMod}(M) \times_{\text{M}} \{M\}.
$$

**Remark 4.7.2.35.** In the situation of Theorem 4.7.2.34, we obtain an equivalence of ∞-categories

$$
\Delta \text{Alg}(\mathcal{C}[M]) \to \Delta \text{LMod}(M) \times_{\text{M}} \{M\}
$$

(well-defined up to a contractible space of choices) by composing a section of the trivial Kan fibration $\Delta \text{Alg}(\mathcal{C}^{\otimes +}[M]) \to \Delta \text{Alg}(\mathcal{C}[M])$ with the categorical equivalence

$$
\theta : \Delta \text{Alg}(\mathcal{C}^{\otimes +}[M]) \to \Delta \text{LMod}(M) \times_{\text{M}} \{M\}.
$$

**Proof.** Let $X \subseteq \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\text{Po})^{op}, M^\otimes)$ be the full subcategory spanned by those functors $F$ satisfying the following conditions:

(a) If $0 \leq i \leq i' \leq j \leq n$, then the map $F([0, [n], i, j]) \to F([0, [n], i', j])$ is inert.

(b) If $0 \leq i \leq i' \leq j' \leq n$, then the map $F([1, [n], i, j]) \to F([1, [n], i', j'])$ is inert.

(c) For $0 \leq i \leq j \leq n$, the map $F([0, [n], i, j]) \to F([1, [n], i, j])$ is inert.

(d) If $\alpha : [m] \to [n]$ is an inert morphism in $\Delta$, then $F([0, [n], \alpha(i), \alpha(j)]) \to F([0, [m], i, j])$ is an equivalence in $M^\otimes$. 

Note that conditions (a) and (d) imply the following:

(a') For every inert morphism $\alpha : [m] \to [n]$ in $\Delta$ satisfying $\alpha(m) = n$, the induced map $F(0, [n], 0, n) \to F(0, [m], 0, m)$ is inert.

Similarly, (b) and (d) imply:

(b') For every inert morphism $\alpha : [m] \to [n]$ in $\Delta$, the induced map $F(1, [n], 0, n) \to F(1, [m], 0, m)$ is inert.

Finally, (c) and (d) imply:

(d') If $\alpha : [m] \to [n]$ is an inert morphism in $\Delta$, then $F(1, [n], \alpha(i), \alpha(j)) \to F(1, [m], i, j)$ is an equivalence in $M_{\otimes}$.

It follows that composition with $s$ induces a forgetful functor $\theta' : \mathcal{X} \to \Delta LMod(M)$. Let $\mathcal{X}_0 \subseteq \text{Fun}(N(\text{Po}^{\otimes}), M)$ be the full subcategory spanned by those functors which carry each morphism in $N(\text{Po}^{\otimes})$ to an equivalence. Let $M \in M_{\otimes}$ be the constant functor taking the value $M \in M$. Unwinding the definitions, we have a canonical isomorphism $\Delta \text{Alg}(\mathcal{C}^+[M]) = \mathcal{X} \times \mathcal{X}_0 \overrightarrow{M}$. In other words, we can identify $\theta'$ with the map between vertical fibers determined by the diagram

\[
\begin{array}{ccc}
\mathcal{X} & \xrightarrow{\phi} & \Delta LMod(M) \\
\downarrow & & \downarrow \\
\mathcal{X}_0 & \xrightarrow{\phi_0} & M.
\end{array}
\]

It will therefore suffice to show that the functors $\phi$ and $\phi_0$ are categorical equivalences. The map $\phi_0$ is an equivalence since $N(\text{Po}^{\otimes})$ is weakly contractible (it has a final object, given by $(0), 0, 0)$. It will therefore suffice to show that $\phi$ is a categorical equivalence. Let $\mathcal{X}'$ be the full subcategory of $\text{Fun}_{\Delta \times N(\Delta)^{op}}(\{0\} \times N(\text{Po}^{\otimes}), M_{\otimes})$ spanned by those functors $F$ which satisfy (a’), (b’), (d’), and the following weaker version of (c):

(c’) For $n \geq 0$, the map $F(0, [n], 0, n) \to F(1, [n], 0, n)$ is inert.

A functor $F \in \text{Fun}_{\Delta \times N(\Delta)^{op}}(\{0\} \times N(\text{Po}^{\otimes}), M_{\otimes})$ belongs to $\mathcal{X}'$ if and only if $F_0 = F(\Delta^1 \times N(\Delta)^{op})$ determines an object of $\Delta LMod(M)$ and $F$ is a p-right Kan extension of $F_0$. Then $\mathcal{X}'$ is a full subcategory of $\mathcal{X}$ and Proposition T.4.3.2.15 guarantees that the restriction map $\phi|\mathcal{X}'$ is a trivial Kan fibration. We will complete the proof by showing that $\mathcal{X} = \mathcal{X}'$. In other words, we will show that a functor $F \in \mathcal{X}'$ also satisfies conditions (a), (b), and (c). To prove (a), consider $0 \leq i \leq j \leq n$. Condition (d) guarantees that the induced map $F(0, [n], i, j) \to F(0, [n], i', j)$ is equivalent to the map $F([j-i], 0, j-i) \to F([j-i'], 0, j-i')$ and is therefore inert by (a’). To prove (b), we assume that $0 \leq i \leq j' \leq j \leq n$ and note that (d’) implies that $F(0, [n], i, j) \to F(0, [n], i', j')$ is equivalent to the map $LF([j-i], 0, j-i) \to LF([j'-i'], 0, j'-i')$ which is inert by (b’). It remains to verify (c). Fix $0 \leq i \leq j \leq n$: we wish to show that the map $u : F(0, [n], i, j) \to F(1, [n], i, j)$ is inert. Using (b), we are reduced to proving that the composite map $F(0, [n], i, j) \to F(1, [n], i, j) \simeq F(1, [j-i], 0, j-i)$ is inert. This map factors as a composition

\[
F(0, [n], i, j) \xrightarrow{u'} F(0, [j-i], 0, j-i) \xrightarrow{u''} F(1, [j-i], 0, j-i)
\]

where $u'$ is an equivalence by (a) and $u''$ is inert by virtue of (c’).

Our next goal is to analyze the relationship between the $\Delta$-planar $\infty$-operads $\mathcal{C}[M]_{\otimes}$ and $\mathcal{C}^{\otimes}$. In the situation of Definition 4.7.2.32, we let $\mathcal{C}^{\otimes}[M]$ denote the fiber product $\mathcal{C}^+[M]_{\otimes} \times_{N(\Delta)^{op}} \{1\}$. Our starting point is the following observation:

**Lemma 4.7.2.36.** Let $p : M^{\otimes} \to \Delta^1 \times N(\Delta)^{op}$ be a map which exhibits $M = M^{\otimes}_{0,0}$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{C}^{\otimes} = M^{\otimes} \times_{\Delta^1} \{1\}$. For every object $M \in M$, the categorical fibration $\theta : \mathcal{C}^+[M]^{\otimes} \to \mathcal{C}^{\otimes}$ of Remark 4.7.2.33 induces a right fibration of $\infty$-categories $\theta_{[1]} : \mathcal{C}^+[M] \to \mathcal{C}$.
4.7. MONADS AND THE BARR-BECK THEOREM

Proof. Let \( \mathcal{J} \) be the full subcategory of the product \( \Delta^1 \times N(Po_{[1]})^{op} \) obtained by removing the vertex (1, [1], 0, 0) and let \( \mathcal{J}_0 \subset \mathcal{J} \) be the full subcategory obtained by removing the vertex (0, [1], 0, 0). Let \( \mathcal{X}_0 \) be the full subcategory of \( \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\mathcal{J}_0, M^\otimes) \times_M \{ M \} \) spanned by the \( p \)-limit diagrams and let \( \mathcal{X} = \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\mathcal{J}, M^\otimes) \times_{\text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\mathcal{J}_0, M^\otimes)} \mathcal{X}_0 \). The map \( \theta_{[1]} \) factors as a composition of restriction functors
\[
\mathcal{C}^+[M] \to \mathcal{X} \times_M \{ M \} \to \mathcal{X}_0 \Rightarrow \mathcal{C},
\]
where \( \phi \) and \( \psi \) are trivial Kan fibrations by Proposition T.4.3.2.15. It will therefore suffice to show that \( \theta' \) is a right fibration. But \( \theta' \) is a pullback of the right fibration \( (M^\otimes)/M \to M^\otimes \).

Let \( M^\otimes \) and \( M \) be as above. For each \( n \geq 0 \) we can identify the map \( \theta_{[n]} : \mathcal{C}^+[M]_{[n]} \to \mathcal{C}^+_{} \) with the \( n \)-th power of the right fibration \( \theta_{[1]} \) of Lemma 4.7.2.36. The forgetful functor \( \mathcal{C}^+[M]^\otimes \to \mathcal{C}^+_{} \) is not a right fibration, but we have the following closely related result:

**Lemma 4.7.2.37.** Let \( p : M^\otimes \to \Delta^1 \times N(\Delta)^{op} \) be a map which exhibits \( M = M^\otimes_{0,0} \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{C}^\otimes = M^\otimes \times_{\Delta} \{ 1 \} \). Let \( M \in M \) be an object and let \( \theta : \mathcal{C}^+[M]^\otimes \to \mathcal{C}^+_{} \) be as in Remark 4.7.2.33. For each \( n \geq 0 \), every morphism \( f \) in \( \mathcal{C}^+[M]_{[n]} \) is \( \theta \)-Cartesian.

**Proof.** We begin with an auxiliary construction. Define a map of simplicial sets \( \mathcal{C}^\otimes \to N(\Delta)^{op} \) so that the following universal property is satisfied: for every map of simplicial sets \( K \to N(\Delta)^{op} \), there is a canonical bijection
\[
\text{Hom}_{(\text{Set}_\Delta)/N(\Delta)^{op}}(K, \mathcal{C}^\otimes) \cong \text{Hom}_{(\text{Set}_\Delta)/N(\Delta)^{op}}(\text{N}(\text{Po})^{op} \times N(\Delta)^{op} K, \mathcal{C}^\otimes).
\]

For each \( n \geq 0 \), the fiber \( \mathcal{C}^\otimes_{[n]} \) can be identified with \( \text{Fun}_{N(\Delta)^{op}}(\text{N}(\text{Po})_{[n]}^{op}, \mathcal{C}^\otimes) \); we let \( \mathcal{C}^\otimes_{[n]} \) denote the full subcategory of \( \mathcal{C}^\otimes \) spanned by those objects which correspond to functors \( F : \text{N}(\text{Po})_{[n]}^{op} \to \mathcal{C}^\otimes \) which are \( p \)-left Kan extensions of \( F|\{(n), 0, n\} \). Composition with the functor \( s : N(\Delta)^{op} \to N(\text{Po})^{op} \) given by \( [n] \mapsto ([n], 0, n) \) induces a restriction functor \( r : \mathcal{C}^\otimes \to \mathcal{C}^\otimes_{[n]} \).

We claim that \( r \) induces a trivial Kan fibration \( \mathcal{C}^\otimes \to \mathcal{C}^\otimes_{[n]} \). To prove this, we associate to every map of simplicial sets \( K \to N(\Delta)^{op} \) the fiber product \( \text{N}(\text{Po})_{K}^{op} = K \times_{N(\Delta)^{op}} \text{N}(\text{Po})^{op} \). Let \( M_K \) be the collection of all morphisms in \( \text{N}(\text{Po})_{K}^{op} \) whose image in \( K \) is degenerate. Then \( s \) determines a map of marked simplicial sets \( u_K : K^\otimes \to (\text{N}(\text{Po})_{K}^{op}, M_K) \). When \( K \) is a simplex, Proposition T.4.3.2.15 implies that \( u_K \) is a weak equivalence of marked simplicial sets. It follows by standard devissage argument that \( u_K \) is a weak equivalence of marked simplicial sets for every \( K \); in particular, every map \( \Delta^n \to N(\Delta)^{op} \) induces a trivial cofibration
\[
\Delta^n, b \coprod_{\partial \Delta^n} \text{N}(\text{Po})_{\partial \Delta^n}^{op}, M_{\partial \Delta^n}) \to (\text{N}(\text{Po})_{\partial \Delta^n}^{op}, M_{\partial \Delta^n}),
\]
from which it follows immediately that the map \( \mathcal{C}^\otimes \to \mathcal{C}^\otimes_{[n]} \) has the right lifting property with respect to \( \partial \Delta^n \to \Delta^n \).

The map \( \theta \) is a pullback of the restriction functor \( \overline{\theta} : \text{Str} M^{en,+} \to \text{Str} \mathcal{M} \times_{N(\Delta)^{op}} \mathcal{C}^\otimes \). It will therefore suffice to show that \( f \) is \( \overline{\theta} \)-Cartesian. Let \( \phi : \text{Str} M \times_{N(\Delta)^{op}} \mathcal{C}^\otimes \to \mathcal{C}^\otimes \), so that \( \phi \) is a pullback of the map \( \phi_0 : \text{Str} M \to N(\Delta)^{op} \). The image of \( f \) in \( \text{Str} M \) is an equivalence and therefore \( \phi_0 \)-Cartesian. It follows that \( \overline{\theta}(f) \) is \( \phi \)-Cartesian. Consequently, to prove that \( f \) is \( \overline{\theta} \)-Cartesian, it will suffice to show that \( f \) is \( (\phi \circ \overline{\theta}) \)-Cartesian (Proposition T.2.4.1.3). The map \( \phi \circ \overline{\theta} \) factors as a composition
\[
\text{Str} M^{en,+} \Rightarrow \overline{\theta} \Rightarrow \mathcal{C}^\otimes \Rightarrow \mathcal{C}^\otimes,
\]
where the second map is a trivial Kan fibration. It will therefore suffice to show that \( f \) is \( \psi \)-Cartesian.

Let \( f : X \to Y \) be a morphism in \( \text{Str} M_{[n]}^{en,+} \). Set \( \mathcal{J} = \Delta^1 \times N(\text{Po}_{[n]})^{op} \) and let \( \mathcal{J}_0 = \{ 1 \} \times N(\text{Po}_{[n]})^{op} \subseteq \mathcal{J} \). We can identify \( X \) and \( Y \) with functors \( \mathcal{J} \to M^\otimes \) and \( f \) with a functor \( F : \Delta^1 \times \mathcal{J} \to M^\otimes \). According
to Proposition B.4.9, it will suffice to show that $F$ is a $p$-right Kan extension of $F_0 = F|\mathcal{J}$, where $\mathcal{J} = (\Delta^1 \times \partial_0) \coprod_{\{1\} \times \partial_0} \{(1) \times \partial_0\}$. Fix an object of $E$ of $\Delta^1 \times \partial_0$ not belonging to $\mathcal{J}$ having image $([n], i, j)$ in $\Delta$; we will prove that $F$ is a $p$-right Kan extension of $F_0$ at $E$. That is, we show that $F$ exhibits $F(E)$ as a $p$-limit of the diagram $F_0|\langle \mathcal{J}_X \rangle$. Unwinding the definitions, we must show that the diagram

$$
\begin{array}{ccc}
X(0, [n], i, j) & \longrightarrow & Y(0, [n], i, j) \\
\downarrow & & \downarrow \\
X(1, [n], i, j) & \longrightarrow & Y(1, [n], i, j)
\end{array}
$$

is a $p$-limit square. Since $Y \in \text{Str}
\mathcal{M}_{[n]}^{en,+}$, it exhibits $Y(0, [n], i, j)$ as a $p$-product of $Y(1, [n], i, j)$ with $Y(0, [n], j, j)$. It will therefore suffice to show that $F$ exhibits $X(0, [n], i, j)$ as a $p$-product of $X(1, [n], i, j)$ with $X(0, [n], j, j) \simeq M \simeq X(0, [n], j, j)$, which follows from our assumption that $X \in \text{Str}
\mathcal{M}_{[n]}^{en,+}$.

\begin{remark}
In the situation of Lemma 4.7.2.36, the functor $\theta_{[1]} : \mathcal{C}^+[M] \to \mathcal{C}$ is conservative. It follows that for each $n \geq 0$, the functor $\theta_{[n]} : \mathcal{C}^+[M]_{[n]}^\otimes \to \mathcal{C}_{[n]}^\otimes$ is conservative, so that $\theta$ is itself conservative. In particular, we note that a morphism $\alpha$ in $\mathcal{C}^+[M]^\otimes$ is inert if and only if $\theta(\alpha)$ is an inert morphism in $\mathcal{C}_{[n]}^\otimes$.
\end{remark}

\begin{proposition}
Let $p : \mathcal{M}^\otimes \to \Delta^1 \times \mathcal{N}(\Delta)^{op}$ be a map which exhibits $\mathcal{M} = \mathcal{M}_{[0]}^\otimes$ as weakly enriched over the $\Delta$-planar $\infty$-operad $\mathcal{C}^{\otimes} = \mathcal{M}^{\otimes} \times_{\Delta^1} \{1\}$. For each object $M \in \mathcal{M}$, the forgetful functor $\theta : \mathcal{C}^+[M]^\otimes \to \mathcal{C}^\otimes$ induces a right fibration $^\Delta \text{Alg}(\mathcal{C}^+[M]) \to ^\Delta \text{Alg}(\mathcal{C})$.
\end{proposition}

\begin{proof}
Combine Remark 4.7.2.38 with Lemmas 4.7.2.36 and 4.7.2.37.
\end{proof}

\begin{corollary}
Let $p : \mathcal{M}^\otimes \to \Delta^1 \times \mathcal{N}(\Delta)^{op}$ be a coCartesian fibration which exhibits $\mathcal{M} = \mathcal{M}_{[0]}^\otimes$ as left-tensored over the $\Delta$-monoidal $\infty$-category $\mathcal{C}^{\otimes} = \mathcal{M}^{\otimes} \times_{\Delta^1} \{1\}$. Assume that the $\infty$-category $\mathcal{C}[M]$ has a final object $A$. Then:

1. The object $A$ can be promoted to an object of $^\Delta \text{Mod}(\mathcal{C}^+[M])$ in an essentially unique way. We will abuse notation by denoting this object also by $A$.

Let $\theta : ^\Delta \text{Alg}(\mathcal{C}^+[M]) \to ^\Delta \text{Alg}(\mathcal{C})$ be the forgetful functor. Then:

2. There is a canonical equivalence of $\infty$-categories $^\Delta \text{Alg}(\mathcal{C})_{/\theta(A)} \simeq ^\Delta \text{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{M\}$.
\end{corollary}

\begin{proof}
Proposition 4.7.2.30 implies that the forgetful functor $\mathcal{C}[^\Delta \text{Mod}(\mathcal{M})^\otimes \to \mathcal{N}(\Delta)^{op}$ exhibits $\mathcal{C}[M]^\otimes$ as a $\Delta$-monoidal $\infty$-category, so that $\mathcal{C}[M]^\otimes \simeq \mathcal{O}^\otimes \times_{\text{Ass}^\otimes} \mathcal{N}(\Delta)^{op}$ for some coCartesian fibration of $\infty$-operads $\mathcal{O}^\otimes \to \text{Ass}^\otimes$. Combining Corollary 3.2.2.5 with Proposition 4.1.2.15, we conclude that $A$ can be promoted to an object of $^\Delta \text{Alg}(\mathcal{C}[M])$, which is automatically a final object of $^\Delta \text{Alg}(\mathcal{C}[M])$ (and therefore unique up to equivalence). Since the map $^\Delta \text{Alg}(\mathcal{C}^+[M]) \to ^\Delta \text{Alg}(\mathcal{C}[M])$ is a trivial Kan fibration; we may lift $A$ to a final object of $^\Delta \text{Alg}(\mathcal{C}^+[M])$, which we will also denote by $A$. This proves (1). We have a diagram of maps

$$
^\Delta \text{Alg}(\mathcal{C})_{/\theta(A)} \leftarrow ^\Delta \text{Alg}(\mathcal{C}^+[M])_{/A} \to ^\Delta \text{Alg}(\mathcal{C}^+[M]) \to ^\Delta \text{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{M\}
$$

which are equivalences of $\infty$-categories by virtue of Proposition 4.7.2.39 and Theorem 4.7.2.34.
\end{proof}

\begin{corollary}
Let $p : \mathcal{M}^\otimes \to \Delta^1 \times \mathcal{N}(\Delta)^{op}$ be a coCartesian fibration which exhibits $\mathcal{M} = \mathcal{M}_{[0]}^\otimes$ as left-tensored over the $\Delta$-monoidal $\infty$-category $\mathcal{C}^{\otimes} = \mathcal{M}^{\otimes} \times_{\Delta^1} \{1\}$. Let $M \in ^\Delta \text{LMod}(\mathcal{M})$ be a left module object having images $M \in \mathcal{M}$ and $A \in ^\Delta \text{Alg}(\mathcal{C})$. Suppose that the multiplication map $A \otimes M \to M$ exhibits $A$ as a classifying object for endomorphisms of $M$. Then, for every algebra object $B \in ^\Delta \text{Alg}(\mathcal{C})$, we have a canonical isomorphism $\text{Map}_{^\Delta \text{Alg}(\mathcal{C})}(B, A) \simeq ^\Delta \text{LMod}_B(\mathcal{M}) \times_{\mathcal{M}} \{M\}$ in the homotopy category $\mathcal{K}$ of spaces.
\end{corollary}
Corollary 4.7.2.42. Let \( \mathcal{C} \) be a \( \Delta \)-monoidal \( \infty \)-category, \( \mathcal{M} \) an \( \infty \)-category which is left-tensored over \( \mathcal{C} \), and \( M \in \mathcal{M} \) an object. Then the forgetful functor
\[
\Delta \text{LMod}(\mathcal{M}) \times \mathcal{M} \{M\} \to \Delta \text{Alg}(\mathcal{C})
\]
is a right fibration.

Proof. Combine Proposition 4.7.2.39 with Theorem 4.7.2.34. \( \square \)

4.7.3 Split Simplicial Objects

Suppose we are given a chain complex of abelian groups
\[
\cdots \to A_2 \overset{d_2}{\to} A_1 \overset{d_1}{\to} A_0.
\]
An augmentation on \( A_* \) is a map of abelian groups \( d_0 : A_0 \to A_{-1} \) such that \( d_0 \circ d_1 = 0 \). We say that \( A_* \) is a split exact resolution of \( A_{-1} \) if there exists a contracting chain homotopy for the extended chain complex
\[
\cdots \to A_2 \overset{d_2}{\to} A_1 \overset{d_1}{\to} A_0 \overset{d_0}{\to} A_{-1}.
\]
That is, \( A_* \) is a split exact resolution of \( A_{-1} \) if there exist maps \( \{h_n : A_{n-1} \to A_n\}_{n \geq 0} \) such that \( d_0 h_0 = \text{id}_{A_{-1}} \) and \( d_{n+1} h_{n+1} + h_n d_n = \text{id}_{A_n} \) for \( n \geq 0 \). In this case, if we let \( Z_n \subseteq A_n \) be the kernel of the differential \( d_n \), then we have canonical isomorphisms \( A_n \cong Z_n \oplus Z_{n-1} \) for each \( n \geq 0 \), where the inclusion \( Z_{n-1} \to A_n \) is given by \( h_n \mid_{Z_{n-1}} \). This implies that the chain complex \( A_* \) is exact. In fact, a much stronger assertion is true: for any additive functor \( F \), the induced chain complex
\[
\cdots \to F(A_2) \to F(A_1) \to F(A_0) \to F(A_{-1})
\]
is exact, even if \( F \) is not an exact functor.

In the situation above, we can use the Dold-Kan correspondence (Theorem 1.2.3.7) to identify \( A_* \) with the normalized chain complex of a simplicial abelian group \( C_* \). It is possible to formulate the condition that \( A_* \) is a split exact resolution of an abelian group \( A_{-1} \) in terms of the simplicial abelian group \( C_* \). Moreover, this formulation makes sense not only for simplicial objects of the category of abelian groups, but for simplicial objects of an arbitrary \( \infty \)-category.

Notation 4.7.3.1. The category \( \Delta_{-\infty} \) is defined as follows: the objects of \( \Delta_{-\infty} \) are integers \( n \geq -1 \), and \( \text{Hom}_{\Delta_{-\infty}}([m], [n]) \) is the set of nondecreasing maps maps \( \alpha : [m] \cup \{-\infty\} \to [n] \cup \{-\infty\} \) such that \( \alpha(-\infty) = -\infty \) (which we regard as a least element of both \( [m] \cup \{-\infty\} \) and \( [n] \cup \{-\infty\} \)). We have inclusions of subcategories \( \Delta \subseteq \Delta_{+} \subseteq \Delta_{-\infty} \), where the latter identifies \( \Delta_{+} \) with the subcategory of \( \Delta_{-\infty} \) having the same objects, and a map \( \alpha : [m] \cup \{-\infty\} \to [n] \cup \{-\infty\} \) belongs to \( \Delta_{+} \) if and only if \( \alpha^{-1}(-\infty) = \{-\infty\} \).

Definition 4.7.3.2. Let \( \mathcal{C} \) be an \( \infty \)-category. We will say that an augmented simplicial object \( U : N(\Delta_{+})^{op} \to \mathcal{C} \) is split if \( U \) extends to a functor \( N(\Delta_{-\infty})^{op} \to \mathcal{C} \). We will say that a simplicial object \( U : N(\Delta)^{op} \to \mathcal{C} \) is split if it extends to a split augmented simplicial object. Given a functor \( G : \mathcal{D} \to \mathcal{C} \), we will say that an (augmented) simplicial object \( U \) of \( \mathcal{D} \) is \( G \)-split if \( G \circ U \) is split, when regarded as an (augmented) simplicial object of \( \mathcal{C} \).

Remark 4.7.3.3. According to Lemma T.6.1.3.16, every split augmented simplicial object is a colimit diagram. (In [97], we used a slightly different notation, employing a category \( \Delta_{\infty} \) in place of the category \( \Delta_{-\infty} \) defined above. However, these two categories are equivalent to one another, via the functor which reverses order.)

Remark 4.7.3.4. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor between \( \infty \)-categories, and let \( V \) be a split simplicial object of \( \mathcal{C} \). Then \( F \circ V \) is a split simplicial object of \( \mathcal{D} \). It follows from Lemma T.6.1.3.16 implies that \( V \) admits a colimit in \( \mathcal{C} \), and that \( F \) preserves that colimit.
**Example 4.7.3.5.** Let $\mathcal{C}$ be an $\infty$-category which is left tensored over a monoidal $\infty$-category $\mathcal{C}^\otimes$, let $A \in \text{Alg}(\mathcal{C})$, and $G : \text{LMod}_A(M) \to M$ denote the forgetful functor. Let $M_\bullet$ be a simplicial object of $\text{LMod}_A(M)$ which is $G$-split. Then $G(M_\bullet)$ admits a colimit in $M$ which is preserved by the functor $C \otimes \bullet : M \to M$ for each object $C \in \mathcal{C}$. Applying Corollary 4.2.3.5, we deduce that $M_\bullet$ admits a colimit in $\text{LMod}_A(M)$ which is preserved by the functor $G$.

**Variant 4.7.3.6.** Let $\mathcal{C}$ be an $\infty$-category which is bitensored over the a pair of monoidal $\infty$-categories $\mathcal{C}^\otimes$ and $\mathcal{D}^\otimes$, and suppose we are given algebra objects $A \in \text{Alg}(\mathcal{C})$ and $B \in \text{Alg}(\mathcal{D})$. Let $\theta : \text{RMod}_B(M) \to M$ denote the forgetful functor, and regard $\text{RMod}_B(M)$ as an $\infty$-category left-tensored over $\mathcal{C}$ (see §4.3.2). Let $\mu : A\text{BMod}_B(M) \simeq \text{LMod}_A(\text{RMod}_B(M)) \to \text{RMod}_B(M)$ be the forgetful functor, and let $M_\bullet$ be a simplicial object of $A\text{BMod}_B(M)$. Assume that $M_\bullet$ is $\theta \circ \mu$-split. Then $\mu(M_\bullet)$ is a $\theta$-split simplicial object of $\text{RMod}_B(M)$. It follows from Example 4.7.3.5 that $\mu(M_\bullet)$ admits a geometric realization in $\text{RMod}_B(M)$. For every object $C \in \mathcal{C}$, the diagram

$$
\begin{array}{ccc}
\text{RMod}_B(M) & \xrightarrow{C \otimes} & \text{RMod}_B(M) \\
\downarrow{\phi} & & \downarrow{\theta} \\
M & \xrightarrow{C \otimes} & M
\end{array}
$$

commutes up to homotopy. It follows that the formation of the geometric realization of $\mu(M_\bullet)$ is preserved by operation of tensor product with $C$. Applying Corollary 4.2.3.5, we deduce that $M_\bullet$ admits a geometric realization in $A\text{BMod}_B(M)$, which is preserved by the forgetful functor $\mu$. This proves the following:

\((\ast)\) Let $M_\bullet$ be $\nu$-split simplicial object of $A\text{BMod}_B(M)$, where $\nu = \theta \circ \mu : A\text{BMod}_B(M) \to M$ is the forgetful functor. Then $M_\bullet$ admits a geometric realization in $A\text{BMod}_B(M)$, which is preserved by the functor $\nu$.

**Example 4.7.3.7.** We define a functor $\phi : \mathcal{N}(\Delta_{-\infty})^{op} \to \mathcal{N}(\Delta)^{op}$ by the formula $\phi(\{-\infty\} \cup \{n\}) \simeq \{-\infty\} \star [n] * [0] \simeq \{n+1\}$, and let $\Phi : \mathcal{N}(\Delta_{-\infty})^{op} \to \mathcal{L}(\mathbb{C})$ be the composition of $\phi$ with the functor $\text{LCut} : \mathcal{N}(\Delta)^{op} \to \mathcal{L}(\mathbb{C})$ of Construction 4.2.2.6. Note that $\Phi(\{-\infty\}) = \mathbf{m}$. Since $\{-\infty\}$ is an initial object of $\Delta_{-\infty}$, there is a canonical natural transformation $\alpha : \Phi \to \Phi_0$, where $\Phi_0 : \mathcal{N}(\Delta_{-\infty})^{op} \to \mathcal{L}(\mathbb{C})$ is the constant functor taking the value $\mathbf{m}$.

Let $q : \mathbb{C} \to \mathcal{L}(\mathbb{C})$ be a coCartesian fibration of $\infty$-operads, corresponding to an $\infty$-category $M$ left-tensored over a monoidal $\infty$-category $\mathbb{C}^\otimes = \mathcal{M}_\mathbb{C}^\otimes$. Let $X : \mathcal{L}(\mathbb{C}) \to \mathbb{M}^\otimes$ be an object of $\text{LMod}(\mathbb{M})$. We can identify $X$ with a pair $(A,M)$, where $A$ is an algebra object of $\mathbb{C}$ and $M \in \mathbb{M}$ has the structure of a left module over $A$. The composition $X \circ \Phi$ is a functor $\mathcal{N}(\Delta_{-\infty})^{op} \to \mathbb{M}^\otimes$. Since $q$ is a coCartesian fibration, we can lift $\alpha$ to a $q$-coCartesian natural transformation $\overline{\alpha} : (X \circ \Phi) \to X'$ for some functor $X' : \mathcal{N}(\Delta_{-\infty})^{op} \to \mathbb{M}$. Unwinding the definitions, we see that $X' \mid \mathcal{N}(\Delta)^{op}$ is the bar construction $\text{Bar}_A(A,M)_\bullet$ of Construction 4.4.2.7. It follows that $\text{Bar}_A(A,M)_\bullet$ is a split simplicial object of $M$. Moreover, Remark 4.7.3.3 implies that $X' \mid \mathcal{N}(\Delta_{-\infty})^{op}$ is a colimit diagram, which produces another proof that $|\text{Bar}_A(A,M)_\bullet| \simeq X'(\{-\infty\}) = M$.

The construction $[n] \mapsto [0] * [n] \simeq [n+1]$ determines a functor $\rho$ from $\Delta_{+}$ to itself. There is an evident natural transformation $\alpha : \text{id}_{\Delta_{+}} \to \rho$. Let $j$ denote the inclusion $\Delta_{+} \hookrightarrow \Delta_{-\infty}$. There is another natural transformation of functors $\beta : j \circ \rho \to j$, which carries an object $[n] \in \Delta_{+}$ to the map $f : [n+1] \cup \{\{-\infty\}\} \to [n] \cup \{\{-\infty\}\}$ such that $f(0) = \infty$ and $f(k) = k - 1$ for $0 < k \leq n + 1$. The composition of $j(\alpha)$ and $\beta$ is the identity natural transformation from the functor $j$ to itself. We can view $j(\alpha)$ and $\beta$ as determining a map of simplicial sets $\mathcal{N}(\Delta_{+}) \times \Delta^{2} \to \mathcal{N}(\Delta_{-\infty})$.

**Proposition 4.7.3.8.** The diagram

$$
\begin{array}{ccc}
\mathcal{N}(\Delta_{+}) \times \Delta^{0} & \xrightarrow{\Delta^{0}} & \mathcal{N}(\Delta_{+}) \\
\downarrow & & \downarrow \\
\mathcal{N}(\Delta_{+}) \times \Delta^{2} & \xrightarrow{\Delta^{2}} & \mathcal{N}(\Delta_{-\infty})
\end{array}
$$
is a homotopy pushout square of simplicial sets (with respect to the Joyal model structure).

**Proof.** Let $f : [m] \cup \{-\infty\} \to [n] \cup \{-\infty\}$ be a morphism in $\Delta_{-\infty}$. We define the complexity $c(f)$ to be the cardinality of the set $\{i \in [m] : f(i) = \infty\}$. If $\sigma$ is an $k$-simplex of $N(\Delta_{-\infty})$ corresponding to a sequence of maps $[n_0] \cup \{-\infty\} \xrightarrow{f_1} \cdots \xrightarrow{f_k} [n_k] \cup \{-\infty\}$, then we define the complexity $c(\sigma)$ to be the sum $c(f_1) + \cdots + c(f_k)$. For every nonnegative integer $m$, let $X(m)$ denote the simplicial subset of $N(\Delta_{-\infty})$ spanned by those simplices $\sigma$ such that $c(\sigma) \leq m$. We note that $X(0)$ can be identified with $N(\Delta_+) \cup \{-\infty\}$, and that $N(\Delta_{-\infty}) = \bigcup_m X(m)$.

Proposition 4.7.3.8 follows immediately from the following pair of assertions:

(a) The diagram

\[
\begin{array}{ccc}
N(\Delta_+) \times \Lambda_0^2 & \longrightarrow & N(\Delta_+) \\
\downarrow & & \downarrow \\
N(\Delta_+) \times \Delta^2 & \longrightarrow & X(1)
\end{array}
\]

is a homotopy pushout square of simplicial sets (with respect to the Joyal model structure).

(b) For $n \geq 2$, the inclusion $X(n-1) \hookrightarrow X(n)$ is a categorical equivalence.

The proofs of both (a) and (b) will require some auxiliary constructions. Let $F_1, \ldots, F_k$ be a sequence of functors from $\Delta_+$ to itself (in practice, each of these functors will be either $\rho$ or the identity). We define a category $\mathcal{C}[F_1, \ldots, F_k]$ as follows:

(i) An object of $\mathcal{C}[F_1, \ldots, F_k]$ is a pair $([n], i)$, where $[n] \in \Delta_+$ and $0 \leq i \leq k$.

(ii) If $i \leq j$, a morphism from $([n], i) \to ([n], j)$ in $\mathcal{C}[F_1, \ldots, F_k]$ is a map $[m] \to F_{i+1} \cdots F_j [n]$ in $\Delta_+$. If $i > j$, there are no morphisms from $([m], i)$ to $([n], j)$ in $\mathcal{C}[F_1, \ldots, F_k]$.

We now prove (a). The natural transformation $\beta : j \rho \to j$ determines a map $N(\mathcal{C}[\rho]) \to N(\Delta_{-\infty})$, which factors through the simplicial subset $X(1)$. This map fits into a commutative diagram

\[
\begin{array}{ccc}
N(\Delta_+) \times \Lambda_0^2 & \longrightarrow & N(\mathcal{C}[\mathrm{id}]) \\
\downarrow & & \downarrow \\
N(\Delta_+) \times \Delta^2 & \longrightarrow & N(\mathcal{C}[\rho]) \\
\downarrow & & \downarrow \\
x(1) & \longrightarrow & X(1)
\end{array}
\]

where the right hand square is a pushout square and therefore (since the vertical maps are all cofibrations) a homotopy pushout square. It will therefore suffice to show that the left square is a homotopy pushout diagram. This square fits into a larger diagram

\[
\begin{array}{ccc}
N(\Delta_+) \times \Delta^{(0,1)} & \xrightarrow{\theta} & N(\Delta_+) \\
\downarrow & & \downarrow \\
N(\Delta_+) \times \Lambda_0^2 & \longrightarrow & N(\mathcal{C}[\mathrm{id}]) \\
\downarrow & & \downarrow \\
N(\Delta_+) \times \Delta^2 & \longrightarrow & N(\mathcal{C}[\rho])
\end{array}
\]
where the upper square is a pushout diagram and therefore (since the vertical maps are again cofibrations) a homotopy pushout square; here the map $\theta$ classifies the natural transformation $\alpha : \text{id} \to \rho$. It therefore suffices to show that the outer square is a homotopy pushout. This square fits into a larger diagram

\[
\begin{array}{c}
N(\Delta_+) \times \{1\} \rightarrow N(\Delta_+) \times \Delta^{(0.1)} \rightarrow \beta \rightarrow N(\Delta_+) \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
N(\Delta_+) \times \Delta^{(1.2)} \rightarrow N(\Delta_+) \times \Delta^2 \rightarrow N(\mathcal{C}[\rho]).
\end{array}
\]

The left square is obviously a homotopy pushout diagram, and the outer rectangle is a homotopy pushout diagram by Proposition T.3.2.2.7. It follows that the right square is a homotopy pushout diagram, as desired.

We now prove (b). Fix $n \geq 2$. For every subset $S \subseteq \{1, \ldots, n\}$, let $Y_S = \mathcal{C}[F_1, \ldots, F_n]$ where

\[
F_i = \begin{cases}
\rho & \text{if } i \in S \\
\text{id}_{\Delta_+} & \text{if } i \notin S.
\end{cases}
\]

The natural transformation $\alpha : \text{id}_{\Delta_+} \to \rho$ determines inclusion functors $\mathcal{C}_S \to \mathcal{C}_{S'}$ for $S \subseteq S'$. Let $Y = N(\mathcal{C}_{\{1, \ldots, n\}})$ and let $Y_S = N(\mathcal{C}_S)$ for $S \subseteq \{1, \ldots, n\}$, so that we can identify each $Y_S$ with a simplicial subset of $Y$. Let $P$ be the collection of all subsets $S \subseteq \{1, \ldots, n\}$ and $P_0 \subset P$ the collection of all proper subsets $S \subset \{1, \ldots, n\}$. Let $Y' = \bigcup_{S \in P_0} Y_S \subseteq Y$. The diagram $S \mapsto Y_S$ is projectively cofibrant, so we can identify $Y'$ with a homotopy colimit of the diagram $\{Y_S\}_{S \in P_0}$. There is an evident pushout diagram of simplicial sets

\[
\begin{array}{c}
Y' \quad \rightarrow \quad Y \\
\downarrow \quad \downarrow \quad \downarrow \\
X(n-1) \quad \rightarrow \quad X(n).
\end{array}
\]

Consequently, to prove that the inclusion $X(n-1) \hookrightarrow X(n)$ is a categorical equivalence, it will suffice to show that the inclusion $Y' \hookrightarrow Y$ is a categorical equivalence. In other words, we are reduced to proving that the diagram $\{Y_S\}_{S \in P}$ is a homotopy colimit diagram (with respect to the Joyal model structure).

There is an obvious forgetful functor $Y \to \Delta^n$. For every simplicial subset $K \subseteq \Delta^n$, let $Z_K : P \to \text{Set}_\Delta$ be the functor given by the formula $Z_K(S) = Y_S \times_{\Delta^n} K$. We wish to prove that $Z_{\Delta^n}$ is a homotopy colimit diagram. Let $K_0 = \Delta^{[0,1]} \coprod_i \Delta^{[1,2]} \coprod [2] \cdots \coprod [n-1] \Delta^{[n-1,n]}$, so that the inclusion $K_0 \hookrightarrow \Delta^n$ is a categorical equivalence. Since each of the projection maps $Y_S \to \Delta^n$ is a Cartesian fibration, we deduce that the inclusion $Z_{K_0} \to Z_{\Delta^n}$ is a weak equivalence of diagrams (Proposition T.3.3.1.3). It will therefore suffice to show that $Z_{K_0}$ is a homotopy colimit diagram. Since the collection of homotopy colimit diagrams in $\text{Set}_\Delta$ is stable under the formation of homotopy pushout squares, we can deduce further to proving that $Z_K$ is a homotopy colimit diagram when $K = \{i\} \subseteq \Delta^n$ for $0 \leq i \leq n$ or $K = \Delta^{(i-1,i)} \subseteq \Delta^n$ for $0 < i \leq n$. In the first case, this is obvious: the diagram $Z_{\{i\}}$ is isomorphic to the constant diagram taking the value $N(\Delta_+$), which is a homotopy colimit diagram because the simplicial set $N(P_0)$ is weakly contractible (since $P_0$ has a least element $\emptyset \subset \{1, \ldots, n\}$). To handle the second, let us suppose that $K = \Delta^{(i-1,i)}$, so that $Z_K$ is given by the formula

\[
Z_K(S) = \begin{cases}
N(\mathcal{C}[\rho]) & \text{if } i \in S \\
N(\mathcal{C}[\text{id}]) & \text{otherwise}.
\end{cases}
\]

Let $P_1$ be the subset of $P_0$ consisting of the subsets $\emptyset, \{i\} \subset \{1, \ldots, n\}$. We observe that $Z_K|P_0$ is a homotopy left Kan extension of $Z_K|P_1$. Consequently, to prove that $Z_K$ is a homotopy colimit diagram, it suffices to show that $Z_K$ exhibits $Z_K(\{1, \ldots, n\})$ as a homotopy colimit of the restriction $Z_K|P_1$. Since $P_1$ has a final object $\{i\}$, this follows from the observation that the map $Z_K(\{i\}) \to Z_K(\{1, \ldots, n\})$ is a categorical equivalence (in fact, an isomorphism) of simplicial sets. \qed
Corollary 4.7.3.9. Let \( \mathcal{C} \) be an \( \infty \)-category, and let \( X_* \) be an augmented simplicial object of \( \mathcal{C} \). The following conditions are equivalent:

1. The augmented simplicial object \( X_* \) is split.
2. The canonical map \( TX_* \to X_* \) admits a right homotopy inverse.

Remark 4.7.3.10. More precisely, we see that if \( X_* \) is an augmented simplicial object of an \( \infty \)-category \( \mathcal{C} \), then extending \( X_* \) to a functor \( \text{N}(\Delta_{-\infty}^{op}) \to \mathcal{C} \) is equivalent to giving a natural transformation \( X_* \to TX_* \) together with a homotopy of the composite map

\[
X_* \to TX_* \to X_*
\]

with the identity on \( X_* \).

Corollary 4.7.3.11. Let \( f : \overline{\mathcal{C}} \to \mathcal{C} \) be a right fibration of \( \infty \)-categories and let \( \overline{C}_* \) be a simplicial object of \( \overline{\mathcal{C}} \). If \( f(\overline{C}_*) \) is a split simplicial object of \( \mathcal{C} \), then \( \overline{C}_* \) is a split simplicial object of \( \overline{\mathcal{C}}_* \).

Example 4.7.3.12. Let \( \mathcal{C} \) be an abelian category. Then Dold-Kan correspondence establishes an equivalence of categories between the category \( \text{Fun}(\Delta^{op}, \mathcal{C}) \) of simplicial objects of \( \mathcal{C} \) and the category \( \text{Ch}_{\geq 0}(\mathcal{C}) \) of nonnegatively graded chain complexes in \( \mathcal{C} \) (see, for example, [160]). Let \( X_* \) be a simplicial object of \( \mathcal{C} \), and let

\[
\cdots \to C_2 \xrightarrow{d_2} C_1 \xrightarrow{d_1} C_0
\]

be the corresponding (normalized) chain complex. Then extending \( X_* \) to an augmented simplicial object \( \overline{X}_* : \Delta^{op} \to \mathcal{C} \) is equivalent to providing an augmentation on the chain complex \( C_* \): that is, providing a map \( d_0 : C_0 \to C_{-1} \) such that \( d_0 \circ d_1 = 0 \). In this case, the augmented simplicial object \( TX_* \) corresponds to the cone

\[
\cdots \to C_3 \oplus C_2 \to C_2 \oplus C_1 \to C_1 \oplus C_0 \to C_0.
\]

Giving a section of the canonical map \( T\overline{X}_* \to \overline{X}_* \) is equivalent to giving a collection of maps \( h_n : C_{n-1} \to C_n \) satisfying \( d_0 h_0 = \text{id}_{C_{-1}} \) and \( d_{n+1} h_{n+1} + h_n d_n = \text{id}_{C_n} \) for \( n \geq 0 \). In other words, extending \( X_* \) to a split simplicial object of \( \mathcal{C} \) is equivalent to giving a contracting homotopy which exhibits \( C_* \) as a split exact resolution of some object \( C_{-1} \in \mathcal{C} \).

For later use, we record some other consequences of Proposition 4.7.3.8.

Corollary 4.7.3.13. Let \( \mathcal{C} \) be an \( \infty \)-category, and let \( \mathcal{X} \) denote the full subcategory of \( \text{Fun}(\text{N}(\Delta^{op}), \mathcal{C}) \) spanned by the split augmented simplicial objects of \( \mathcal{C} \) (that is, \( \mathcal{X} \) is the essential image of the restriction functor \( \text{Fun}(\text{N}(\Delta^{op}_{\infty}), \mathcal{C}) \to \text{Fun}(\text{N}(\Delta^{op}), \mathcal{C}) \)). Then \( \mathcal{X} \) is stable under retracts in \( \text{Fun}(\text{N}(\Delta^{op}_{\infty}), \mathcal{C}) \).

Proof. Suppose we have a commutative diagram

\[
\begin{array}{ccc}
X_* & \xrightarrow{\alpha} & Y_* \\
\downarrow{\beta} & \searrow{\text{id}} & \\
Y_* & \xrightarrow{\gamma} & Y_*
\end{array}
\]

of augmented simplicial objects of \( \mathcal{C} \), where \( X_* \) is split. We wish to prove that \( Y_* \) is split. According to Corollary 4.7.3.9, there exists a map of augmented simplicial objects \( \gamma : X_* \to TX_* \) such that the composition \( X_* \to TX_* \to X_* \) is homotopic to the identity. Let \( \gamma' \) denote the composition

\[
Y_* \xrightarrow{\alpha} X_* \xrightarrow{\gamma} TX_* \xrightarrow{T\beta} TY_*.\]
A simple diagram chase shows that the composition $Y_\bullet \xrightarrow{\gamma} TY_\bullet \to Y_\bullet$ is homotopic to the identity, so that $Y_\bullet$ splits as required. \qed

**Remark 4.7.3.14.** The functor $\rho$ carries $\Delta_+$ into the subcategory $\Delta \subseteq \Delta_+$. Consequently, the translation functor $T$ factors through a functor $\text{Fun}(N(\Delta^{op}), \mathcal{C}) \to \text{Fun}(N(\Delta^{op}), \mathcal{C})$. We will abuse notation and denote this functor also by $T$.

**Corollary 4.7.3.15.** Let $\mathcal{C}$ be an $\infty$-category, and let $X_\bullet$ be an augmented simplicial object of $\mathcal{C}$. The following conditions are equivalent:

1. The augmented simplicial object $X_\bullet$ is split.

2. There exists a simplicial object $U_\bullet$ of $\mathcal{C}$ such that $X_\bullet$ is a retract of $TU_\bullet$ (in the $\infty$-category of augmented simplicial objects of $\mathcal{C}$).

**Proof.** The implication (1) $\Rightarrow$ (2) follows from Corollary 4.7.3.9. We will prove that (2) $\Rightarrow$ (1). Using Corollary 4.7.3.13, we may assume that $X_\bullet = TU_\bullet$. The desired result in this case follows from the observation that the shift functor $\rho : \Delta_+ \to \Delta$ extends naturally to a functor $\Delta_{\infty} \to \Delta$, determined by the natural identification of linearly ordered sets $[n+1] = [0] \star [n] \simeq [n] \cup \{-\infty\}$.

### 4.7.4 The Barr-Beck Theorem

Let $G : \mathcal{D} \to \mathcal{C}$ be a functor between $\infty$-categories which admits a left adjoint $F$. Our goal in this section is to show that the composition $G \circ F \in \text{Fun}(\mathcal{C}, \mathcal{C})$ can be promoted to a monad $T \in \text{Alg}(\text{End}(\mathcal{C}))$ on $\mathcal{C}$ (Definition 4.7.0.1), that $G$ factors through a functor $G' : \mathcal{D} \to \text{LMod}_T(\mathcal{C})$ of (left) $T$-module objects of $\mathcal{C}$, and to give necessary and sufficient conditions for the functor $G'$ to be an equivalence of $\infty$-categories (Theorem 4.7.4.5).

We begin by noting that for any pair of $\infty$-categories $\mathcal{C}$ and $\mathcal{D}$, the $\infty$-category $\text{Fun}(\mathcal{D}, \mathcal{C})$ carries a left action of the simplicial monoid $\text{Fun}(\mathcal{C}, \mathcal{C})$. We regard the $\infty$-category as left-tensored over the monoidal $\infty$-category $\text{End}(\mathcal{C})^{\otimes}$. The essential observation is the following:

**Lemma 4.7.4.1.** Let $G : \mathcal{D} \to \mathcal{C}$ be a functor between $\infty$-categories. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor and let $v : F \circ G \to \text{id}_D$ be the counit of an adjunction between $F$ and $G$. Then $v$ induces a map

$$(G \circ F) \circ G = G \circ (F \circ G) \xrightarrow{\alpha} G \circ \text{id}_D = G$$

which exhibits $G \circ F \in \text{Fun}(\mathcal{C}, \mathcal{C})$ as a classifying object for endomorphisms of $G \in \text{Fun}(\mathcal{D}, \mathcal{C})$.

**Proof.** We wish to show that for every functor $U : \mathcal{C} \to \mathcal{C}$, composition with $v$ induces a homotopy equivalence $\alpha : \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{C})}(U, G \circ F) \to \text{Map}_{\text{Fun}(\mathcal{D}, \mathcal{C})}(U \circ G, G)$. Let $u : \text{id}_C \to G \circ F$ be the unit for an adjunction which is compatible with $v$. Then $u$ determines a map $\beta : \text{Map}_{\text{Fun}(\mathcal{D}, \mathcal{C})}(U \circ G, G) \to \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{C})}(U, G \circ F)$ given by the composition

$$\text{Map}_{\text{Fun}(\mathcal{D}, \mathcal{C})}(U \circ G, G) \to \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{C})}(U \circ G \circ F, G \circ F) \xrightarrow{\alpha_u} \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{C})}(U, G \circ F).$$

From the compatibility between $u$ and $v$, it follows readily that $\beta$ is a homotopy inverse to $\alpha$. \qed

**Definition 4.7.4.2.** Let $G : \mathcal{D} \to \mathcal{C}$ be a functor between $\infty$-categories. A *endomorphism monad* consists of a monad $T \in \text{Alg}(\text{End}(\mathcal{C}))$ together with a left $T$-module $\overline{G} \in \text{LMod}_T(\text{Fun}(\mathcal{D}, \mathcal{C}))$ whose image in $\text{Fun}(\mathcal{D}, \mathcal{C})$ coincides with $G$, such that the composition map $T \circ G \to G$ exhibits $T$ as a classifying object for endomorphisms of $G$.

In the situation of Definition 4.7.4.2, we will say that $\overline{G}$ exhibits $T$ as an endomorphism monad of $G$. Combining Lemma 4.7.4.1, Theorem 4.7.2.34, and Corollary 3.2.2.5, we obtain the following result:
Proposition 4.7.4.3. Let $G : \mathcal{D} \to \mathcal{C}$ be a functor between $\infty$-categories. Assume that there exists a functor $F : \mathcal{C} \to \mathcal{D}$ and a natural transformation $u : \text{id}_\mathcal{C} \to G \circ F$ which is the unit for an adjunction between $G$ and $F$. Then:

1. There exists an endomorphism monad for $G$.
2. Let $T$ be a monad on $\mathcal{C}$ and let $\overline{G} \in \text{LMod}_T(\text{Fun}(\mathcal{D}, \mathcal{C}))$ be a lifting of $G$. Then $\overline{G}$ exhibits $T$ as an endomorphism monad of $G$ if and only if the composite map

\[
T \xrightarrow{id_T \times u} T \circ G \circ F \xrightarrow{a \times \text{id}_F} G \circ F
\]

is an equivalence in $\text{Fun}(\mathcal{C}, \mathcal{C})$, where $a : T \circ G \to G$ denotes the action of $T$ on $G$.

Suppose that $G : \mathcal{D} \to \mathcal{C}$ is a functor between $\infty$-categories which is a left module over a monad $T \in \text{Alg}(\text{End}(\mathcal{C}))$. The left action of $T$ on $G$ determines a functor $G' : \mathcal{D} \to \text{LMod}_T(\mathcal{C})$ such that $G$ is obtained by composing $G'$ with the forgetful functor $\text{LMod}_T(\mathcal{C}) \to \mathcal{C}$.

Definition 4.7.4.4. Let $G : \mathcal{D} \to \mathcal{C}$ be a functor between $\infty$-categories. Assume that $G$ has a left adjoint $F$, so that $G$ admits an endomorphism monad $T$ (Proposition 4.7.4.3). We will say that $\mathcal{D}$ is monadic over $\mathcal{C}$ if the induced functor $G' : \mathcal{D} \to \text{LMod}_T(\mathcal{C})$ is an equivalence of $\infty$-categories.

If $G : \mathcal{D} \to \mathcal{C}$ exhibits the $\infty$-category $\mathcal{D}$ as monadic over the $\infty$-category $\mathcal{C}$, then we can think of $G$ as a forgetful functor: an object $D \in \mathcal{D}$ can be identified with its image $G(D) \in \mathcal{C}$, together with the data of an action of the endomorphism monad $T$ of the functor $G$.

We are now ready to state the main result of this section (which can be regarded as a more precise version of Theorem 4.7.0.3):

Theorem 4.7.4.5 ($\infty$-Categorical Barr-Beck Theorem). Let $G : \mathcal{D} \to \mathcal{C}$ be a functor between $\infty$-categories which admits a left adjoint $F : \mathcal{C} \to \mathcal{D}$. The following are equivalent:

(a) The functor $G$ exhibits $\mathcal{D}$ as monadic over $\mathcal{C}$.

(b) There exists a monoidal $\infty$-category $\mathcal{E}^\otimes$, a left action of $\mathcal{E}^\otimes$ on $\mathcal{C}$, an algebra object $A \in \text{Alg}(\mathcal{E})$ and an equivalence $G' : \mathcal{D} \simeq \text{LMod}_A(\mathcal{C})$ such that $G$ is equivalent to the composition of $G'$ with the forgetful functor $\text{LMod}_A(\mathcal{C}) \to \mathcal{C}$.

(c) The functor $G$ satisfies the following conditions:

1. The functor $G : \mathcal{D} \to \mathcal{C}$ is conservative; that is, a morphism $f : D \to D'$ in $\mathcal{D}$ is an equivalence if and only if $G(f)$ is an equivalence in $\mathcal{C}$.

2. Let $V$ be a simplicial object of $\mathcal{D}$ which is $G$-split. Then $V$ admits a colimit in $\mathcal{D}$, and that colimit is preserved by $G$.

Remark 4.7.4.6. For a proof of Theorem 4.7.4.5 in the setting of classical category theory, we refer the reader to [9].

Remark 4.7.4.7. Hypotheses (1) and (2) of Theorem 4.7.4.5 can be rephrased as the following single condition:

(*) Let $V : N(\Delta)^{op} \to \mathcal{D}$ be a simplicial object of $\mathcal{D}$ which is $G$-split. Then $V$ has a colimit in $\mathcal{D}$. Moreover, an arbitrary extension $\overline{V} : N(\Delta)^{op} \to \mathcal{D}$ is a colimit diagram if and only if $G \circ \overline{V}$ is a colimit diagram.

It is clear that (1) and (2) imply (*), and that (*) implies (2). To prove that (*) implies (1), let us consider an arbitrary morphism $f : D' \to D$ in $\mathcal{D}$. The map $f$ determines an augmented simplicial object $\overline{V}$ of $\mathcal{D}$, with

\[
\overline{V}([n]) = \begin{cases} 
D' & \text{if } n \geq 0 \\
D & \text{if } n = -1.
\end{cases}
\]
The underlying simplicial object \( V = \nabla | N(\Delta)^{\text{op}} \) is constant, and therefore \( G \)-split. Since \( N(\Delta) \) is contractible, \( \nabla \) is a colimit diagram if and only if \( f \) is an equivalence, and \( G \circ \nabla \) is a colimit diagram if and only if \( G(f) \) is an equivalence. If \((*)\) is satisfied, then these conditions are equivalent, so that \( G \) is conservative as desired.

**Remark 4.7.4.8.** Let \( \mathcal{C} \) be an \( \infty \)-category, and regard \( \mathcal{C} \) as left-tensored over the monoidal \( \infty \)-category \( \text{End}(\mathcal{C}) \). We have a commutative diagram

\[
\begin{array}{ccc}
\text{LMod}(\mathcal{C}) & \xrightarrow{\theta} & \mathcal{C} \times \text{Alg}(\text{End}(\mathcal{C})) \\
p & & p' \\
\text{Alg}(\text{End}(\mathcal{C})), & & \\
\end{array}
\]

where \( \theta \) is determined by the \( p \) and the forgetful functor \( \text{LMod}(\mathcal{C}) \to \mathcal{C} \). The functor \( p' \) is obviously a Cartesian fibration, and Corollary 4.2.3.2 implies that \( p \) is a Cartesian fibration as well. Proposition 4.2.3.1 implies that \( \theta \) carries \( p \)-Cartesian edges to \( p' \)-Cartesian edges. Consequently, \( \theta \) classifies a natural transformation of functors \( F \to F' \), where \( F : \text{Alg}(\text{End}(\mathcal{C}))^{\text{op}} \to \text{Cat}_\infty \) is the functor classified by \( p \) (so that \( F(A) \simeq \text{LMod}_T(\mathcal{C}) \) for every monad \( T \in \text{Alg}(\text{End}(\mathcal{C})) \)) and \( F' \) is the constant functor taking the value \( \mathcal{C} \in \text{Cat}_\infty \). We may identify this transformation with a functor \( \alpha : \text{Alg}(\text{End}(\mathcal{C}))^{\text{op}} \to \text{Cat}_\mathcal{C}^{/} \). We can interpret Theorem 4.7.4.5 as describing the essential image of the functor \( \alpha \): namely, a functor \( G : \mathcal{D} \to \mathcal{C} \) belongs to the essential image of \( \alpha \) if and only if \( G \) admits a left adjoint and satisfies conditions \((1)\) and \((2)\) of Theorem 4.7.4.5. With more effort, one can show that the functor \( \alpha \) is fully faithful. In other words, we may identify monads on \( \mathcal{C} \) with (certain) \( \infty \)-categories lying over \( \mathcal{C} \).

**Example 4.7.4.9.** Let \( \mathcal{M} \) be an \( \infty \)-category which is bitensored over the a pair of monoidal \( \infty \)-categories \( \mathcal{C}^{\otimes} \) and \( \mathcal{D}^{\otimes} \), and suppose we are given algebra objects \( A \in \text{Alg}(\mathcal{C}) \) and \( B \in \text{Alg}(\mathcal{D}) \). Let \( G : \text{AMod}_B(\mathcal{M}) \to \mathcal{M} \) be the forgetful functor. Corollary 4.3.3.13 implies that \( G \) admits a left adjoint, Corollary 4.3.3.2 implies that \( G \) is conservative, and Variant 4.7.3.6 implies that every \( G \)-split simplicial object of \( \text{AMod}_B(\mathcal{M}) \) admits a colimit which is preserved by \( G \). Using Theorem 4.7.4.5, we deduce that \( G \) exhibits \( \text{AMod}_B(\mathcal{M}) \) as monadic over \( \mathcal{M} \). The underlying monad \( T : \mathcal{M} \to \mathcal{M} \) is given by \( M \mapsto A \otimes M \otimes B \).

**Example 4.7.4.10.** Let \( G : \mathcal{D} \to \mathcal{C} \) be a functor between \( \infty \)-categories which exhibits \( \mathcal{D} \) as monadic over \( \mathcal{C} \). Assume that \( \mathcal{D} \) and \( \mathcal{C} \) admit finite limits. The functor \( G \) is left exact, and therefore induces a functor \( g : \text{Sp}(\mathcal{D}) \to \text{Sp}(\mathcal{C}) \). Suppose that \( g \) admits a left adjoint. Then \( g \) exhibits \( \text{Sp}(\mathcal{D}) \) as monadic over \( \text{Sp}(\mathcal{C}) \). To prove this, we show that \( g \) satisfies the hypotheses of Theorem 4.7.4.5:

1. The functor \( g \) is conservative.
2. If \( U_\bullet \) is a simplicial object of \( \text{Sp}(\mathcal{D}) \) which is \( g \)-split, then \( U_\bullet \) admits a colimit in \( \text{Sp}(\mathcal{D}) \), and that colimit is preserved by \( g \).

Assertion \((1)\) follows immediately from our assumption that \( G \) is conservative. We now prove \((2)\). Let \( U_\bullet \) be a \( g \)-split simplicial object of \( \text{Sp}(\mathcal{D}) \). For each \( K \in \text{Sp}_n(\mathcal{D}) \), \( U_\bullet(K) \) is a \( g \)-split simplicial object of \( \mathcal{D} \). It follows from Theorem 4.7.4.5 that \( U_\bullet(K) \) admits a colimit \( V(K) \in \mathcal{D} \), which is preserved by the functor \( G \). The construction \( K \mapsto V(K) \) determines a functor \( V : \text{Sp}_n(\mathcal{D}) \to \mathcal{D} \), where \( G \circ V \simeq |g(U_\bullet)| \) is reduced and excisive. Since \( G \) is left exact and conservative, we deduce that \( V \) is left exact and excisive. It follows that \( V \in \text{Sp}(\mathcal{D}) \). Since \( V \) is a colimit of the diagram \( U_\bullet \) in \( \text{Fun}(\text{Sp}_n(\mathcal{D}), \mathcal{D}) \), it is a colimit of the diagram \( U_\bullet \) in \( \text{Sp}(\mathcal{D}) \). By construction, this colimit is preserved by the functor \( g \).

**Example 4.7.4.11.** Let \( \mathcal{O} : \mathcal{O}^{\otimes} \to \mathcal{O}^{\otimes} \) be a coCartesian fibration of \( \infty \)-operads and let \( \mathcal{O}_{\mathcal{C}}^{\otimes} \to \mathcal{O}^{\otimes} \) be a map of \( \infty \)-operads which is essentially surjective. Assume that:

1. For each object \( X \in \mathcal{O} \), the \( \infty \)-category \( \mathcal{O}_X \) admits geometric realizations of simplicial objects.
4.7. MONADS AND THE BARR-BECK THEOREM

(b) For each operation $\alpha \in \text{Mul}_G(\{X_i\}, Y)$, the induced functor $\prod \mathcal{C}_{X_i} \to \mathcal{C}_Y$ preserves geometric realizations of simplicial objects.

(c) The forgetful functor $p : \text{Alg}_G(\mathcal{C}) \to \text{Alg}_{G'}(\mathcal{C})$ admits a left adjoint.

Then $p$ exhibits $\text{Alg}_G(\mathcal{C})$ as monadic over $\text{Alg}_{G'}(\mathcal{C})$. This follows immediately from Theorem 4.7.0.3 and Proposition 3.2.3.1.

We now turn to the proof of Theorem 4.7.4.5. The implication $(a) \Rightarrow (b)$ is obvious (take $\mathcal{E} = \text{End}(\mathcal{C})$ and $A$ to be an endomorphism monad of $G$). The implication $(b) \Rightarrow (c)$ follows immediately from Corollary 4.2.3.2 together with the following:

**Lemma 4.7.4.12.** Let $\mathcal{C}$ be a monoidal $\infty$-category, $\mathcal{M}$ an $\infty$-category which is left-tensored over $\mathcal{C}$, $A$ an algebra object, and $\theta : \text{LMod}_A(\mathcal{M}) \to \mathcal{M}$ the forgetful functor. Then:

1. Every $\theta$-split simplicial object of $\text{LMod}_A(\mathcal{M})$ admits a colimit in $\mathcal{M}$.
2. The functor $\theta$ preserves colimits of $\theta$-split simplicial objects.

**Proof.** Let $\mathcal{M}^\otimes \to \mathcal{C}^\otimes$ be defined as in Notation 4.2.2.16. In view of Proposition 4.2.2.11, it will suffice to prove the analogues of (1) and (2) for the forgetful functor $\Delta \text{LMod}_A(\mathcal{M}) \to \mathcal{M}$. Note that a simplicial object of $\Delta \text{LMod}_A(\mathcal{M})$ can be viewed as a bisimplicial object of $\mathcal{M}^\otimes$. In order to avoid confusion, we let $K$ denote the simplicial set $N(\Delta)^{op}$ when we wish to emphasize the role of $N(\Delta)^{op}$ as indexing simplicial objects.

Form a pullback diagram

\[
\begin{array}{ccc}
N & \to & M^\otimes \\
\downarrow & & \downarrow \\
N(\Delta)^{op} & \overset{\text{L Cut}}{\to} & C^\otimes,
\end{array}
\]

so that $p$ is a locally coCartesian fibration (Lemma 4.2.2.19). Let $u : K \to \Delta \text{LMod}_A(\mathcal{M})$ be a $\theta'$-split simplicial object, corresponding to a map $V : K \times N(\Delta)^{op} \to N$. We observe that every fiber of $p$ is equivalent to $M$, and each of the induced maps $V[n] : K \times \{[n]\} \to N[n]$ can be identified with the composition of $V$ with the forgetful functor $\theta'$. It follows that each of the simplicial objects $V[n]$ is split. Using Lemma 4.7.3.4, we deduce that each $V[n]$ admits a colimit $V[n] : K^\op \to N[n]$, and that these colimits are preserved by each of the associated functors $N[n] : N \to N[n]$ (Remark 4.7.3.4). Applying Proposition 4.4.3.11, we conclude that each $\overline{V}[n]$ is a $p$-colimit diagram. We now invoke Lemma 3.2.2.9 to deduce the existence of a map $\overline{V} : K^\op \times N(\Delta)^{op} \to N$ which induces a $p$-colimit diagram on each fiber $K^\op \times \{[n]\}$. Moreover, Lemma 3.2.2.9 implies that $\overline{V}$ defines a colimit diagram $\overline{\theta} : K^\op \to \text{Map}_{\text{N}(\Delta)^{op}}(N(\Delta)^{op}, N)$. Since $v = \overline{\theta}K$ factors through the full subcategory $\Delta \text{LMod}_A(\mathcal{M}) \subseteq \text{Map}_{\text{N}(\Delta)^{op}}(N(\Delta)^{op}, N)$, it is easy to see that $\overline{\theta}$ factors through $\Delta \text{LMod}_A(\mathcal{M})$. It follows that $\overline{\theta}$ is a colimit of $v$ in $\Delta \text{LMod}_A(\mathcal{M})$. This proves (1), and (2) follows from the observation that $\theta' \circ \overline{\theta} = \overline{V}|K^\op \times \{[0]\}$ is a colimit diagram in $M$ by construction.

The difficult part of Theorem 4.7.4.5 is the proof that (c) implies (a). Assume that $G : \mathcal{D} \to \mathcal{C}$ is a functor which admits a left adjoint and therefore an endomorphism monad $T$, and let $G' : \mathcal{D} \to \text{LMod}_T(\mathcal{C})$ be the induced functor. Note that $G'$ is an equivalence of $\infty$-categories if and only if it is conservative and admits a fully faithful left adjoint. The first condition is immediate if $G$ is conservative (since $G$ is the composition of $G'$ with the forgetful functor $\text{LMod}_T(\mathcal{C}) \to \mathcal{C}$). Consequently, to complete the proof of Theorem 4.7.4.5 it will suffice to verify the following:

**Lemma 4.7.4.13.** Let $G : \mathcal{D} \to \mathcal{C}$ be a functor between $\infty$-categories which admits a left adjoint $F$ and let $T$ be an endomorphism monad for $G$. Assume that:

1. Every $G$-split simplicial object of $\mathcal{D}$ admits a colimit in $\mathcal{D}$, and this colimit is preserved by $G$. 

...
Then the canonical map \( G' : \mathcal{D} \to \text{LMod}_T(\mathcal{C}) \) admits a fully faithful left adjoint.

**Proof.** Let \( \mathcal{X} \subseteq \text{LMod}_T(\mathcal{C}) \) be the full subcategory spanned by those left \( T \)-modules \( M \in \text{LMod}_T(\mathcal{C}) \) such that the functor

\[
D \mapsto \text{Map}_{\text{LMod}_T(\mathcal{C})}(M, G'(D)) \in S
\]

is corepresentable by an object \( F'(M) \in \mathcal{D} \). In this case, \( F'(M) \) is well-defined up to canonical equivalence and the construction \( M \mapsto F'(M) \) determines a functor \( F' : \mathcal{X} \to \mathcal{D} \), which we can regard as a partially-defined left adjoint to \( G' \). Let \( G'' : \text{LMod}_T(\mathcal{C}) \to \mathcal{C} \) be the forgetful functor, and let \( F'' : \mathcal{C} \to \text{LMod}_T(\mathcal{C}) \) be a left adjoint to \( G'' \), given informally by \( C \mapsto T(C) \). Let \( \mathcal{X}_0 \) denote the full subcategory of \( \mathcal{X} \) spanned by those objects \( M \) such that the unit map \( u_M : G''(M) \to (G''G'F')(M) \cong GF'(M) \) is an equivalence in \( \mathcal{C} \). For every object \( C \in \mathcal{C} \), the object \( F''(C) \) belongs to \( \mathcal{X} \) and we have a canonical equivalence \( F'(C) \cong F''(F''(C)) \).

Moreover, \( u_{F''(C)} \) can be identified with the canonical map

\[
T(C) \cong G''F''(C) \to G''G'F''(C) \cong GF(C)
\]

which is an equivalence by virtue of our assumption that \( T \) is an endomorphism monad for \( G \). It follows that \( \mathcal{X}_0 \) contains the essential image of \( F'' \). Let \( M \) be an arbitrary object of \( \text{LMod}_T(\mathcal{C}) \), and let \( M_\bullet \) denote the simplicial object of \( \text{LMod}_T(\mathcal{C}) \) given by the bar construction \( \text{Bar}_T(T, M)_\bullet \). Then \( M \cong |M_\bullet| \) and \( M_\bullet \) is a \( G'' \)-split by Example 4.7.3.7. Each \( M_n \) belongs to the essential image of \( F'' \) and therefore to \( \mathcal{X}_0 \), so that \( G(F'(M_\bullet)) \cong G''(M_\bullet) \) is a split simplicial object of \( \mathcal{C} \) and therefore \( F'(M_\bullet) \) is a \( G \)-split simplicial object of \( \mathcal{D} \). It follows from assumption (2) that \( F'(M_\bullet) \) admits a colimit \( D \in \mathcal{D} \), so that \( M \in \mathcal{X} \) and \( F'(M) \cong D \).

The map \( u_M \) is given by the composition

\[
G''(M) \cong |G''(M_\bullet)| \cong |G(F'(M_\bullet))| \to G|F'(M_\bullet)| \cong GF'(M)
\]

and is therefore an equivalence, since \( G \) preserves colimits of \( G \)-split simplicial objects. It follows that \( \mathcal{X}_0 = \text{LMod}_T(\mathcal{C}) \). In other words, the functor \( G' : \mathcal{D} \to \text{LMod}_T(\mathcal{C}) \) admits a left adjoint \( F' \), and the unit map \( \text{id} \to G' \circ F' \) induces an equivalence of functors \( u : G'' \to G'' \circ G' \circ F' \). Since the functor \( G'' \) is conservative (Corollary 4.2.3.2), we conclude that \( G'' \circ F' \cong \text{id}_{\text{LMod}_T(\mathcal{C})} \), so that \( F' \) is fully faithful.

For later use, we record another consequence of the proof of Lemma 4.7.4.13:

**Proposition 4.7.4.14.** Let \( \mathcal{C} \xrightarrow{F} \mathcal{D} \) be a pair of adjoint functors between \( \infty \)-categories which satisfies conditions (1) and (2) of Theorem 4.7.4.5. For every object \( D \in \mathcal{D} \), there exists a \( G \)-split simplicial object \( D_\bullet : N(\Delta)^{op} \to \mathcal{D} \) having colimit \( D \), such that each \( D_n \) lies in the essential image of \( F \).

**Remark 4.7.4.15.** In the situation of Proposition 4.7.4.14, the simplicial object \( D_\bullet \) can be chosen to depend functorially on \( D \), and for each \( n \) we can choose an object \( C \in \mathcal{C} \) and an identification \( D_n \cong F(C) \) which depends functorially on \( D \). This follows either from the proof of Lemma 4.7.4.13, or from applying Proposition 4.7.4.14 to the induced adjunction

\[
\text{Fun}(\mathcal{D}, \mathcal{C}) \xrightarrow{F'} \text{Fun}(\mathcal{D}, \mathcal{D}).
\]

We now describe a few applications of Proposition 4.7.4.14 (and Remark 4.7.4.15):

**Corollary 4.7.4.16.** Suppose we are given a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{U} & \mathcal{C}' \\
\downarrow{G} & & \downarrow{G'} \\
\mathcal{D} & \xrightarrow{F'} & \mathcal{D}'
\end{array}
\]

Assume that:
4.7. MONADS AND THE BARR-BECK THEOREM

(1) The functors $G$ and $G'$ admit left adjoints $F$ and $F'$.

(2) Every $G$-split simplicial object of $\mathcal{C}$ admits a colimit in $\mathcal{C}$, which is preserved by $G$.

(3) Every $G'$-split simplicial object of $\mathcal{C}'$ admits a colimit in $\mathcal{C}'$, which is preserved by $G'$.

(4) The functor $G'$ is conservative.

(5) For each object $D \in \mathcal{D}$, the unit map unit map $D \rightarrow GF(D) \simeq G'(UF(D))$ induces an equivalence

$$\alpha_D : F'(D) \rightarrow UF(D) \text{ in } \mathcal{C}'$$

Then $U$ admits a fully faithful left adjoint. Moreover, $U$ is an equivalence of $\infty$-categories if and only if $G$ is conservative.

Remark 4.7.4.17. In the situation of Corollary 4.7.4.16, we can replace (5) by the following apparently weaker condition: for each $D \in \mathcal{D}$, the morphism $G'((\alpha_D) : G'F'(D) \rightarrow GF(D)$ is an equivalence in $\mathcal{D}$ (since the functor $G'$ is conservative).

Proof. We begin by constructing a left adjoint $T$ to the functor $U$. Let $j' : \mathcal{C}' \rightarrow \text{Fun}(\mathcal{C}', \mathcal{S})$ be the Yoneda embedding, and let $T_0$ denote the composition $\mathcal{C}' \rightarrow \text{Fun}(\mathcal{C}', \mathcal{S}) \rightarrow \text{Fun}(\mathcal{C}, \mathcal{S})$. Let $\text{Fun}_0(\mathcal{C}, \mathcal{S})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{S})$ spanned by the corepresentable functors (that is, the essential image of the Yoneda embedding $j : \mathcal{C}' \rightarrow \text{Fun}(\mathcal{C}, \mathcal{S})$). To prove the existence of $T$, it will suffice to show that the essential image of $T_0$ is contained in $\text{Fun}_0(\mathcal{C}, \mathcal{S})$; we can then write $T$ as the composition $j^{-1} \circ T_0$, where $j^{-1}$ is a homotopy inverse to $j : \mathcal{C}' \rightarrow \text{Fun}_0(\mathcal{C}, \mathcal{S})$.

Fix an object $C' \in \mathcal{C}'$; we wish to show that $T_0(C') \in \text{Fun}_0(\mathcal{C}, \mathcal{S})$. Using Proposition 4.7.4.14, we can write $\mathcal{C}'$ as the geometric realization of a $G'$-split simplicial object $C'_\bullet$, such that each $C'_n \simeq F'(D_n)$ for some $D_n \in \mathcal{D}$. It follows that $T_0(C') \in \text{Fun}_0(\mathcal{C}, \mathcal{S})$ is the limit of of the cosimplicial object $T_0(C'_\bullet)$. Each of the functors $T_0(C'_n)$ is corepresentable by the object $F(D_n')$, and therefore belongs to $\text{Fun}_0(\mathcal{C}, \mathcal{S})$. It follows that we can write $T_0(C'_n) = j(C_n)$ for some simplicial object $C_\bullet$ in $\mathcal{C}$. By construction, there is an evident map $\alpha : C'_n \rightarrow UF(C_n)$. Condition (5) implies that $G'((\alpha))$ is an equivalence $G'(C'_\bullet) \rightarrow (G' \circ U)(C_\bullet) \simeq G(C_\bullet)$, so that $C'_n$ is $G$-split. It follows that $C_\bullet$ admits a colimit $C \in \mathcal{C}$, so that

$$T_0(C') \simeq \lim T_0(C'_n) \simeq \lim j(C_n) \simeq j(C)$$

is representable by $C$. This completes the proof of the existence of $T$.

We now prove that $T$ is fully faithful. This is equivalent to showing that the unit map

$$u : \text{id}_{\mathcal{C}'} \rightarrow U \circ T$$

induces an equivalence $C' \rightarrow (U \circ T)(C')$ for each object $C' \in \mathcal{C}$. Let $C'_n$ and $C_n$ be as above. We wish to prove that the canonical equivalence $C'_n \simeq UF(C_n)$ induces an equivalence

$$C' \simeq \lim C'_n \simeq \lim UF(C_n) \rightarrow U(\lim C_n).$$

In other words, we wish to prove that $U$ preserves the colimit of the simplicial object $C_\bullet$. Since $G'$ is conservative, it will suffice to show that $G = G' \circ U$ preserves the colimit of the simplicial object $C_\bullet$. This follows from our hypothesis on $G$, since $C_\bullet$ is $G$-split.

We conclude by observing that if $U$ is an equivalence, then $G \simeq G' \circ U$ is conservative by virtue of (4). Conversely, if $G$ is conservative, then $U$ is conservative and therefore (since it admits a fully faithful left adjoint) is an equivalence of $\infty$-categories.

Our next result makes use of the notation and terminology of §T.5.5.8.

Corollary 4.7.4.18. Suppose given a pair of adjoint functors between $\infty$-categories $\mathcal{C} \xrightarrow{F} \mathcal{D}$. Assume that:
(i) The $\infty$-category $D$ admits filtered colimits and geometric realizations, and $G$ preserves filtered colimits and geometric realizations.

(ii) The $\infty$-category $\mathcal{C}$ is projectively generated (Definition T.5.5.8.23).

(iii) The functor $G$ is conservative.

Then:

(1) The $\infty$-category $D$ is projectively generated.

(2) An object $D \in D$ is compact and projective if and only if there exists a compact projective object $C \in \mathcal{C}$ such that $D$ is a retract of $F(C)$.

(3) The functor $G$ preserves all sifted colimits.

Proof. Let $\mathcal{C}^0$ denote the full subcategory of $\mathcal{C}$ spanned by the compact projective objects. Let $D^0$ denote the essential image of $F|\mathcal{C}^0$. Using assumption (i), we deduce that $D^0$ consists of compact projective objects of $D$. Without loss of generality, we may assume that the $\infty$-category $D$ is minimal, so that $D^0$ is small. Moreover, since $\mathcal{C}^0$ is stable under finite coproducts in $\mathcal{C}$, and $F$ preserves finite coproducts, we conclude that $D^0$ admits finite coproducts (which are also finite coproducts in $D$).

Let $D' = \mathcal{P}_\Sigma(D^0)$ (see Definition T.5.5.8.8). Using Proposition T.5.5.8.15, we deduce that the inclusion $D^0 \subseteq D$ is homotopic to a composition

$$D^0 \xrightarrow{f} D' \xrightarrow{f'} D,$$

where the functor $f$ preserves filtered colimits and geometric realizations. Combining Proposition T.5.5.8.22 with Proposition 4.7.4.14 and assumption (ii), we conclude that $f$ is an equivalence of $\infty$-categories. This proves (1). Moreover, the proof shows that $D^0$ is spanned by a set of compact projective generators for $D$ (Definition T.5.5.8.23), so that assertion (2) follows from Proposition T.5.5.8.25. Assertion (3) now follows from Proposition T.5.5.8.15.

We also have the following variant of Corollary 3.2.3.3:

Corollary 4.7.4.19. Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads. Assume that $\mathcal{O}^\otimes$ is unital and that there exists an uncountable regular cardinal $\kappa$ with the following properties:

(1) The $\infty$-operad $\mathcal{O}^\otimes$ is essentially $\kappa$-small.

(2) For each object $X \in \mathcal{O}$, the $\infty$-category $\mathcal{C}_X$ admits $K$-indexed colimits for every weakly contractible $\kappa$-small simplicial set $K$.

(3) For every collection of objects $X_1, \ldots, X_n, Y \in \mathcal{O}$ and every operation $\alpha \in \text{Mul}_{\mathcal{O}}(\{X_i\}, Y)$, the associated functor

$$\prod_{1 \leq i \leq n} \mathcal{C}_{X_i} \to \mathcal{C}_Y$$

preserves $K$-indexed colimits separately in each variable for every weakly contractible $\kappa$-small simplicial set $K$.

Then for every $\kappa$-small weakly contractible simplicial set $K$, the $\infty$-category $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$ admits $K$-indexed colimits.

Proof. Let $K$ be a $\kappa$-small weakly contractible simplicial set and suppose we are given a diagram $\{A_\alpha\}_{\alpha \in K}$ in the $\infty$-category $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$; we wish to prove that this diagram admits a colimit in $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$. Let $\mathcal{O}^\otimes_0 = \mathcal{O}^\otimes \times_{\text{Comm}^\otimes} \mathcal{E}_0^\otimes$ be as in Corollary 3.1.3.7, so that the forgetful functor

$$G : \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{\mathcal{O}_0}(\mathcal{C})$$
admits a left adjoint $F$ (Corollary 3.1.3.7). It follows from Example 4.7.4.11 that $G$ exhibits $\text{Alg}_{/\emptyset}(\mathcal{C})$ as monadic over $\text{Alg}_{\alpha_n/\emptyset}(\mathcal{C})$. Using Proposition 4.7.4.14 and Remark 4.7.4.15, we can assume that each $\alpha_n$ is given as the geometric realization of a simplicial object $A_n$ (depending functorially on $\alpha$) and that for each $n$ we have an identification $A_{\alpha_n} \simeq F(B_{\alpha_n})$ (also depending functorially on $\alpha$). Since $\text{Alg}_{/\emptyset}(\mathcal{C})$ admits geometric realizations of simplicial objects (Proposition 3.2.3.1), it will suffice to show that each of the diagrams $\{A_{\alpha_n}\}_{\alpha \in K}$ admits a colimit in $\text{Alg}_{/\emptyset}(\mathcal{C})$. The functor $F$ preserves colimits (since it is a left adjoint), so we are reduced to proving that the diagram $\{B_{\alpha_n}\}_{\alpha \in K}$ admits a colimit in $\text{Alg}_{\alpha_n/\emptyset}(\mathcal{C})$. This follows from Proposition 3.2.3.8.

**Example 4.7.4.20.** Let $\mathcal{C}^{\otimes}$ be a monoidal $\infty$-category. Assume that for every countable weakly contractible simplicial set $K$, the $\infty$-category $\mathcal{C}$ admits $K$-indexed colimits and the tensor product

$$\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$$

preserves $K$-indexed colimits separately in each variable. Then for every countable weakly contractible simplicial set $K$, the $\infty$-category $\text{Alg}(\mathcal{C})$ admits $K$-indexed colimits.

**Remark 4.7.4.21.** In the situation of Corollary 4.7.4.19, suppose that we are given a $\emptyset$-monoidal functor $T : \mathcal{C}^{\otimes} \to \mathcal{D}^{\otimes}$, where $r : \mathcal{D}^{\otimes} \to \emptyset^{\otimes}$ is a coCartesian fibration of $\infty$-operads which also satisfies hypotheses (2) and (3). Suppose further that for each object $X \in \emptyset$, the induced map $\mathcal{C}_X \to \mathcal{D}_X$ preserves colimits indexed by $\kappa$-small weakly contractible simplicial sets. Then the induced map $\text{Alg}_{/\emptyset}(\mathcal{C}) \to \text{Alg}_{/\emptyset}(\mathcal{D})$ preserves colimits indexed by $\kappa$-small weakly contractible simplicial sets. This follows from the proof of Corollary 4.7.4.19 (together with Remark 3.1.3.8).

For later use, we record the following the following consequence of the Barr-Beck theorem:

**Proposition 4.7.4.22.** Suppose given a commutative diagram of $\infty$-categories

$$\begin{array}{ccc}
\mathcal{D} & \xrightarrow{G'} & \mathcal{E} \\
\downarrow & & \downarrow G \\
\mathcal{C} & \xrightarrow{G''} & \mathcal{D}.
\end{array}$$

Suppose that $G$ exhibits $\mathcal{E}$ as monadic over $\mathcal{C}$, that $G''$ is conservative, and that $G'$ admits a left adjoint. Then $G'$ exhibits $\mathcal{E}$ as monadic over $\mathcal{D}$.

**Warning 4.7.4.23.** Monadicity is not transitive: in the situation of Proposition 4.7.4.22, if $G''$ exhibits $\mathcal{D}$ as monadic over $\mathcal{C}$ and $G'$ exhibits $\mathcal{E}$ as monadic over $\mathcal{D}$, then $G$ need not exhibit $\mathcal{E}$ as monadic over $\mathcal{C}$.

**Proof.** We will show that the functor $G'$ satisfies the hypotheses of Theorem 4.7.4.5:

1. The functor $G'$ is conservative. For suppose that $\alpha : E \to E'$ is a morphism in $\mathcal{E}$ such that $G'(\alpha)$ is an equivalence. Then $G(\alpha)$ is an equivalence. Since $G$ is conservative (by Theorem 4.7.4.5), we deduce that $\alpha$ is an equivalence.

2. Let $E_\bullet$ be a simplicial object of $\mathcal{E}$, and suppose that $G'E_\bullet$ is a split simplicial object of $\mathcal{D}$. Then $GE_\bullet = G''G'E_\bullet$ is a split simplicial object of $\mathcal{C}$. Since $G$ exhibits $\mathcal{E}$ as monadic over $\mathcal{C}$, Theorem 4.7.4.5 implies that $E_\bullet$ admits a colimit $|E_\bullet|$ in $\mathcal{E}$, and that the canonical map $\alpha : |GE_\bullet| \to G|E_\bullet|$ is an equivalence in $\mathcal{C}$. We wish to show that $\beta : |GE_\bullet| \to G''|E_\bullet|$ is an equivalence in $\mathcal{D}$. Since $G''$ is conservative, it will suffice to show that $G''(\beta)$ is an equivalence in $\mathcal{C}$. Using the commutative diagram

$$\begin{array}{ccc}
\gamma & \xrightarrow{G''(\beta)} & G''|E_\bullet| \\
\downarrow & & \downarrow \alpha \\
|GE_\bullet| & \xrightarrow{\alpha} & G|E_\bullet|,
\end{array}$$

we are reduced to proving that $\gamma$ is an equivalence. In other words, we must show that $G''$ preserves the colimit of the split simplicial object $G'E_\bullet$, which follows from Remark 4.7.3.4.
Remark 4.7.5.3. Fix a simplicial set \( \mathcal{E} \to \mathcal{D} \). We will say that an object (fibration, \( E \to \mathcal{E} \)) are adjoint if there exists a correspondence \( F : \mathcal{E} \to \mathcal{D} \) and a Cartesian fibration associated to \( G : \mathcal{D} \to \mathcal{E} \) (see §T.3.1.3.7, whose fibrant objects are pairs \((S, M)\) where \( M \) contains all degenerate edges. The category \((\Set^+_\Delta)_S\) can be endowed with the Cartesian model structure of Proposition T.3.1.3.7, whose fibrant objects are those pairs \((f : X \to S, M)\) where \( f \) is a Cartesian fibration and \( M \) is the collection of \( f \)-Cartesian edges of \( X \). Similarly, \((\Set^+_\Delta)_S\) can be endowed with the coCartesian model structure of Remark T.3.1.3.9, whose fibrant objects are pairs \((f : X \to S, M)\) where \( f \) is a coCartesian fibration and \( M \) is the collection of \( f \)-coCartesian edges of \( X \). We now introduce a variant on these model structures, which is adapted to a discussion of biCartesian fibrations.

Definition 4.7.5.1. We will say that a map of simplicial sets \( q : X \to S \) is a biCartesian fibration if it is both a Cartesian fibration and a coCartesian fibration.

Fix a simplicial set \( S \). We let \((\Set^+_\Delta)_S\) denote the category of marked simplicial sets over \( S \) (see §T.3.1). An object of \((\Set^+_\Delta)_S\) is given by a pair \((f : X \to S, M)\), where \( f \) is a map of simplicial sets and \( M \) is a collection of edges in \( X \) which contains all degenerate edges. The category \((\Set^+_\Delta)_S\) can be endowed with the Cartesian model structure of Proposition T.3.1.3.7, whose fibrant objects are those pairs \((f : X \to S, M)\) where \( f \) is a Cartesian fibration and \( M \) is the collection of \( f \)-Cartesian edges of \( X \). Similarly, \((\Set^+_\Delta)_S\) can be endowed with the coCartesian model structure of Remark T.3.1.3.9, whose fibrant objects are pairs \((f : X \to S, M)\) where \( f \) is a coCartesian fibration and \( M \) is the collection of \( f \)-coCartesian edges of \( X \). We now introduce a variant on these model structures, which is adapted to a discussion of biCartesian fibrations.

Definition 4.7.5.2. Let \( S \) be a simplicial set. We define a category \((\Set^+_\Delta^+)_S\) as follows:

(a) The objects of \((\Set^+_\Delta^+)_S\) are triples \((X, E, E')\) where \( X \) is a simplicial set equipped with a map \( X \to S \) and \( E, E' \subseteq \text{Hom}_{\Set_\Delta^+}(\Delta^1, X) \) are sets of edges which contain all degenerate edges of \( X \).

(b) Given a pair of objects \((X, E, E'), (Y, F, F') \in (\Set^+_\Delta^+)_S\), a morphism from \((X, E, E')\) to \((Y, F, F')\) is a map of simplicial sets \( f : X \to Y \) such that \( f(E) \subseteq F, f(E') \subseteq F' \), and the diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
S & \end{array}
\]

is commutative.

We will say that an object \((X, E, E') \in (\Set^+_\Delta^+)_S\) is \( S \)-bifibered if the map \( p : X \to S \) is a biCartesian fibration, \( E \) is the collection of \( p \)-Cartesian edges of \( X \), and \( E' \) is the collection of \( p \)-coCartesian edges of \( X \).

Remark 4.7.5.3. Fix a simplicial set \( S \). For every object \((X, E, E') \in (\Set^+_\Delta^+)_S\) and every simplicial set \( K \), we define a new object \( K \otimes (X, E, E') \in (\Set^+_\Delta^+)_S \) by the formula

\[
K \otimes (X, E, E') = (K \times X, \phi^{-1}(E), \phi^{-1}(E'))
\]
where \( \phi : K \times X \to X \) denotes the projection onto the second factor. Via this construction, we can regard \( (\operatorname{Set}^+ \downarrow)_S \) as enriched, tensored, and cotensored over the category of simplicial sets. In particular, for every pair of objects \( X = (X,E,E') \), \( Y = (Y,F,F') \in (\operatorname{Set}^+ \downarrow)_S \), we have a mapping space \( \operatorname{Map}(\operatorname{Set}^+ \downarrow)_S(X,Y) \subseteq \operatorname{Fun}_S(X,Y) \).

**Remark 4.7.5.4.** Fix a simplicial set \( S \). Suppose we are given a morphism \( \alpha : \overline{X} = (X,E,E') \to (Y,F,F') = \overline{Y} \) in \((\operatorname{Set}^+ \downarrow)_S\), and that \( \overline{Z} = (Z,G,G') \in (\operatorname{Set}^+ \downarrow)_S \) is \( S \)-bifibered. Then \( \alpha \) induces a categorical fibration of \( \infty \)-categories \( \operatorname{Fun}_S(Y,Z) \to \operatorname{Fun}_S(X,Z) \). The simplicial sets \( \operatorname{Map}(\operatorname{Set}^+ \downarrow)_S(\overline{X},\overline{Z}) \) can be described as the subcategory of \( \operatorname{Fun}_S(X,Z) \) whose objects are maps \( f : X \to Y \) such that \( f(E) \subseteq G \) and \( f(E') \subseteq G' \), and whose morphisms are equivalences. The simplicial set \( \operatorname{Map}(\operatorname{Set}^+ \downarrow)_S(\overline{Y},\overline{Z}) \) has an analogous description as a subcategory of \( \operatorname{Fun}_S(Y,Z) \). It follows that composition with \( \alpha \) induces a Kan fibration of Kan complexes

\[
\operatorname{Map}(\operatorname{Set}^+ \downarrow)_S(\overline{Y},\overline{Z}) \to \operatorname{Map}(\operatorname{Set}^+ \downarrow)_S(\overline{X},\overline{Z}).
\]

**Definition 4.7.5.5.** Let \( S \) be a simplicial set and let \( f : \overline{X} \to \overline{Y} \) be a morphism in \((\operatorname{Set}^+ \downarrow)_S\). We will say that \( f \) is a biCartesian equivalence if, for every \( S \)-bifibered object \( \overline{Z} \in (\operatorname{Set}^+ \downarrow)_S \), composition with \( f \) induces a homotopy equivalence of Kan complexes

\[
\operatorname{Map}(\operatorname{Set}^+ \downarrow)_S(\overline{Y},\overline{Z}) \to \operatorname{Map}(\operatorname{Set}^+ \downarrow)_S(\overline{X},\overline{Z}).
\]

**Example 4.7.5.6.** Let \( f : (X,E,E') \to (Y,F,F') \) be a morphism between \( S \)-bifibered objects of \((\operatorname{Set}^+ \downarrow)_S\). Then \( f \) is a biCartesian equivalence if and only if it admits a homotopy inverse in the simplicial category \((\operatorname{Set}^+ \downarrow)_S\). Using Proposition T.3.1.3.5, we see that this is equivalent to the requirement that for each vertex \( s \in S \), the induced map \( f_s : X_s \to Y_s \) is an equivalence of \( \infty \)-categories.

**Remark 4.7.5.7.** Fix a simplicial set \( S \), and let \((\operatorname{Set}^+ \downarrow)_S\) denote the category of marked simplicial sets over \( S \). There are evident forgetful functors \((\operatorname{Set}^+ \downarrow)_S \xrightarrow{L} (\operatorname{Set}^+ \downarrow)_S \xrightarrow{E} (\operatorname{Set}^+ \downarrow)_S\), given by the formulas

\[
\pi(X,E,E') = (X,E) \quad \pi'(X,E,E') = (X,E').
\]

Note that \( \overline{X} = (X,E,E') \) is \( S \)-bifibered if and only if \( \pi(\overline{X}) \) is fibrant with respect to the Cartesian model structure on \((\operatorname{Set}^+ \downarrow)_S\) and \( \pi'(\overline{X}) \) is fibrant with respect to the coCartesian model structure on \((\operatorname{Set}^+ \downarrow)_S\).

The functors \( \pi \) and \( \pi' \) admit left adjoints \( \pi^* \), \( \pi'^* : (\operatorname{Set}^+ \downarrow)_S \to (\operatorname{Set}^+ \downarrow)_S \), given by the formulas

\[
\pi^*(X,E) = (X,E,E_0) \quad \pi'^*(X,E) = (X,E_0,E)
\]

where \( E_0 \) denotes the collection of all degenerate edges in \( X \). It follows immediately from the definitions that \( \pi^* \) carries Cartesian equivalences in \((\operatorname{Set}^+ \downarrow)_S\) to biCartesian equivalences in \((\operatorname{Set}^+ \downarrow)_S\), and that \( \pi'^* \) carries coCartesian equivalences in \((\operatorname{Set}^+ \downarrow)_S\) to biCartesian equivalences in \((\operatorname{Set}^+ \downarrow)_S\).

Note that an an object \( \overline{X} \in (\operatorname{Set}^+ \downarrow)_S \) is \( S \)-bifibered if and only if, for every marked anodyne morphism \( \alpha : \overline{Y} \to \overline{Z} \) in \((\operatorname{Set}^+ \downarrow)_S\), \( \overline{X} \) has the extension property with respect to \( \pi^*(\alpha) \) and \( \pi'^*(\alpha^\text{op}) \). Arguing as in the proof of Proposition T.3.1.3.7, we deduce the following:

**Lemma 4.7.5.8.** Let \( S \) be a simplicial set. There exists a functor \( T : (\operatorname{Set}^+ \downarrow)_S \to (\operatorname{Set}^+ \downarrow)_S \) and a natural transformation \( u : \text{id} \to T \) with the following properties:

1. For every object \( \overline{X} \in (\operatorname{Set}^+ \downarrow)_S \), the object \( T\overline{X} \) is \( S \)-bifibered.

2. For every object \( \overline{X} \in (\operatorname{Set}^+ \downarrow)_S \), the natural transformation \( u \) induces a biCartesian equivalence \( \overline{X} \to T\overline{X} \).
The functor $T$ commutes with filtered colimits.

If $T$ is the functor of Lemma 4.7.5.8, then a map $\alpha : X \to Y$ is a biCartesian equivalence if and only if the induced map $T(\alpha) : TX \to TY$ is a biCartesian equivalence. By Example 4.7.5.6, this is equivalent to the requirement that $T(\alpha)$ induces a categorical equivalence after passing to the fiber over each vertex $s \in S$. Since the collection of categorical equivalences in $\text{Set}_{\Delta}$ is perfect (in the sense of Definition T.A.2.6.10), Corollary T.A.2.6.12 guarantees the following:

**Lemma 4.7.5.9.** Let $S$ be a simplicial set. The collection of biCartesian equivalences in $(\text{Set}_{\Delta}^{+})_{/S}$ is perfect (in particular, it is stable under filtered colimits).

**Theorem 4.7.5.10.** Let $S$ be a simplicial set. There exists a combinatorial left proper model structure on the category $(\text{Set}_{\Delta}^{+})_{/S}$, which can be characterized as follows:

1. A morphism $\alpha : (X, E, E') \to (Y, F, F')$ in $(\text{Set}_{\Delta}^{+})_{/S}$ is a cofibration if and only if the underlying map of simplicial sets $X \to Y$ is a monomorphism.

2. A morphism $\alpha : (X, E, E') \to (Y, F, F')$ in $(\text{Set}_{\Delta}^{+})_{/S}$ is a weak equivalence if and only if it is a biCartesian equivalence.

3. A morphism $\alpha : (X, E, E') \to (Y, F, F')$ in $(\text{Set}_{\Delta}^{+})_{/S}$ is a fibration if and only if it has the right lifting property with respect to every morphism $\beta$ which is both a cofibration and a weak equivalence.

We will refer to the model structure of Theorem 4.7.5.10 as the biCartesian model structure on $(\text{Set}_{\Delta}^{+})_{/S}$.

**Proof.** It will suffice to show that the hypotheses of Proposition T.A.2.6.13 are satisfied:

1. The collection of biCartesian equivalences is perfect (Lemma 4.7.5.9).

2. The collection of biCartesian equivalences is closed under pushouts by cofibrations. This follows from Remark 4.7.5.4, together with the right properness of the usual model structure on the category of simplicial sets.

3. Let $\alpha : (X, E, E') \to (Y, F, F')$ be a morphism which has the right lifting property with respect to every cofibration. Then the underlying map $X \to Y$ is a trivial Kan fibration of simplicial sets, and we have $E = \alpha^{-1}F$ and $E' = \alpha^{-1}F'$. It follows that $\alpha$ admits a section $\beta$, and the composition $\beta \circ \alpha$ is (fiberwise) homotopic to the identity map form $(X, E, E')$ to itself; in particular, $\alpha$ is a biCartesian equivalence.

**Remark 4.7.5.11.** For every simplicial set $S$, the biCartesian model structure on $(\text{Set}_{\Delta}^{+})_{/S}$ is compatible with the simplicial structure of Remark 4.7.5.3.

**Remark 4.7.5.12.** Let $S$ be a simplicial set. Let us regard $(\text{Set}_{\Delta}^{+})_{/S}$ as endowed with the Cartesian model structure of §T.3.1.3, and let $(\text{Set}_{\Delta}^{+})_{/S'}$ denote the same category $(\text{Set}_{\Delta}^{+})_{/S}$ endowed with the coCartesian model structure. The functors $(\text{Set}_{\Delta}^{+})_{/S} \xrightarrow{\leftarrow} (\text{Set}_{\Delta}^{+})_{/S'} \xrightarrow{\leftarrow} (\text{Set}_{\Delta}^{+})_{/S'}$ of Remark 4.7.5.7 are simplicial right Quillen functors, and induce limit-preserving functors between the underlying $\infty$-categories

$$N((\text{Set}_{\Delta}^{+})_{/S}) \leftrightarrow N((\text{Set}_{\Delta}^{+})_{/S'}) \rightarrow N((\text{Set}_{\Delta}^{+})_{/S'}).$$

These functors allow us to identify $N((\text{Set}_{\Delta}^{+})_{/S'})$ with a subcategory of either $N((\text{Set}_{\Delta}^{+})_{/S})$ or $N((\text{Set}_{\Delta}^{+})_{/S'})$.

Our next goal is to identify the image of $N((\text{Set}_{\Delta}^{+})_{/S})$ under these equivalences. We begin by recalling a few definitions.
Definition 4.7.5.13. Suppose we are given a diagram of ∞-categories \( \sigma : \)
\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{G} & \mathcal{D} \\
\downarrow U & & \downarrow V \\
\mathcal{C}' & \xrightarrow{G'} & \mathcal{D}'
\end{array}
\]
which commutes up to a specified equivalence \( \alpha : V \circ G \simeq G' \circ U \). We say that this diagram \( \sigma \) is left adjointable if the functors \( G \) and \( G' \) admit left adjoints \( F \) and \( F' \), respectively, and if the composite transformation
\[
F' \circ V \to F' \circ V \circ G \circ F' \simeq F' \circ G' \circ U \circ F \to U \circ F
\]
is an equivalence. We say that \( \sigma \) is right adjointable if the functors \( G \) and \( G' \) admit right adjoints \( H \) and \( H' \), and the composite transformation
\[
U \circ H \to H' \circ G' \circ U \circ H \xrightarrow{\alpha^{-1}} H' \circ V \circ G \circ H \to H' \circ V
\]
is an equivalence.

Remark 4.7.5.14. Suppose we are given a commutative diagram of ∞-categories \( \sigma : \)
\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{G} & \mathcal{D} \\
\downarrow U & & \downarrow V \\
\mathcal{C}' & \xrightarrow{G'} & \mathcal{D}'
\end{array}
\]
where the functors \( G \) and \( G' \) admit left adjoints, and the functors \( U \) and \( V \) admit right adjoints. Then \( \sigma \) is left adjointable if and only if the transposed diagram
\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{U} & \mathcal{C}' \\
\downarrow G & & \downarrow G' \\
\mathcal{D} & \xrightarrow{V} & \mathcal{D}'
\end{array}
\]
is right adjointable.

Remark 4.7.5.15. In classical category theory, the adjointability of a commutative square of categories is sometimes referred to as the Beck-Chevalley condition.

Definition 4.7.5.16. Let \( S \) be a simplicial set. We define subcategories
\[
\text{Fun}^{\text{LAd}}(S, \mathcal{C}_{\text{at}}^\infty), \text{Fun}^{\text{RAd}}(S, \mathcal{C}_{\text{at}}^\infty) \subseteq \text{Fun}(S, \mathcal{C}_{\text{at}}^\infty)
\]
as follows:

1. Let \( F \in \text{Fun}(S, \mathcal{C}_{\text{at}}^\infty) \). Then \( F \) belongs to \( \text{Fun}^{\text{LAd}}(S, \mathcal{C}_{\text{at}}^\infty) \) ( \( \text{Fun}^{\text{RAd}}(S, \mathcal{C}_{\text{at}}^\infty) \)) if and only if, for every edge \( s \to s' \) in \( S \), the induced functor \( F(s) \to F(s') \) admits a left adjoint (right adjoint).

2. Let \( \alpha : F \to F' \) be a morphism in \( \text{Fun}(S, \mathcal{C}_{\text{at}}^\infty) \), where \( F \) and \( F' \) belong to \( \text{Fun}^{\text{LAd}}(S, \mathcal{C}_{\text{at}}^\infty) \) ( \( \text{Fun}^{\text{RAd}}(S, \mathcal{C}_{\text{at}}^\infty) \)). Then \( \alpha \) is a morphism in \( \text{Fun}^{\text{LAd}}(S, \mathcal{C}_{\text{at}}^\infty) \) ( \( \text{Fun}^{\text{RAd}}(S, \mathcal{C}_{\text{at}}^\infty) \)) if and only if, for every edge \( s \to s' \) in \( S \), the diagram
\[
\begin{array}{ccc}
F(s) & \xrightarrow{F(s)} & F(s') \\
\downarrow & & \downarrow \\
F'(s) & \xrightarrow{F'(s')} & F'(s')
\end{array}
\]
is left adjointable (right adjointable).
The following result is essentially an unwinding of definitions (see Remark T.7.3.1.3):

**Proposition 4.7.5.17.** Let $S$ be a simplicial set.

1. Let $\phi : N((\text{Set}^+_{/S})^o) \hookrightarrow N((\text{Set}^+_{/S})^o)$ be the monomorphism by the right Quillen functor $\pi$ of Remark 4.7.5.12, and let $\psi : N((\text{Set}^+_{/S})^o) \simeq \text{Fun}(\text{op}, \text{Cat}_\infty)$ be the equivalence furnished by Theorem T.3.2.0.1 and Proposition T.4.2.4.4. Then the composition $\psi \circ \phi$ induces an equivalence from $N((\text{Set}^+_{/S})^o)$ onto the subcategory $\text{Fun}^L(\text{op}, \text{Cat}_\infty) \subseteq \text{Fun}(\text{op}, \text{Cat}_\infty)$.

2. Let $\phi' : N((\text{Set}^+_{/S})^o) \hookrightarrow N((\text{Set}^+_{/S})^o)$ be the monomorphism by the right Quillen functor $\pi'$ of Remark 4.7.5.12, and let $\psi' : N((\text{Set}^+_{/S})^o) \simeq \text{Fun}(\text{op}, \text{Cat}_\infty)$ be the equivalence furnished by Theorem T.3.2.0.1 and Proposition T.4.2.4.4. Then the composition $\psi' \circ \phi'$ induces an equivalence from $N((\text{Set}^+_{/S})^o)$ onto the subcategory $\text{Fun}^R(\text{op}, \text{Cat}_\infty) \subseteq \text{Fun}(\text{op}, \text{Cat}_\infty)$.

**Corollary 4.7.5.18.** Let $S$ be a simplicial set. Then:

1. The $\infty$-categories $\text{Fun}^L(\text{op}, \text{Cat}_\infty)$ and $\text{Fun}^R(\text{op}, \text{Cat}_\infty)$ are presentable. In particular, they admit small limits.

2. The inclusions $\text{Fun}^L(\text{op}, \text{Cat}_\infty) \subseteq \text{Fun}(\text{op}, \text{Cat}_\infty)$ and $\text{Fun}^R(\text{op}, \text{Cat}_\infty) \subseteq \text{Fun}(\text{op}, \text{Cat}_\infty)$ admit left adjoints; in particular, they preserve small limits.

3. There is a canonical equivalence of $\infty$-categories

$$\text{Fun}^L(\text{op}, \text{Cat}_\infty) \simeq \text{Fun}^R(\text{op}, \text{Cat}_\infty).$$

We conclude this section by sketching an application of the above ideas, which will be useful. Recall that $\mathcal{P}r^L$ denotes the subcategory of $\mathcal{C}at_\infty$ whose objects are presentable $\infty$-categories and whose morphisms are functors which preserve small colimits, and $\mathcal{P}r^R \subseteq \mathcal{C}at_\infty$ the subcategory whose objects are presentable $\infty$-categories and whose morphisms are accessible functors which preserve small limits. The following result gives a useful criterion for commuting limits and colimits in $\mathcal{P}r^L$ (or $\mathcal{P}r^R$).

**Proposition 4.7.5.19.** Let $S$ and $T$ be simplicial sets, and suppose we are given a diagram $\chi : S \times T \to \mathcal{P}r^L$ with the following properties:

- For every edge $s \to s'$ in $S$ and every edge $t \to t'$ in $T$, the diagram of $\infty$-categories

$$
\begin{array}{ccc}
\chi(s,t) & \longrightarrow & \chi(s',t) \\
\downarrow & & \downarrow \\
\chi(s,t') & \longrightarrow & \chi(s',t')
\end{array}
$$

is right adjointable.

Then there exists a diagram $\overline{\chi} : S^\circ \times T^\circ \to \mathcal{P}r^L$ with the following properties:

- (a) For each $t \in T^\circ$, the map $\overline{\chi}_t : S^\circ \times \{t\} \to \mathcal{P}r^L$ is a colimit diagram.

- (b) For each $s \in S^\circ$, the map $\overline{\chi}_s : \{s\} \times T^\circ \to \mathcal{P}r^L$ is a limit diagram.

- (c) For every edge $s \to s'$ in $S^\circ$ and every edge $t \to t'$ in $T^\circ$, the diagram of $\infty$-categories

$$
\begin{array}{ccc}
\chi(s,t) & \longrightarrow & \chi(s',t) \\
\downarrow & & \downarrow \\
\chi(s,t') & \longrightarrow & \chi(s',t')
\end{array}
$$

is right adjointable.
4.7. MONADS AND THE BARR-BECK THEOREM

More informally: the hypothesis (*) of Proposition 4.7.5.19 guarantee that the canonical map

\[
\lim_{s \in S} \lim_{t \in T} \chi(s, t) \to \lim_{t \in T} \lim_{s \in S} \chi(s, t)
\]

is an equivalence in the \(\infty\)-category \(\mathcal{P}r^L\).

Proof. Let \(\text{Fun}^{\text{RAd}}(S, \widehat{\mathcal{C}at}_\infty)\) be as in Definition 4.7.5.16, but in the setting of \(\infty\)-categories which are not necessarily small. Using assumption (*), we can identify \(\chi\) with a map \(\chi : T \to \text{Fun}^{\text{RAd}}(S, \widehat{\mathcal{C}at}_\infty)\). Let \(\chi' : T \to \text{Fun}^{\text{LAd}}(S^{\text{op}}, \widehat{\mathcal{C}at}_\infty)\) be the composition of \(\chi\) with the equivalence of Corollary 4.7.5.18, and identify \(\chi'\) with a functor \(S^{\text{op}} \times T \to \widehat{\mathcal{C}at}_\infty\).

Let \(s_0\) denote the cone point of \(S^0\), and let \(\tilde{\chi}' : (S^0)^{\text{op}} \times T \to \widehat{\mathcal{C}at}_\infty\) be a right Kan extension of \(\chi'\). We claim that, for every vertex \(s \in S\) and every edge \(t \to t'\) in \(T\), the diagram of \(\infty\)-categories

\[
\begin{array}{ccc}
\tilde{\chi}'(s_0, t) & \to & \tilde{\chi}'(s, t) \\
\downarrow & & \downarrow \\
\tilde{\chi}'(s_0, t') & \to & \tilde{\chi}'(s, t')
\end{array}
\]

is left adjointable. Using Corollary T.5.5.3.4 and Theorem T.5.5.3.18, we conclude that the horizontal functors are morphisms of \(\mathcal{P}r^R\) and therefore admit left adjoints. It will therefore suffice to show that the diagram \(\sigma : \)

\[
\begin{array}{ccc}
\tilde{\chi}'(s_0, t) & \to & \tilde{\chi}'(s_0, t') \\
\downarrow & & \downarrow \\
\tilde{\chi}'(s, t) & \to & \tilde{\chi}'(s, t')
\end{array}
\]

is right adjointable (Remark 4.7.5.14). This follows from Corollary 4.7.5.18, since for every edge \(s \to s'\) in \(S\) the diagram

\[
\begin{array}{ccc}
\chi'(s', t) & \to & \chi'(s', t') \\
\downarrow & & \downarrow \\
\chi'(s, t) & \to & \chi'(s, t')
\end{array}
\]

is right adjointable (by Remark 4.7.5.14).

Let \(\tilde{\chi} : (S^0)^{\text{op}} \times T^a \to \widehat{\mathcal{C}at}_\infty\) be a right Kan extension of \(\tilde{\chi}'\). It follows from Corollary 4.7.5.18 that, for every edge \(s \to s'\) in \(S^0\) and every edge \(t \to t'\) in \(T^a\), the diagram

\[
\begin{array}{ccc}
\tilde{\chi}'(s', t) & \to & \tilde{\chi}'(s, t) \\
\downarrow & & \downarrow \\
\tilde{\chi}'(s', t') & \to & \tilde{\chi}'(s, t')
\end{array}
\]

is left adjointable. Consequently, we may identify \(\tilde{\chi}'\) with a map \(T^a \to \text{Fun}^{\text{LAd}}((S^0)^{\text{op}}, \widehat{\mathcal{C}at}_\infty)\). Let \(\overline{\chi} : T^a \to \text{Fun}^{\text{RAd}}(S^0, \widehat{\mathcal{C}at}_\infty)\) be the composition of \(\tilde{\chi}'\) with the equivalence of Corollary 4.7.5.18. We will identify \(\overline{\chi}\) with a functor \(S^0 \times T^a \to \widehat{\mathcal{C}at}_\infty\). The restriction \(\overline{\chi}(S \times T)\) is equivalent to \(\chi\); replacing \(\overline{\chi}\) by an equivalent diagram if necessary, we may assume that \(\overline{\chi}\) is an extension of \(\chi\). By construction, the functor \(\overline{\chi}\) satisfies (c).

We next claim that the diagram \(\overline{\chi}\) takes values in \(\mathcal{P}r^L \subseteq \widehat{\mathcal{C}at}_\infty\). To prove this, we first show that for every vertex \((s, t) \in S^0 \times T^a\), the \(\infty\)-category \(\overline{\chi}(s, t) \simeq \overline{\chi}'(s, t)\) is presentable. If \((s, t) \in S \times T\), then the result is
obvious. If \( s = s_0 \) and \( t \in T \), then \( \chi(s, t) \simeq \lim_{\to} \chi^\prime_i \) is presentable by Theorem T.5.5.3.18. If \( s \in S \) and \( t \) is the cone point of \( T^0 \), then \( \chi(s, t) \simeq \lim_{\to} \chi^\prime_i \) is presentable by Proposition T.5.5.3.13. The same argument will apply when \( s = s_0 \), provided that we can show that the diagram \( \chi[(\{s_0\} \times T) \to T] \) takes values in \( \Pr^L \). In other words, we must show that for every edge \( t \to t^\prime \) in \( T \), the induced functor \( \chi(s_0, t) \to \chi(s_0, t^\prime) \) preserves small colimits. This is obvious if \( S = \emptyset \) (in that case, both \( \infty \)-categories are contractible). Otherwise, we can choose a vertex \( s \in S \) and the desired result follows from the left adjointability of the diagram \( \sigma \) considered above.

We next show that for every edge \( \alpha : (s, t) \to (s', t') \) in \( S \times T \), the induced functor \( \chi(\alpha) : \chi(s, t) \to \chi(s', t') \) preserves small colimits. We can factor \( \chi(\alpha) \) as a composition

\[
\chi(s, t) \xrightarrow{U} \chi(s, t^\prime) \xrightarrow{V} \chi(s', t').
\]

The functor \( V \) admits a right adjoint, since \( \chi \) satisfies \((c)\). It therefore suffices to show that \( U \) preserves small colimits. This was established above when \( t \to t' \) is an edge of \( T \). If \( t \) is the cone point of \( T^0 \), the desired result follows from Proposition T.5.5.3.13.

It remains to verify that \( \chi \) satisfies \((a)\) and \((b)\). Assertion \((b)\) follows immediately from Proposition T.5.5.3.13. To prove \((a)\), it will suffice (by Corollary T.5.5.3.4) to show that \( \chi^\prime_i \) is a limit diagram in \( \Pr^L \). According to Theorem T.5.5.3.18, this is equivalent to the condition that \( \chi^\prime_i \) is a limit diagram in \( \Cat_{\infty} \). This is true by construction for \( t \in T \), and follows in general using Lemma T.5.5.2.3.

### 4.7.6 Descent and the Beck-Chevalley Condition

Let \( f : A \to B \) be a homomorphism of commutative rings, and let \( M^0 \) be a \( B \)-module. The classical theory of descent is an attempt to answer the following question: under what circumstances can one find an \( A \)-module \( M \) and an isomorphism \( \eta : M \otimes_A B \simeq M^0 \)? A choice of such an isomorphism \( \eta \) determines an isomorphism of \( B \otimes_A B \)-modules

\[
\tau : B \otimes_A M^0 \simeq M^0 \otimes_A B
\]

(since both sides are canonically isomorphic to \( M \otimes_A (B \otimes_A B) \)). Moreover, the map \( \tau \) satisfies a “cocycle condition”: namely, it renders the diagram

\[
\begin{array}{ccc}
B \otimes_A M^0 \otimes_A B & \xrightarrow{\text{id} \otimes \tau} & B \otimes_A B \otimes_A M^0 \\
& \xrightarrow{\tau \otimes \text{id}} & M^0 \otimes_A B \otimes_A B
\end{array}
\]

commutative, where \( \tau' \) is given by \( \tau \) on the outer factors and the identity \( \text{id}_B \) on the middle factor. A descent datum is a pair \((M^0, \tau)\), where \( M^0 \) is a \( B \)-module and \( \tau : B \otimes_A M^0 \to M^0 \otimes_A B \) is an isomorphism of \( B \otimes_A B \)-modules making the above diagram commute. The collection of descent data can be organized into a category \( \text{Desc}(f) \), and the construction \( M \mapsto M \otimes_A B \) determines a functor \( F \) from the category of \( A \)-modules into \( \text{Desc}(f) \). A classical theorem of Grothendieck asserts that this functor is an equivalence of categories when \( f : A \to B \) is a faithfully flat morphism of commutative rings.

In this section, we will explain how to use the Barr-Beck theorem (Theorem 4.7.4.5) to set up an \( \infty \)-categorical version of the machinery of descent theory. We begin by recasting the problem. Let \( f : A \to B \) be a map of commutative rings. Taking the \( \check{\text{C}}ech \) nerve of \( f \) (in the opposite of the category of commutative rings), we obtain a cosimplicial commutative ring \( B^\bullet \), where \( B^n \) denotes the \( n \)th tensor power of \( B \) over \( A \). The category \( \text{Desc}(f) \) can be identified with the category of cosimplicial modules \( M^\bullet \) over \( B^\bullet \) satisfying the requirement that for every map \( [m] \to [n] \) in \( \Delta \), the induced map \( M^m \otimes_B B^n \to M^n \) is an isomorphism. Put another way, \( \text{Desc}(f)^{op} \) can be identified with the homotopy limit of a cosimplicial category \( C^\bullet \), where each \( C^n \) is given by the opposite of the category of modules over the commutative ring \( B^n \). In good cases (for example if \( f \) is faithfully flat), one can show that this homotopy limit is equivalent to the (opposite of the) category of \( A \)-modules. Our goal is to develop some general tools for proving results of this kind.
4.7. MONADS AND THE BARR-BECK THEOREM

Very broadly, we can state our main problem as follows: given a cosimplicial ∞-category C\bullet, we would like to understand the totalization lim_∞ C\bullet. There is an evident forgetful functor lim_∞ C\bullet \to C^0. By analogy with the situation considered above, it is natural to expect that an object of lim_∞ C\bullet can be identified with an object of C\bullet together with some sort of “descent data.” One way to articulate this idea precisely is to show that the forgetful functor lim_∞ C\bullet \to C^0 is monadic: that is, it exhibits lim_∞ C\bullet as the ∞-category LMod_T(C^0) for some monad T on C^0. This is true under very general assumptions (Proposition 4.7.6.1). Moreover, if we are willing to make some mild assumptions on C\bullet, then we can obtain an explicit description of the monad T (Theorem 4.7.6.2). Using this description, we can give a simple criterion for a functor C\bullet \to C\bullet to be an equivalence (Corollary 4.7.6.3).

We begin with a very general result about the limit of a diagram of ∞-categories.

**Proposition 4.7.6.1.** Let \mathcal{J} be a small ∞-category and let q : \mathcal{J} \to \mathcal{C}_{\text{at}_\infty} be a diagram having a limit C ∈ \mathcal{C}_{\text{at}_\infty}. Let 0 ∈ \mathcal{J} be an object and let C^0 = q(0). Suppose that the following conditions are satisfied:

1. The functor G : \mathcal{C} \to C^0 admits a left adjoint F.
2. For every object J ∈ \mathcal{J}, there exists a morphism 0 → J in \mathcal{J}.

Then the adjoint functors C^0 \overset{\alpha}{\leftarrow} \mathcal{C} satisfy the hypotheses of Theorem 4.7.4.5, so that \mathcal{C} is equivalent to the ∞-category of modules LMod_T(C^0) for the induced monad T ≃ G \circ F on C^0.

**Proof.** We first show that G is conservative. Let α : C → C' be a morphism in \mathcal{C} such that G(α) is an equivalence. Using condition (2), we deduce that the image of α in q(J) is an equivalence for each J ∈ \mathcal{J}, so that α is an equivalence.

Now suppose that X_\bullet is a G-split simplicial object of \mathcal{C}; we wish to prove that X_\bullet admits a colimit in \mathcal{C} which is preserved by G. The diagram q classifies a coCartesian fibration p : \mathcal{J} \to \mathcal{J}. According to Proposition T.3.3.3.1, we can identify \mathcal{C} with the full subcategory of Fun_\mathcal{J}(\mathcal{J}, \mathcal{J}) spanned by those sections of p which carry every morphism in \mathcal{J} to a p-coCartesian morphism in \mathcal{J}. In particular, we can identify X_\bullet with a functor X : \mathcal{J} × N(\Delta)^{op} → \mathcal{J}. We next prove:

(*) There exists a functor X ∈ Fun_\mathcal{J}(\mathcal{J} × N(\Delta)^{op}, \mathcal{J}) which is a p-left Kan extension of X.

In view of Lemma T.4.3.2.13, it will suffice to show that for each object J ∈ \mathcal{J}, the diagram

\[
\begin{array}{ccc}
\mathcal{J}/J × N(\Delta)^{op} & \to & \mathcal{J} \\
\downarrow p & & \downarrow p \\
(\mathcal{J}/J × N(\Delta)^{op})^p & \to & \mathcal{J}
\end{array}
\]

admits an extension as indicated which is a p-colimit diagram. Because the inclusion \{J\} × N(\Delta)^{op} ↪ \mathcal{J}/J × N(\Delta)^{op} is left cofinal, it suffices to construct a p-colimit diagram X^J : N(\Delta)^{op} → \mathcal{J}/J which extends to the composite map X^J : N(\Delta)^{op} × N(\Delta)^{op} \to q(J) ≃ \mathcal{J}/J. According to Proposition T.4.3.1.10, it suffices to show that the simplicial object X^J admits a colimit in q(J) = \mathcal{J}/J, and that this colimit is preserved by the functor q(J) → q(J') associated to each morphism in α : J → J' in \mathcal{J}. For this, it is sufficient to show that X^J extends to a split simplicial object of q(J). Using assumption (2), we can reduce to the case J = 0. We conclude by invoking the assumption that X_\bullet is G-split.

Let X be as in (*), so we can identify X with an augmented simplicial object of Fun_\mathcal{J}(\mathcal{J}, \mathcal{J}). It follows from Lemma 3.2.2.9 that this augmented simplicial object is a colimit diagram, which is obviously preserved by G. To complete the proof, it will suffice to show that this augmented simplicial object belongs to the full subcategory \mathcal{C} ⊆ Fun_\mathcal{J}(\mathcal{J}, \mathcal{J}). In other words, we must show that for every morphism α : J → J' in \mathcal{J}, the induced map X(J, [-1]) → X(J', [-1]) is p-coCartesian. This is a translation of the condition that the functor q(α) : q(J) → q(J') preserves the colimit of the simplicial object X^J (since X^J is split). □
In order to apply Proposition 4.7.6.1 in practice, we would like to understand the monad \( G \circ F \) on the \( \infty \)-category \( \mathcal{C}^0 \). For this, we specialize to the case where \( J = N(\Delta) \) (so that \( q : J \to \text{Cat}_\infty \) can be identified with a cosimplicial \( \infty \)-category \( \mathcal{C}^* \)). For each \( n \geq 0 \), we let \( d^0 \) denote the coface map \( \mathcal{C}^n \to \mathcal{C}^{n+1} \) associated to the inclusion \([n] \to [0] \star [n] \simeq [n + 1] \).

The main result of this section can be stated as follows:

**Theorem 4.7.6.2.** Let \( \mathcal{C}^* : N(\Delta) \to \text{Cat}_\infty \) be a cosimplicial \( \infty \)-category which satisfies the following property:

(*) For every map \( \alpha : [m] \to [n] \) in \( \Delta \), the induced diagram

\[
\begin{array}{ccc}
\mathcal{C}^m & \xrightarrow{d^0} & \mathcal{C}^{m+1} \\
\downarrow & & \downarrow \\
\mathcal{C}^n & \xrightarrow{d^0} & \mathcal{C}^{n+1}
\end{array}
\]

is left adjointable. In particular, each coface map \( d^0 : \mathcal{C}^n \to \mathcal{C}^{n+1} \) admits a left adjoint \( F(n) : \mathcal{C}^{n+1} \to \mathcal{C}^n \).

Let \( \mathcal{C} = \varprojlim \mathcal{C}^* \) be a totalization of \( \mathcal{C}^* \). Then:

1. The forgetful functor \( G : \mathcal{C} \to \mathcal{C}^0 \) admits a left adjoint \( F \).
2. The diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{G} & \mathcal{C}^0 \\
\downarrow & & \downarrow \quad \quad \quad \downarrow \quad \quad \quad \downarrow \\
\mathcal{C}^0 & \xrightarrow{d^0} & \mathcal{C}^1
\end{array}
\]

is left adjointable. That is, the canonical map \( F(0) \circ d^1 \to G \circ F \) is an equivalence of functors from \( \mathcal{C}^0 \) to itself.

3. The adjoint functors \( \mathcal{C}^0 \xrightarrow{F} \mathcal{C} \xleftarrow{G} \mathcal{C}^0 \) satisfy the conditions of Theorem 4.7.4.5, so that \( \mathcal{C} \) is equivalent to the \( \infty \)-category \( \text{LMod}_T(\mathcal{C}^0) \) of algebras over the monad \( T \simeq G \circ F \simeq F(0) \circ d^1 \).

Before giving the proof of Theorem 4.7.6.2, we describe our main application.

**Corollary 4.7.6.3.** Let \( \mathcal{C}^* : N(\Delta_+) \to \text{Cat}_\infty \) be an augmented cosimplicial \( \infty \)-category, and set \( \mathcal{C} = \mathcal{C}^{-1} \). Let \( G : \mathcal{C} \to \mathcal{C}^0 \) be the evident functor. Assume that:

1. The \( \infty \)-category \( \mathcal{C}^{-1} \) admits geometric realizations of \( G \)-split simplicial objects, and those geometric realizations are preserved by \( G \).
2. For every morphism \( \alpha : [m] \to [n] \) in \( \Delta_+ \), the diagram

\[
\begin{array}{ccc}
\mathcal{C}^m & \xrightarrow{d^0} & \mathcal{C}^{m+1} \\
\downarrow & & \downarrow \\
\mathcal{C}^n & \xrightarrow{d^0} & \mathcal{C}^{n+1}
\end{array}
\]

is left adjointable.

Then the canonical map \( \theta : \mathcal{C} \to \varprojlim_{n \in \Delta} \mathcal{C}^n \) admits a fully faithful left adjoint. If \( G \) is conservative, then \( \theta \) is an equivalence.
4.8. Tensor Products of ∞-Categories

Proof. Let \( D^\bullet : N(\Delta_+) \to \mathcal{C}_{\infty} \) be a limit of the diagram \( \mathcal{C}^\bullet | N(\Delta) \), so that we have a map of cosimplicial ∞-categories \( \alpha : \mathcal{C}^\bullet \to D^\bullet \) which induces the identity map from \( \mathcal{C}^n = D^n \) to itself for \( n \geq 0 \). Using (2) and Theorem 4.7.6.2, we conclude that the canonical map \( G' : D^{-1} \to D^0 = \mathcal{C}^0 \) admits a left adjoint \( T' \) which satisfies the hypotheses of Theorem 4.7.4.5. Applying Corollary 4.7.4.16 (and Remark 4.7.4.17) to the diagram

\[
\begin{array}{ccc}
\mathcal{C}^{-1} & \xrightarrow{U} & D^{-1} \\
\downarrow G & & \downarrow G' \\
\mathcal{C}^0, & & \mathcal{C}^0,
\end{array}
\]

we are reduced to showing that the canonical map \( G' F' \to GF \) is an equivalence of functors from \( \mathcal{C}^0 \) to itself. This is clear: assumption (2) and Theorem 4.7.6.2 allow us to identify both functors with the composition

\[
\mathcal{C}^0 \xrightarrow{d^1} \mathcal{C}^1 \xrightarrow{T} \mathcal{C}^0,
\]

where \( T \) is a left adjoint to the face map \( d^0 : \mathcal{C}^0 \to \mathcal{C}^1 \). \( \square \)

Proof of Theorem 4.7.6.2. Let \( \mathcal{C}^\bullet : N(\Delta_+) \to \mathcal{C}_{\infty} \) be a limit of the diagram \( \mathcal{C}^\bullet \). Let \( T : N(\Delta_+) \times \Delta^1 \to N(\Delta_+) \) be the functor given by the formula

\[
T([n], i) = \begin{cases} [n] & \text{if } i = 0 \\ [0] \star [n] \simeq [n + 1] & \text{if } i = 1. \end{cases}
\]

Let us regard the composite functor

\[
N(\Delta_+) \times \Delta^1 \xrightarrow{T} N(\Delta_+) \xrightarrow{\mathcal{C}^\bullet} \mathcal{C}_{\infty}
\]

as an augmented cosimplicial object \( X^\bullet \) of the ∞-category \( \text{Fun}(\Delta^1, \mathcal{C}_{\infty}) \). We claim that \( X^\bullet \) is a limit diagram in \( \text{Fun}(\Delta^1, \mathcal{C}_{\infty}) \). This is equivalent to the requirement that for \( i \in \{0, 1\} \), the restriction \( (\mathcal{C}^\bullet \circ T)|N(\Delta_+) \times \{i\} \) is a limit diagram. For \( i = 0 \), this follows from our construction of \( \mathcal{C}^\bullet \), and for \( i = 1 \) it follows from the observation that the augmented cosimplicial ∞-category \( (\mathcal{C}^\bullet \circ T)|N(\Delta_+) \times \{1\} \) is split.

Let \( X^\bullet = X^\bullet \) be the underlying cosimplicial object of \( \text{Fun}(\Delta^1, \mathcal{C}_{\infty}) \). Condition (\( \ast \)) is equivalent to the requirement that \( X^\bullet \) is a cosimplicial object of \( \text{Fun}^{LAd}(\Delta^1, \mathcal{C}_{\infty}) \). It follows from Corollary 4.7.5.18 that \( X^\bullet \) is an augmented cosimplicial object of \( \text{Fun}^{LAd}(\Delta^1, \mathcal{C}_{\infty}) \). Since \( X^{-1} \) is an object of \( \text{Fun}^{LAd}(\Delta^1, \mathcal{C}_{\infty}) \), we deduce that the forgetful functor \( G : \mathcal{C} \simeq \mathcal{C}^{-1} \to \mathcal{C}^0 \) admits a left adjoint. This proves (1). Assertion (2) is equivalent to the requirement that the map \( X^{-1} \to X^0 \) is a morphism of \( \text{Fun}^{LAd}(\Delta^1, \mathcal{C}_{\infty}) \), and assertion (3) follows immediately from Proposition 4.7.6.1. \( \square \)

4.8 Tensor Products of ∞-Categories

Our goal in this section is to study some specific examples of symmetric monoidal ∞-categories which play an important role in higher category theory. We begin in §4.8.1 by showing that the ∞-category \( \text{Pr}^L \) of presentable ∞-categories admits a symmetric monoidal structure: if \( \mathcal{C} \) and \( \mathcal{D} \) are presentable ∞-categories, then the tensor product \( \mathcal{C} \otimes \mathcal{D} \) is universal among presentable ∞-categories which receive a functor \( \mathcal{C} \times \mathcal{D} \to \mathcal{C} \otimes \mathcal{D} \) which preserves small colimits separately in each variable.

Let \( \text{Sp} \) denote the ∞-category of spectra introduced in §1.4.3. Then \( \text{Sp} \) is a presentable stable ∞-category, which we can regard as an object of \( \text{Pr}^L \). In §4.8.2, we will show that \( \text{Sp} \) admits the structure of a commutative algebra object of \( \text{Pr}^L \) (in an essentially unique way). In other words, the ∞-category of spectra admits a symmetric monoidal structure, where the tensor product

\[
\otimes : \text{Sp} \times \text{Sp} \to \text{Sp}
\]
preserves small colimits separately in each variable. We will refer to this structure as the \textit{smash product symmetric monoidal structure}. The theory of commutative and associative algebras in \text{Sp} will be the subject of Chapter 7.

The symmetric monoidal structure on \( \mathcal{P}^l \) has a number of other applications. Suppose that \( \mathcal{C} \) is an associative algebra object of \( \mathcal{P}^l \): that is, \( \mathcal{C} \) is a presentable monoidal \( \infty \)-category for which the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves small colimits separately in each variable. Let \( \mathcal{A} \) be an associative algebra object of \( \mathcal{C} \). In §4.3.2, we saw that the \( \infty \)-category \( \text{RMod}_\mathcal{A}(\mathcal{C}) \) is naturally left-tensored over the monoidal \( \infty \)-category \( \mathcal{C} \). In §4.8.3, we will show that the construction \( \mathcal{A} \mapsto \text{RMod}_\mathcal{A}(\mathcal{C}) \) can be regarded as a functor \( \text{Alg}(\mathcal{C}) \to \text{LMod}_\mathcal{C}(\mathcal{P}^l) \). We will make a detailed study of this functor in §4.8.5. Our analysis relies on the fact that \( \text{RMod}_\mathcal{A}(\mathcal{C}) \) can be characterized (as an \( \infty \)-category left-tensored over \( \mathcal{C} \)) by two different universal properties, which we will verify in §4.8.4.

In the special case where \( \mathcal{C} \) is a symmetric monoidal \( \infty \)-category, both \( \text{Alg}(\mathcal{C}) \) and \( \text{LMod}_\mathcal{C}(\mathcal{P}^l) \) inherit symmetric monoidal structures, and the construction \( \mathcal{A} \mapsto \text{RMod}_\mathcal{A}(\mathcal{C}) \) is a symmetric monoidal functor. This observation will play an important role in the study of algebras over the little cubes \( \infty \)-operads \( \mathbf{E}_k^\otimes \) which we will undertake in Chapter 5.

### 4.8.1 Tensor Products of \( \infty \)-Categories

In §2.4.1, we saw that any \( \infty \)-category \( \mathcal{C} \) which admits finite products can be regarded as a symmetric monoidal \( \infty \)-category, where the symmetric monoidal structure on \( \mathcal{C} \) is given by the Cartesian product functor \( \mathcal{C} \times \mathcal{C} \to \mathcal{C} \). In particular, the \( \infty \)-category \( \mathbf{Cat}_\infty \) of (small) \( \infty \)-categories is endowed with a symmetric monoidal structure. The commutative algebra objects of \( \mathbf{Cat}_\infty \) can be thought of as symmetric monoidal \( \infty \)-categories (Remark 2.4.2.6). In practice, it is often convenient to work not with an arbitrary symmetric monoidal \( \infty \)-categories (§4.8.1), we saw that any \( \infty \)-category \( \mathcal{K} \) consists of a map \( \langle \eta \rangle : \langle n \rangle \to \langle m \rangle \) and a collection of functors \( \eta_j : \prod_{\alpha(i) = j} X_i \to Y_j \).

Let \( \mathcal{P}_0 \) denote the collection of all sets of simplicial sets, partially ordered by inclusion. We define a subcategory \( \mathbf{Cat}_\infty^\otimes \times \mathbf{N}(\mathcal{P}_0) \) as follows:

(i) The objects of \( \mathbf{Cat}_\infty^\otimes \times \mathbf{N}(\mathcal{P}_0) \) are finite sequences \([X_1, \ldots, X_n]\), where each \( X_i \) is an \( \infty \)-category.

(ii) Given a pair of objects \([X_1, \ldots, X_n], [Y_1, \ldots, Y_m]\) \( \in \mathbf{Cat}_\infty^\otimes \), a morphism from \([X_1, \ldots, X_n]\) to \([Y_1, \ldots, Y_m]\) consists of a map \( \alpha : \langle n \rangle \to \langle m \rangle \) and a collection of functors \( \eta_j : \prod_{\alpha(i) = j} X_i \to Y_j \).

Let \( \mathcal{P} \) denote the collection of all sets of simplicial sets, partially ordered by inclusion. We define a subcategory \( \mathbf{Cat}_\infty^\otimes \times \mathbf{N}(\mathcal{P}) \) as follows:

(iii) An object \(([X_1, \ldots, X_n], \mathcal{K}) \) of \( \mathbf{Cat}_\infty^\otimes \times \mathbf{N}(\mathcal{P}) \) belongs to \( \mathcal{M} \) if and only if each of the \( \infty \)-categories \( X_i \) admits \( \mathcal{K} \)-indexed colimits.
4.8. TENSOR PRODUCTS OF ∞-CATEGORIES

Let \( C \) follow that the symmetric monoidal structure on \( \text{homotopy equivalence} \) \( C \) of Corollary 4.8.1.4 is closed (see Definition 4.1.1.17): for every pair of objects \( K \)

\[
\prod_{\alpha(i) = j} X_i \to Y_j
\]

preserves \( \mathcal{K} \)-indexed colimits separately in each variable.

If \( \mathcal{K} \) is a set of simplicial sets, we let \( \text{Cat}_\infty(\mathcal{K})\circ \) denote the fiber product \( M \times_{N(P)} \{ \mathcal{K} \} \).

We will need the following technical result.

**Proposition 4.8.1.3.** Let \( M \) be defined as in Notation 4.8.1.2. Then the forgetful functor \( p : M \to N(\text{Fin}_*) \times N(P) \) is a coCartesian fibration.

**Corollary 4.8.1.4.** Let \( \mathcal{K} \) be a set of simplicial sets. Then the subcategory \( \text{Cat}_\infty(\mathcal{K})\circ \) is a symmetric monoidal \( \infty \)-category, and the inclusion \( \text{Cat}_\infty(\mathcal{X})\circ \hookrightarrow \text{Cat}_\infty^\circ \) is a lax symmetric monoidal functor.

**Proof.** It follows from Proposition 4.8.1.3 that the forgetful functor \( p : \text{Cat}_\infty(\mathcal{X})\circ \to N(\text{Fin}_*) \) is a coCartesian fibration. Moreover, there is a canonical isomorphism of simplicial sets \( \text{Cat}_\infty(\mathcal{X})\circ \simeq \text{Cat}_\infty(\mathcal{X})^n \), which is induced by the functor \( p \).

**Remark 4.8.1.5.** Suppose \( \mathcal{K} \) is a collection of sifted simplicial sets. Then, for each \( K \in \mathcal{K} \), a \( \mathcal{C}_1 \times \cdots \times \mathcal{C}_n \to \mathcal{D} \)

preserves \( K \)-indexed colimits if and only if it preserves \( K \)-indexed colimits separately in each variable. It follows that the symmetric monoidal structure on \( \text{Cat}_\infty(\mathcal{K}) \) described in Corollary 4.8.1.4 is Cartesian.

**Remark 4.8.1.6.** Let \( \mathcal{K} \) be a set of simplicial sets. Then the symmetric monoidal \( \infty \)-category \( \text{Cat}_\infty(\mathcal{K}) \) of Corollary 4.8.1.4 is closed (see Definition 4.1.1.17): for every pair of objects \( \mathcal{C}, \mathcal{D} \in \text{Cat}_\infty(\mathcal{K}), \) if we let \( \mathcal{E} \) denote the full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) spanned by those functors which preserve \( \mathcal{K} \)-indexed colimits, then the evaluation map

\[
\mathcal{C} \times \mathcal{E} \hookrightarrow \mathcal{C} \times \text{Fun}(\mathcal{C}, \mathcal{D}) \to \mathcal{D}
\]

preserves \( \mathcal{K} \)-indexed colimits separately in each variable and induces, for each object \( \mathcal{T} \in \text{Cat}_\infty(\mathcal{K}) \), a homotopy equivalence

\[
\text{Map}_{\text{Cat}_\infty(\mathcal{K})}(\mathcal{T}, \mathcal{E}) \to \text{Map}_{\text{Cat}_\infty(\mathcal{K})}(\mathcal{C} \otimes \mathcal{T}, \mathcal{D}).
\]

The proof of Proposition 4.8.1.3 will require a bit of notation.

**Notation 4.8.1.7.** Let \( \mathcal{C}_1 \) and \( \mathcal{C}_2 \) be \( \infty \)-categories. Given a pair of collections of diagrams \( \mathcal{R}_1 = \{ \eta_\alpha : K_{\alpha}^\circ \to \mathcal{C}_1 \} \) and \( \mathcal{R}_2 = \{ \eta_\beta : K_{\beta}^\circ \to \mathcal{C}_2 \} \), we let \( \mathcal{R}_1 \boxtimes \mathcal{R}_2 \) denote the collection of all diagrams \( \tau : K^\circ \to \mathcal{C}_1 \times \mathcal{C}_2 \) satisfying one of the following conditions:

1. There exists an index \( \alpha \) and an object \( C_2 \in \mathcal{C}_2 \) such that \( K = K_\alpha \) and \( \tau \) is given by the composition

\[
K^\circ \simeq K_\alpha^\circ \times \{ C_2 \} \overset{\eta_\alpha}{\to} \mathcal{C}_1 \times \mathcal{C}_2.
\]

2. There exists an index \( \beta \) and an object \( C_1 \in \mathcal{C}_1 \) such that \( K = K_\beta \) and \( \tau \) is given by the composition

\[
K^\circ \simeq \{ C_1 \} \times K_\beta^\circ \overset{\eta_\beta}{\to} \mathcal{C}_1 \times \mathcal{C}_2.
\]
The operation $\boxtimes$ is coherently associative (and commutative). In other words, if for each $1 \leq i \leq n$ we are given an $\infty$-category $\mathcal{C}_i$ and a collection $R_i$ of diagrams in $\mathcal{C}_i$, then we have a well-defined collection $R_1 \boxtimes \ldots \boxtimes R_n$ of diagrams in the product $\mathcal{C}_1 \times \ldots \times \mathcal{C}_n$, so there is no ambiguity in writing expressions such as $R_1 \boxtimes \ldots \boxtimes R_n$. In the case $n = 0$, we agree that this product coincides with the empty set of diagrams in the final $\infty$-category $\Delta^0$.

**Proof of Proposition 4.8.1.3.** We first show that $p$ is a locally coCartesian fibration. Suppose given an object $((\mathcal{C}_1, \ldots, \mathcal{C}_n), \mathcal{K})$ in $\mathcal{M}$, and a morphism $\alpha : ((m), \mathcal{K}') \to ((m), \mathcal{K}')$ in $\mathcal{M}$ (T.5.3.6 for an explanation of this notation). It follows from Proposition T.5.3.6.2 that the functors $\{f_j\}_{1 \leq j \leq m}$ assemble to a locally p-coCartesian morphism in $\mathcal{M}$. Supplying a lift of $\alpha$ is tantamount to choosing a collection of functors

$$f_j : \prod_{\alpha(i) = j} \mathcal{C}_i \to \mathcal{D}_j$$

for $1 \leq j \leq m$, such that $\mathcal{D}_j$ admits $\mathcal{K}'$-indexed colimits, and $f_j$ preserves $\mathcal{K}$-indexed colimits separately in each variable. For $1 \leq i \leq n$, let $\mathcal{R}_i$ denote the collection of all colimit diagrams in $\mathcal{C}_i$, indexed by simplicial sets belonging to $\mathcal{K}$. We now set $\mathcal{D}_j = \mathcal{F}^{\mathcal{K}'}_\mathcal{R}(\prod_{\alpha(i) = j} \mathcal{C}_i)$, where $\mathcal{R}$ denotes the $\boxtimes$-product of $\{\mathcal{R}_j\}_{\alpha(i) = j}$ (we refer the reader to §T.5.3.6 for an explanation of this notation). It follows from Proposition T.5.3.6.2 that the functors $\{f_j\}_{1 \leq j \leq m}$ assemble to a locally p-coCartesian morphism in $\mathcal{M}$.

To complete the proof that $p$ is a coCartesian fibration, it will suffice to show that the locally $p$-coCartesian morphisms are closed under composition (Proposition 2.4.2.8). In view of the construction of locally $p$-coCartesian morphisms given above, this follows immediately from Proposition T.5.3.6.11.

**Remark 4.8.1.8.** The coCartesian fibration $p$ of Proposition 4.8.1.3 classifies a functor $\mathcal{M}(\mathcal{F}(\mathcal{K}), \mathcal{M})$ which may identify with a functor from $\mathcal{M}$ to the $\infty$-category of commutative monoid objects of $\mathcal{C}_\infty$. Consequently, we obtain a functor from $\mathcal{M}$ to the $\infty$-category of symmetric monoidal $\infty$-categories. In other words, if $\mathcal{K} \subseteq \mathcal{K}'$, then $\mathcal{K}$ is a collection of simplicial sets, then we obtain a symmetric monoidal functor from $\mathcal{C}_\infty(\mathcal{K})$ to $\mathcal{C}_\infty(\mathcal{K}')$. It follows from the proof of Proposition 4.8.1.3 that this functor is given on objects by the formula $\mathcal{C} \mapsto \mathcal{F}^{\mathcal{K}'}_\mathcal{K}(\mathcal{C})$.

**Remark 4.8.1.9.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad, so that $\mathcal{A}(\mathcal{O}_\infty)$ can be identified with the $\infty$-category of $\mathcal{O}$-monoidal $\infty$-categories (Example 2.4.2.4 and Proposition 2.4.2.5). Unwinding the definitions, we see that $\mathcal{A}(\mathcal{O}_\infty)(\mathcal{K})$ can be identified with the subcategory of $\mathcal{A}(\mathcal{O}_\infty)$ spanned by the $\mathcal{O}$-monoidal $\infty$-categories which are compatible with $\mathcal{K}$-indexed colimits, and those $\mathcal{O}$-monoidal functors which preserve $\mathcal{K}$-indexed colimits.

Given an inclusion $\mathcal{K} \subseteq \mathcal{K}'$ of sets of simplicial sets, the induced inclusion

$$\mathcal{A}(\mathcal{O}_\infty)(\mathcal{K}') \subseteq \mathcal{A}(\mathcal{O}_\infty)(\mathcal{K})$$

admits a left adjoint, given by composition with the symmetric monoidal functor $\mathcal{F}^{\mathcal{K}'}_\mathcal{K}$. Contemplating the unit of this adjunction, we arrive at the following result:

**Proposition 4.8.1.10.** Let $\mathcal{K} \subseteq \mathcal{K}'$ be collections of simplicial sets and $q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes$ a coCartesian fibration of $\infty$-operads. Assume that the $\mathcal{O}$-monoidal structure on $\mathcal{E}$ is compatible with $\mathcal{K}$-indexed colimits. Then there exists a $\mathcal{O}$-monoidal functor $\mathcal{F}^\mathcal{K}_\mathcal{K}(\mathcal{E})$ with the following properties:

1. The $\mathcal{O}$-monoidal structure on $\mathcal{D}^\otimes$ is compatible with $\mathcal{K}'$-indexed colimits.
2. For each $X \in \mathcal{O}$, the underlying functor $f_X : \mathcal{E}_X \to \mathcal{D}_X$ preserves $\mathcal{K}$-indexed colimits.
3. For every $\mathcal{K}$-indexed colimit $\mathcal{D}_X$ in the $\mathcal{O}$-monoidal structure on $\mathcal{E}$ and every object $X \in \mathcal{O}$, composition with $f_X$ induces an equivalence of $\infty$-categories $\mathcal{F}^{\mathcal{K}_\mathcal{K}}(\mathcal{D}_X, \mathcal{E}) \to \mathcal{F}^{\mathcal{K}_\mathcal{K}}(\mathcal{E}_X, \mathcal{E})$. In particular, $f$ induces an identification $\mathcal{D}_X \simeq \mathcal{F}^{\mathcal{K}_\mathcal{K}}(\mathcal{E}_X, \mathcal{E})$, and is therefore fully faithful (Proposition T.5.3.6.2).
4.8. TENSOR PRODUCTS OF ∞-CATEGORIES

527

(4) If \( C^\otimes \to \mathcal{O}^\otimes \) is a coCartesian fibration of \( \infty \)-operads which is compatible with \( \mathcal{K}' \)-indexed colimits, then the induced map \( \text{Alg}_D(\mathcal{E}) \to \text{Alg}_C(\mathcal{E}) \) induces an equivalence of \( \infty \)-categories from the full subcategory of \( \text{Alg}_D(\mathcal{E}) \) spanned by those algebra objects \( A \) such that each \( A_X : \mathcal{D}_X \to \mathcal{E}_X \) preserves \( \mathcal{K}' \)-indexed colimits to the full subcategory of \( \text{Alg}_C(\mathcal{E}) \) spanned by those algebra objects \( B \) such that each \( B_X : \mathcal{E}_X \to \mathcal{E}_X \) preserves \( \mathcal{K} \)-indexed colimits.

Variant 4.8.1.11. In Notation 4.8.1.2, we can replace \( \text{Cat}_\infty \) by the (very large) \( \infty \)-category \( \widehat{\text{Cat}}_\infty \) of \( \infty \)-categories which are not necessarily small, and \( P \) by the collection \( \hat{P} \) of not necessarily small collections of simplicial sets. We then obtain a coCartesian fibration

\[ \hat{M} \to N(\mathcal{J}_{\text{Fin}_*}) \times N(\hat{P}). \]

We denote the fiber of this map over an object \( K \in \hat{P} \) by \( \widehat{\text{Cat}}_\infty(K)^\otimes \).

Let \( \mathcal{C} \) be a symmetric monoidal category. The category \( \text{Fun}(\mathcal{C}^{op}, \text{Set}) \) of presheaves of sets on \( \mathcal{C} \) then inherits a symmetric monoidal structure, which is characterized by the following assertions:

1. The Yoneda embedding \( \mathcal{C} \to \text{Fun}(\mathcal{C}^{op}, \text{Set}) \) is a monoidal functor.

2. The tensor product functor \( \otimes : \text{Fun}(\mathcal{C}^{op}, \text{Set}) \times \text{Fun}(\mathcal{C}^{op}, \text{Set}) \to \text{Fun}(\mathcal{C}^{op}, \text{Set}) \) preserves colimits separately in each variable.

The bifunctor \( \otimes : \text{Fun}(\mathcal{C}^{op}, \text{Set}) \times \text{Fun}(\mathcal{C}^{op}, \text{Set}) \to \text{Fun}(\mathcal{C}^{op}, \text{Set}) \) is called the Day convolution product. More concretely, this operation is given by the composition

\[
\text{Fun}(\mathcal{C}^{op}, \text{Set}) \times \text{Fun}(\mathcal{C}^{op}, \text{Set}) \to \text{Fun}(\mathcal{C}^{op} \times \mathcal{C}^{op}, \text{Set} \times \text{Set}) \\
\phi \to \text{Fun}(\mathcal{C}^{op} \times \mathcal{C}^{op}, \text{Set}) \\
\phi' \to \text{Fun}(\mathcal{C}^{op}, \text{Set})
\]

where \( \phi \) is induced by the Cartesian product functor \( \text{Set} \times \text{Set} \to \text{Set} \), and \( \phi' \) is given by left Kan extension along the functor \( \mathcal{C}^{op} \times \mathcal{C}^{op} \to \mathcal{C}^{op} \) determined by the symmetric monoidal structure on \( \mathcal{C} \). This symmetric monoidal structure on \( \text{Fun}(\mathcal{C}^{op}, \text{Set}) \) is called the Day convolution product. We can use Proposition 4.8.1.10 to generalize the Day convolution product to the \( \infty \)-categorical setting. Taking \( \mathcal{K} \) to be empty, \( \mathcal{K}' \) to be the collection of all small simplicial sets, and \( \mathcal{O}^\otimes \) is the commutative \( \infty \)-operad, we deduce the following:

Corollary 4.8.1.12. Let \( \mathcal{C} \) be a small symmetric monoidal \( \infty \)-category. Then there exists a symmetric monoidal structure on the \( \infty \)-category \( \mathcal{P}(\mathcal{C}) \) of presheaves on \( \mathcal{C} \). It is characterized up to (symmetric monoidal) equivalence by the following properties:

1. The Yoneda embedding \( j : \mathcal{C} \to \mathcal{P}(\mathcal{C}) \) can be extended to a symmetric monoidal functor.

2. The tensor product \( \otimes : \mathcal{P}(\mathcal{C}) \times \mathcal{P}(\mathcal{C}) \to \mathcal{P}(\mathcal{C}) \) preserves small colimits separately in each variable.

Proof: The existence of the desired symmetric monoidal structures on \( \mathcal{P}(\mathcal{C}) \) and \( j \) follows from Proposition 4.8.1.10. The uniqueness follows from the universal property given in assertion (3) of Proposition 4.8.1.10.

Applying Proposition 4.8.1.10 in the case where \( \mathcal{K} \) is empty and \( \mathcal{K}' \) is the class of all small filtered simplicial sets, we deduce the following:

Corollary 4.8.1.13. Let \( \mathcal{C} \) be a small symmetric monoidal \( \infty \)-category. Then there exists a symmetric monoidal structure on the \( \infty \)-category \( \text{Ind}(\mathcal{C}) \) of \( \text{Ind} \)-objects on \( \mathcal{C} \). It is characterized up to (symmetric monoidal) equivalence by the following properties:

1. The Yoneda embedding \( j : \mathcal{C} \to \text{Ind}(\mathcal{C}) \) can be extended to a symmetric monoidal functor.
The tensor product $\otimes : \text{Ind}(\mathcal{C}) \times \text{Ind}(\mathcal{C}) \to \text{Ind}(\mathcal{C})$ preserves small filtered colimits separately in each variable.

Moreover, if $\mathcal{C}$ admits finite colimits, and the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves finite colimits separately in each variable, then assertion (2) can be strengthened as follows:

(2') The tensor product functor $\otimes : \text{Ind}(\mathcal{C}) \times \text{Ind}(\mathcal{C}) \to \text{Ind}(\mathcal{C})$ preserves small colimits separately in each variable.

Moreover, if $\mathcal{D}^\otimes$ is any symmetric monoidal $\infty$-category such that $\mathcal{D}$ admits small filtered colimits and the tensor product $\mathcal{D} \times \mathcal{D} \to \mathcal{D}$ preserves small filtered colimits, then the restriction functor $\text{Fun}(\mathcal{D}^\otimes)(\text{Ind}(\mathcal{C}), \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D})$ is an equivalence of $\infty$-categories.

**Proof.** Only assertion (2') requires proof. For each $D \in \text{Ind}(\mathcal{C})$, let $e_D$ denote the functor $C \mapsto C \otimes D$. Let $\mathcal{D}$ denote the full subcategory spanned by those objects $D \in \text{Ind}(\mathcal{C})$ such that the functor $e_D$ preserves small colimits separately in each variable. We wish to prove that $\mathcal{D} = \text{Ind}(\mathcal{C})$. Assertion (2) implies that the correspondence $D \mapsto e_D$ is given by a functor $\text{Ind}(\mathcal{C}) \to \text{Fun}(\text{Ind}(\mathcal{C}), \text{Ind}(\mathcal{C}))$ which preserves filtered colimits. Consequently, $\mathcal{D}$ is stable under filtered colimits in $\text{Ind}(\mathcal{C})$. It will therefore suffice to show that $\mathcal{D}$ contains the essential image of $j$.

Let $C \in \mathcal{C}$. Since the Yoneda embedding $j$ is a symmetric monoidal functor, we have a homotopy commutative diagram

$$
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{e_C} & \mathcal{C} \\
\downarrow j & & \downarrow j \\
\text{Ind}(\mathcal{C}) & \xrightarrow{e_j(C)} & \text{Ind}(\mathcal{C}).
\end{array}
$$

The desired result now follows from Proposition T.5.5.1.9, since $e_j(C)$ preserves filtered colimits and $j \circ e_C$ preserves finite colimits.

Let $\mathcal{K}$ be the collection of all small simplicial sets. Let us now consider the symmetric monoidal $\infty$-category $\hat{\text{Cat}}_\infty(\mathcal{K})$, whose objects are $\infty$-categories which admit small colimits and whose morphisms are functors which preserve small colimits. We let $\mathcal{P}^L$ denote the full subcategory of $\hat{\text{Cat}}_\infty(\mathcal{K})$ spanned by the presentable $\infty$-categories.

**Proposition 4.8.1.14.** Let $\mathcal{K}$ denote the collection of all small simplicial sets. The $\infty$-category $\mathcal{P}^L$ of presentable $\infty$-categories is closed under tensor products in $\hat{\text{Cat}}_\infty(\mathcal{K})$, and therefore inherits a symmetric monoidal structure (see Proposition 2.2.1.1).

**Proof.** Corollary 4.8.1.12 implies that the unit object of $\hat{\text{Cat}}_\infty(\mathcal{K})$ is given by $\mathcal{P}(\Delta^0) \simeq \mathcal{S}$, which is a presentable $\infty$-category. It will therefore suffice to show that if $\mathcal{C}$ and $\mathcal{C}'$ are two presentable $\infty$-categories, then their tensor product $\mathcal{C} \otimes \mathcal{C}'$ in $\hat{\text{Cat}}_\infty(\mathcal{K})$ is also presentable. If $\mathcal{C} = \mathcal{P}(\mathcal{C}_0)$ and $\mathcal{C}' = \mathcal{P}(\mathcal{C}'_0)$ for a pair of small $\infty$-categories $\mathcal{C}_0$ and $\mathcal{C}'_0$, then Corollary 4.8.1.12 yields an equivalence $\mathcal{C} \otimes \mathcal{C}' \simeq \mathcal{P}(\mathcal{C}_0 \times \mathcal{C}'_0)$, so that $\mathcal{C} \otimes \mathcal{C}'$ is presentable as desired. In view of Theorem T.5.5.1.1, every presentable $\infty$-category is a localization of an $\infty$-category of presheaves. It will therefore suffice to prove the following:

(*) Let $\mathcal{C}$ and $\mathcal{C}'$ be presentable $\infty$-categories, and assume that the tensor product $\mathcal{C} \otimes \mathcal{C}'$ is presentable.

Let $S$ be a (small) set of morphisms in $\mathcal{C}$. Then the tensor product $S^{-1} \mathcal{C} \otimes \mathcal{C}'$ is presentable.

To prove (*), we choose a (small) set of objects $M = \{C'_s\}$ which generates $\mathcal{C}'$ under colimits. Let $f : \mathcal{C} \times \mathcal{C}' \to \mathcal{C} \otimes \mathcal{C}'$ be the canonical map, and let $T$ be the collection of all morphisms in $\mathcal{C} \otimes \mathcal{C}'$ having the form $f(s \times \text{id}_{C'})$, where $s \in S$ and $C' \in M$. Consider now the composition

$$
g : S^{-1} \mathcal{C} \times \mathcal{C}' \subseteq \mathcal{C} \times \mathcal{C}' \xrightarrow{f} \mathcal{C} \otimes \mathcal{C}' \xrightarrow{T^{-1}} \mathcal{C} \otimes \mathcal{C}',
$$
4.8. TENSOR PRODUCTS OF $\infty$-CATEGORIES

where $L$ is a left adjoint to the inclusion $T^{-1}(\mathcal{C} \otimes \mathcal{C}') \subseteq \mathcal{C} \otimes \mathcal{C}'$. We claim that $g$ exhibits $T^{-1}(\mathcal{C} \otimes \mathcal{C}')$ as a tensor product of $S^{-1}\mathcal{C}$ with $\mathcal{C}'$. In other words, we claim that if $\mathcal{D}$ is an arbitrary $\infty$-category which admits small colimits, then composition with $g$ induces an equivalence

$$\text{Fun}_K(T^{-1}(\mathcal{C} \otimes \mathcal{C}'), \mathcal{D}) \to \text{Fun}_K(S^{-1}\mathcal{C} \times \mathcal{C}', \mathcal{D}).$$

The left hand side can be identified with the full subcategory of $\text{Fun}_K(\mathcal{C} \otimes \mathcal{C}', \mathcal{D})$ spanned by those functors which carry each morphism in $T$ to an equivalence. Under the equivalence

$$\text{Fun}_K(\mathcal{C} \otimes \mathcal{C}', \mathcal{D}) \simeq \text{Fun}_K(S^{-1}\mathcal{C} \times \mathcal{C}', \mathcal{D}),$$

this corresponds to the full subcategory spanned by those functors $F : \mathcal{C} \to \text{Fun}_K(\mathcal{C}', \mathcal{D})$ which carry each morphism in $S$ to an equivalence. This $\infty$-category is equivalent to $\text{Fun}_K(S^{-1}\mathcal{C}, \text{Fun}_K(\mathcal{C}', \mathcal{D})) \simeq \text{Fun}_K(\mathcal{C}, \text{Fun}_K(\mathcal{C}', \mathcal{D}))$, as desired. \qed

In §4.8.2, we will need a more explicit description of the tensor product on $\text{Pr}^L$.

**Lemma 4.8.1.15.** Let $\mathcal{C}$ and $\mathcal{D}$ be presentable $\infty$-categories. Then $\text{Fun}^R(\mathcal{C}^\text{op}, \mathcal{D})$ is a presentable $\infty$-category.

**Proof.** Using Theorem T.5.5.1.1 and the results of §T.5.5.4, we can choose a small $\infty$-category $\mathcal{C}'$, a small collection $S$ of morphisms in $\mathcal{P}(\mathcal{C}')$, and an equivalence $\mathcal{C} \simeq S^{-1}\mathcal{P}(\mathcal{C}')$. Then

$$\text{Fun}^R(\mathcal{P}(\mathcal{C}')^\text{op}, \mathcal{D}) \simeq \text{Fun}^L(\mathcal{P}(\mathcal{C}'), (\mathcal{D}^\text{op})^\text{op}) \simeq \text{Fun}(\mathcal{C}', \mathcal{D}^\text{op})^\text{op} \simeq \text{Fun}(\mathcal{C}^\text{op}, \mathcal{D})$$

is presentable by Proposition T.5.5.3.6, where the second equivalence is given by composition with the Yoneda embedding (Theorem T.5.1.5.6). For each morphism $\alpha \in S$, let $\mathcal{E}(\alpha)$ denote the full subcategory of $\text{Fun}^R(\mathcal{P}(\mathcal{C}'))^\text{op}, \mathcal{D})$ spanned by those functors which carry $\alpha$ to an equivalence in $\mathcal{D}$. Then $\text{Fun}^R(\mathcal{E}^\text{op}, \mathcal{D})$ is equivalent to the intersection $\bigcap_{\alpha \in S} \mathcal{E}(\alpha)$. In view of Lemma T.5.5.4.18, it will suffice to show that each $\mathcal{E}(\alpha)$ is a localization of $\text{Fun}^R(\mathcal{P}(\mathcal{C}'))^\text{op}, \mathcal{D})$. We now observe that $\mathcal{E}(\alpha)$ is given by a pullback diagram

$$\begin{array}{ccc}
\mathcal{E}(\alpha) & \to & \text{Fun}^R(\mathcal{P}(\mathcal{C}'))^\text{op}, \mathcal{D}) \\
\downarrow & & \downarrow \\
\mathcal{E}' & \to & \text{Fun}(\Delta^1, \mathcal{D}),
\end{array}$$

where $\mathcal{E}$ denotes the full subcategory of $\text{Fun}(\Delta^1, \mathcal{D})$ spanned by the equivalences. According to Lemma T.5.5.4.17, it will suffice to show that $\mathcal{E}$ is an accessible localization of $\text{Fun}(\Delta^1, \mathcal{D})$, which is clear. \qed

**Proposition 4.8.1.16.** Let $\mathcal{C}$ and $\mathcal{D}$ be presentable $\infty$-categories. Then there is a canonical equivalence

$$\mathcal{C} \otimes \mathcal{D} \simeq \text{Fun}^R(\mathcal{E}^\text{op}, \mathcal{D}).$$

**Proof.** Let $\mathcal{E}$ be an arbitrary presentable $\infty$-category, and let $\text{Fun}^L(\mathcal{C} \times \mathcal{D}, \mathcal{E})$ be the full subcategory of $\text{Fun}(\mathcal{C} \times \mathcal{D}, \mathcal{E})$ spanned by those functors which preserve small colimits separately in each variable. Then we have a canonical isomorphism $\text{Fun}^L(\mathcal{C} \times \mathcal{D}, \mathcal{E}) \simeq \text{Fun}^L(\mathcal{C}, \text{Fun}^L(\mathcal{C} \times \mathcal{D}, \mathcal{E})).$ Here the $\infty$-category $\text{Fun}^L(\mathcal{D}, \mathcal{E})$ is presentable (Proposition T.5.5.3.8). Using Corollary T.5.5.2.9 and Proposition T.5.2.6.3, we can identify $\text{Fun}^L(\mathcal{D}, \mathcal{E})$ with the full subcategory of $\text{Fun}^R(\mathcal{E}, \mathcal{D})^\text{op}$ spanned by those functors which are accessible. Consequently, we get a fully faithful embedding

$$\text{Fun}^L(\mathcal{C} \times \mathcal{D}, \mathcal{E}) \to \text{Fun}^L(\mathcal{C}, \text{Fun}^L(\mathcal{E}, \mathcal{D}^\text{op}))$$

$$\simeq \text{Fun}^L(\mathcal{C}, \text{Fun}^L(\mathcal{E}^\text{op}, \mathcal{D}^\text{op}))$$

$$\simeq \text{Fun}^L(\mathcal{E}^\text{op}, \text{Fun}^L(\mathcal{C}, \mathcal{D}^\text{op}))$$

$$\simeq \text{Fun}^R(\mathcal{E}, \text{Fun}^R(\mathcal{E}^\text{op}, \mathcal{D}^\text{op}))^\text{op}.$$
whose essential image consists of the collection of accessible functors from \( \mathcal{E} \) to \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{D}) \). We now apply Lemma 4.8.1.15 to conclude that \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{E}) \) is presentable, so that (using Corollary T.5.5.2.9 and Proposition T.5.2.6.3 again) \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{E}) \) can be identified with \( \text{Fun}^L(\text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{D}), \mathcal{E}) \). It follows that \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{D}) \) and \( \mathcal{E} \otimes \mathcal{D} \) corepresent the same functor on \( \mathcal{P} \mathcal{R}^L \) and are therefore canonically equivalent.

**Remark 4.8.1.17.** The symmetric monoidal structure on \( \mathcal{P} \mathcal{R}^L \) described in Proposition 4.8.1.14 is closed (see Definition 4.1.1.17): for every pair of presentable \( \infty \)-categories \( \mathcal{E} \) and \( \mathcal{D} \), the \( \infty \)-category \( \text{Fun}^L(\mathcal{E}, \mathcal{D}) \) of colimit-preserving functors from \( \mathcal{E} \) to \( \mathcal{D} \) (which is presentable by Proposition T.5.5.3.8) is equipped with a map \( \mathcal{E} \otimes \text{Fun}^L(\mathcal{E}, \mathcal{D}) \to \mathcal{D} \) which exhibits \( \text{Fun}^L(\mathcal{E}, \mathcal{D}) \) as an exponential of \( \mathcal{D} \) by \( \mathcal{E} \).

**Example 4.8.1.18.** Let \( \mathcal{X} \) and \( \mathcal{Y} \) be \( \infty \)-topoi. Then \( \mathcal{X} \otimes \mathcal{Y} \) is an \( \infty \)-topos, and can be identified with the (Cartesian) product of \( \mathcal{X} \) and \( \mathcal{Y} \) in the \( \infty \)-category of \( \infty \)-topoi. For a proof of a slightly weaker assertion, we refer the reader to Theorem T.7.3.3.9. The general statement can be proven using a similar argument.

**Example 4.8.1.19.** Remark 4.8.1.8 implies that the \( \infty \)-category \( \mathcal{S} = \mathcal{P}(\Delta^0) \) is a unit object of \( \mathcal{P} \mathcal{R}^L \). In particular, for every presentable \( \infty \)-category \( \mathcal{E} \) we have canonical equivalences \( \mathcal{E} \simeq \mathcal{E} \otimes \mathcal{S} \simeq \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{S}) \). The essential surjectivity of the composition is a restatement of the representability criterion of Proposition T.5.5.2.2.

**Example 4.8.1.20.** Recall that, for every \( \infty \)-category \( \mathcal{C} \), the \( \infty \)-category \( \mathcal{C}_* \) of pointed objects of \( \mathcal{C} \) is defined to be the full subcategory of \( \text{Fun}(\Delta^1, \mathcal{C}) \) spanned by those functors \( F : \Delta^1 \to \mathcal{C} \) for which \( F(0) \) is a final object of \( \mathcal{C} \). The canonical isomorphism of simplicial sets \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{D}_*) \simeq \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{D})_* \) induces an equivalence \( \mathcal{E} \otimes \mathcal{D}_* \simeq (\mathcal{E} \otimes \mathcal{D})_* \) for every pair of presentable \( \infty \)-categories \( \mathcal{E}, \mathcal{D} \in \text{LPr} \). In particular, we have a canonical equivalence \( \mathcal{E} \otimes \mathcal{S}_* \simeq \mathcal{E}_* \).

**Example 4.8.1.21.** Let \( n \geq -2 \) be an integer, and let \( \tau_{\leq n} \mathcal{S} \) denote the full subcategory of \( \mathcal{S} \) spanned by the \( n \)-truncated spaces. For any presentable \( \infty \)-category \( \mathcal{E} \), we can identify \( \mathcal{E} \otimes \tau_{\leq n} \mathcal{S} \) with the \( \infty \)-category \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \tau_{\leq n} \mathcal{S}) \). Under the Yoneda equivalence \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{S}) \simeq \mathcal{E} \), \( \text{Fun}^R(\mathcal{E}^{\text{op}}, \tau_{\leq n} \mathcal{S}) \) corresponds to the full subcategory of \( \mathcal{E} \) spanned by those objects \( C \) such that \( \text{Map}_{\mathcal{E}}(C', C) \) is \( n \)-truncated, for each \( C' \in \mathcal{E} \). In other words, we have a canonical equivalence \( \mathcal{E} \otimes \tau_{\leq n} \mathcal{S} \simeq \tau_{\leq n} \mathcal{E} \).

**Example 4.8.1.22.** Let \( \text{Sp} \) denote the \( \infty \)-category of spectra. Then \( \text{Sp} \) can be identified with a homotopy limit of the tower

\[
\ldots \Omega \mathcal{S}_* \xrightarrow{\Omega} \mathcal{S}_* \xrightarrow{\Omega} \mathcal{S}_*.
\]

Consequently, for every presentable \( \infty \)-category \( \mathcal{E} \), we have equivalences

\[
\mathcal{E} \otimes \text{Sp} \simeq \text{Fun}^R(\mathcal{E}^{\text{op}}, \text{Sp}) \simeq \text{holim}\{\text{Fun}^R(\mathcal{E}^{\text{op}}, \mathcal{S}_*)\} \simeq \text{holim}\{\mathcal{E}_*\} \simeq \text{Sp}(\mathcal{E}),
\]

where \( \text{Sp}(\mathcal{E}) \) is defined as in §1.4.2.

**Remark 4.8.1.23.** Combining Proposition 4.8.1.16 with Theorem T.5.5.3.18, we conclude that the bifunctor \( \otimes : \mathcal{P} \mathcal{R}^L \times \mathcal{P} \mathcal{R}^L \to \mathcal{P} \mathcal{R}^L \) preserves small colimits separately in each variable (remember that \( \text{colimits in } \mathcal{P} \mathcal{R}^L \) can also be computed as \( \text{limits in } \mathcal{P} \mathcal{R} \), which are computed by forming limits in \( \text{Cat}_{\text{fg}} \) by Theorem T.5.5.3.18). Alternatively, one can observe that \( \mathcal{P} \mathcal{R}^L \) is actually a closed monoidal category, with internal mapping objects given by \( \text{Fun}^L(\mathcal{E}, \mathcal{D}) \) (see Proposition T.5.5.3.8).

**4.8.2 Smash Products of Spectra**

Let \( \text{Sp} \) denote the \( \infty \)-category of spectra (as defined in §1.4.3). The homotopy category \( \text{hSp} \) can be identified with the classical stable homotopy category. Given a pair of spectra \( X, Y \in \text{hSp} \), one can define a new spectrum called the smash product of \( X \) and \( Y \). The smash product operation determines a monoidal structure on \( \text{hSp} \). In this section, we will show that this monoidal structure is determined by a monoidal structure which exists on the \( \infty \)-category \( \text{Sp} \) itself. There are at least three ways to see this.
Choose a simplicial model category \( A \) equipped with a compatible monoidal structure, whose underlying \( \infty \)-category is equivalent to \( \text{Sp} \). For example, we can take \( A \) to be the category of \textit{symmetric spectra} (see [73]). According to Proposition 4.1.3.10, the underlying \( \infty \)-category \( N(A)^{\infty} \approx \text{Sp} \) is endowed with a symmetric monoidal structure. The advantage of this perspective is that it permits us to easily compare the algebras and modules considered in this paper with more classical approaches to the theory of structured ring spectra. For example, Theorem 4.1.4.4 implies that \( \text{Alg}(\text{Sp}) \) is (equivalent to) the \( \infty \)-category underlying the model category of algebras in symmetric spectra (that is, strictly associative monoids in \( A \)); see Example 4.1.4.6.

The main disadvantage of this approach is that it seems to require auxiliary data (namely, a strictly associative model for the smash product functor), which could be supplied in many different ways. From a conceptual point of view, the existence of such a model ought to be irrelevant: the purpose of higher category theory is to provide a formalism which allows us to avoid assumptions like strict associativity.

Let \( \text{Fun}^L(\text{Sp}, \text{Sp}) \) denote the full subcategory of \( \text{Fun}(\text{Sp}, \text{Sp}) \) spanned by those functors from \( \text{Sp} \) to \( \text{Sp} \) which preserve small colimits. Corollary 1.4.4.6 asserts that evaluation on the sphere spectrum yields an equivalence of \( \infty \)-categories \( \text{Fun}^L(\text{Sp}, \text{Sp}) \to \text{Sp} \). On the other hand, since \( \text{Fun}^L(\text{Sp}, \text{Sp}) \) is stable under composition in \( \text{Fun}(\text{Sp}, \text{Sp}) \), the composition monoidal structure on \( \text{Fun}(\text{Sp}, \text{Sp}) \) induces a monoidal structure on \( \text{Fun}^L(\text{Sp}, \text{Sp}) \). This definition has the virtue of being very concrete (the smash product operation is simply given by composition of functors), and it allows us to identify the algebra objects of \( \text{Fun}^L(\text{Sp}, \text{Sp}) \); they are precisely the colimit-preserving monads on the \( \infty \)-category \( \text{Sp} \) (for an application of this last observation, see Theorem 7.1.2.1). The disadvantage of this definition is that it is very "associative" in nature, and therefore does not generalize easily to show that \( \text{Sp} \) is a \textit{symmetric} monoidal \( \infty \)-category, as we will show below.

Let \( \mathcal{P}_L \) be the \( \infty \)-category whose objects are presentable \( \infty \)-categories and whose morphisms are colimit-preserving functors (see §3.5.5.3), and let \( \mathcal{P}_L^{\text{St}} \) be the full subcategory of \( \mathcal{P}_L \) spanned by those presentable \( \infty \)-categories which are stable. In §4.8.1, we showed that there is a symmetric monoidal structure on \( \mathcal{P}_L^{\text{St}} \). We will show that the full subcategory \( \mathcal{P}_L^{\text{St}} \) inherits a symmetric monoidal structure from that of \( \mathcal{P}_L \). The commutative algebra objects of \( \mathcal{P}_L^{\text{St}} \) can be identified with symmetric monoidal \( \infty \)-categories \( \mathcal{C} \) which are stable, presentable, and have the property that the bifunctor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves small colimits separately in each variable. We will see that \( \text{Sp} \) is the unit object of \( \mathcal{P}_L^{\text{St}} \) (with respect to its tensor structure). It follows from Proposition 3.2.1.8 that \( \text{Sp} \) can be endowed with the structure of a commutative algebra object of \( \mathcal{P}_L^{\text{St}} \), and in fact is \textit{initial} among such algebra objects. This establishes not only the existence of a symmetric monoidal structure on \( \text{Sp} \), but also a universal property which can be used to prove its uniqueness (Corollary 4.8.2.19).

We will adopt approach (S3). We begin with some general remarks concerning idempotent objects of monoidal \( \infty \)-categories.

**Definition 4.8.2.1.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category with unit object \( 1 \). We will say that a map \( e : 1 \to E \) is an \textit{idempotent object} of \( \mathcal{C} \) if the induced maps

\[
E \simeq E \otimes 1 \xrightarrow{\text{id} \otimes e} E \otimes E \quad E \simeq 1 \otimes E \xrightarrow{e \otimes \text{id}} E \otimes E
\]

are equivalences in \( \mathcal{C} \).

**Remark 4.8.2.2.** In the situation of Definition 4.8.2.1, we will often abuse terminology and simply say that \( E \) is an idempotent object of \( \mathcal{C} \), or that \( e : 1 \to E \) exhibits \( E \) \textit{as an idempotent object of} \( \mathcal{C} \).

**Example 4.8.2.3.** Let \( \mathcal{C} \) be an \( \infty \)-category. Then the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) is a strict monoidal \( \infty \)-category via composition (that is, composition endows \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) with the structure of a simplicial monoid.
see Example 4.1.4.7). An idempotent object of \( \text{Fun}(\mathcal{C}, \mathcal{C}) \) is a functor \( L : \mathcal{C} \to \mathcal{C} \) equipped with a natural transformation \( e : \text{id}_{\mathcal{C}} \to L \) such that the induced maps

\[
L = L \circ \text{id}_{\mathcal{C}} \to L \circ L \quad L = \text{id}_{\mathcal{C}} \circ L \to L \circ L
\]

are equivalences in \( \text{Fun}(\mathcal{C}, \mathcal{C}) \). This is equivalent to the assertion that \( L \) is a localization functor from \( \mathcal{C} \) to itself (see Proposition T.5.2.7.4).

**Proposition 4.8.2.4.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category and let \( e : 1 \to E \) be a morphism in \( \mathcal{C} \). The following conditions are equivalent:

1. The map \( e \) exhibits \( E \) as an idempotent object of \( \mathcal{C} \).
2. For every \( \infty \)-category \( \mathcal{M} \), let \( l_{E} : \mathcal{M} \to \mathcal{M} \) be the functor given by tensor product with \( E \in \mathcal{C} \), so that \( e \) induces a natural transformation \( \alpha_{\mathcal{M}} : \text{id}_{\mathcal{M}} \to l_{E} \). Then each of the natural transformations \( \alpha_{\mathcal{M}} \) exhibits \( l_{E} \) as a localization functor on \( \mathcal{M} \).
3. Let \( l_{E} : \mathcal{C} \to \mathcal{C} \) be the functor given by left tensor product with \( E \). Then \( e \) induces a functor \( \alpha : \text{id}_{\mathcal{C}} \to l_{E} \) which exhibits \( l_{E} \) as a localization functor on \( \mathcal{C} \).

**Proof.** The implication (1) \( \Rightarrow \) (2) follows from Proposition T.5.2.7.4 and the implication (2) \( \Rightarrow \) (3) is obvious. Assume that (3) is satisfied. Then Proposition T.5.2.7.4 implies that the transformation \( \alpha : \text{id}_{\mathcal{C}} \to l_{E} \) induces equivalences of functors \( l_{E} \to l_{E}^{\mathcal{C}} \). Evaluating these functors at the unit object of \( \mathcal{C} \), we deduce that the two natural maps \( E \to E \otimes E \) are equivalences. \( \square \)

**Remark 4.8.2.5.** Let \( e : 1 \to E \) be an idempotent object of a monoidal \( \infty \)-category \( \mathcal{C} \) and let \( L : \mathcal{C} \to \mathcal{C} \) be the localization functor given by tensor product with \( E \). Suppose that \( e \) admits a left inverse. Then \( 1 \) is a retract of \( E \). Since \( E \) is \( L \)-local, we conclude that \( 1 \) is \( L \)-local. Thus \( e \) is an \( L \)-equivalence between \( L \)-local objects, and therefore an equivalence.

In this section, we will be primarily interested in idempotent objects of symmetric monoidal \( \infty \)-categories.

**Remark 4.8.2.6.** Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category. Then a morphism \( e : 1 \to E \) in \( \mathcal{C} \) exhibits \( E \) as an idempotent object of \( \mathcal{C} \) if and only if the induced map \( \text{id}_{E} \otimes e : E \to E \otimes E \) is an equivalence; the symmetry of \( \mathcal{C} \) guarantees that \( e \otimes \text{id}_{E} \) is homotopic to \( \text{id}_{E} \otimes e \).

**Proposition 4.8.2.7.** Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category and let \( e : 1 \to E \) be an idempotent object of \( \mathcal{C} \). Let \( L : \mathcal{C} \to \mathcal{C} \) be the localization functor given by \( C \mapsto E \otimes C \) (see Proposition 4.8.2.4). Then \( L \) is compatible with the symmetric monoidal structure on \( \mathcal{C} \), so that \( L \mathcal{C} \) inherits a symmetric monoidal structure (see Proposition 2.2.1.9).

**Proof.** Let \( f : C \to C' \) be an \( L \)-equivalence and let \( D \in \mathcal{C} \); we wish to show that the induced map \( C \otimes D \to C' \otimes D \) is an \( L \)-equivalence. In other words, we wish to show that \( f \) induces an equivalence \( E \otimes C \otimes D \to E \otimes C' \otimes D \). This is clear, since \( f \) induces an equivalence \( E \otimes C \to E \otimes C' \).

In the situation of Proposition 4.8.2.7, the inclusion \( (L\mathcal{C})^{\otimes} \to \mathcal{C}^{\otimes} \) is a fully faithful embedding of \( \infty \)-operads, which induces a fully faithful embedding \( \text{CAlg}(L\mathcal{C}) \to \text{CAlg}(\mathcal{C}) \) whose essential image is the collection of commutative algebra objects \( A \in \text{CAlg}(\mathcal{C}) \) such that \( e \) induces an equivalence \( A \to E \otimes E \). Note that the unit object of \( L \mathcal{C} \) is given by \( L1 \simeq E \). It follows that \( E \) has the structure of a commutative algebra object of \( L \mathcal{C} \), and therefore a commutative algebra object of \( \mathcal{C} \). To describe the situation more precisely, it is convenient to introduce a bit of terminology:

**Definition 4.8.2.8.** Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category. We will say that a commutative algebra object \( A \in \text{CAlg}(\mathcal{C}) \) is *idempotent* if the multiplication map \( A \otimes A \to A \) is an equivalence. Let \( \text{CAlg}^{\text{idem}}(\mathcal{C}) \) denote the full subcategory of \( \text{CAlg}(\mathcal{C}) \) spanned by the idempotent commutative algebra objects.
Note that if $A$ is a commutative algebra object of $\mathcal{C}$ with unit map $e : 1 \to A$, then the map $\text{id}_A \otimes e : A \to A \otimes A$ is a right inverse to the multiplication map $A \otimes A \to A$. It follows that $A$ is an idempotent commutative algebra object of $\mathcal{C}$ if and only if $e$ exhibits $A$ as an idempotent object of $\mathcal{C}$. In fact, we can be more precise:

**Proposition 4.8.2.9.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category with unit object $1$, which we regard as a trivial algebra object of $\mathcal{C}$. Then the functor

$$\theta : \text{CAlg}^{\text{idem}}(\mathcal{C}) \subseteq \text{CAlg}(\mathcal{C}) \simeq \text{CAlg}(\mathcal{C})_{1/} \to \mathcal{C}_{1/}$$

is fully faithful, and its essential image is the collection of maps $e : 1 \to E$ which exhibit $E$ as an idempotent object of $\mathcal{C}$.

**Proof.** The arguments sketched above show that $\theta$ is essentially surjective. We prove that $\theta$ is fully faithful. Let $A, A' \in \text{CAlg}(\mathcal{C})$ be idempotent algebras with units $e : 1 \to A$ and $e' : 1 \to A'$. It will suffice to show that if $\text{Map}_{\text{CAlg}}(A, A')$ is nonempty, then $\text{Map}_{\text{CAlg}}(A, A')$ and $\text{Map}_{\text{CAlg}(\mathcal{C})}(A, A')$ are both contractible. Assume therefore that $\text{Map}_{\text{CAlg}}(A, A')$ is nonempty, so that $e'$ factors as a composition $1 \xrightarrow{f} A \xrightarrow{\theta} A'$ for some morphism $f$ in $\mathcal{C}$. Note that $A$ and $A'$ are idempotent objects of $\mathcal{C}$; let $L$ and $L'$ denote the associated localization functors. Then $L'(e)$ exhibits $L'A$ as an idempotent object of $L'\mathcal{C}$, and $L'(e)$ has a left inverse. It follows that $L'(e)$ is an equivalence. Since $A'$ is $L$-local, we immediately deduce that $\text{Map}_{\text{CAlg}}(A, A') \simeq \text{Map}_{\text{CAlg}_{L/1}}(L'A, L'A')$ is contractible.

Note that $A$ can be identified with an initial object of the full subcategory $\text{CAlg}(L\mathcal{C}) \subseteq \text{CAlg}(\mathcal{C})$. To show that $\text{Map}_{\text{CAlg}(\mathcal{C})}(A, A')$ is contractible, it suffices to show that $A' \in L\mathcal{C}$. We have a commutative diagram

$$
\begin{array}{ccc}
A \otimes A' & \xrightarrow{e \otimes \text{id}_{A'}} & A' \\
\downarrow{f \otimes \text{id}_{A'}} & & \downarrow{e' \otimes \text{id}_{A'}} \\
A' & \rightarrow & A' \otimes A'
\end{array}
$$

Since the horizontal map is an equivalence, this diagram exhibits $A'$ as a retract of $A \otimes A'$. Since $A \otimes A'$ is $L$-local, we conclude that $A'$ is $L$-local. 

**Proposition 4.8.2.10.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category and let $A$ be an idempotent object of $\text{CAlg}(\mathcal{C})$. Let $L : \mathcal{C} \to \mathcal{C}$ be the associated localization functor (given by tensor product with $A$), so that $L\mathcal{C}$ inherits the structure of a symmetric monoidal $\infty$-category (Proposition 4.8.2.7). Then the forgetful functor $G : \text{Mod}_A(\mathcal{C})^\otimes \to \mathcal{C}^\otimes$ determines an equivalence of symmetric monoidal $\infty$-categories $\text{Mod}_A(\mathcal{C})^\otimes \to (L\mathcal{C})^\otimes$.

**Proof.** The forgetful functor $G$ admits a symmetric monoidal left adjoint $F : \mathcal{C}^\otimes \to \text{Mod}_A(\mathcal{C})^\otimes$, given by tensor product with $F$. Let $M \in \text{Mod}_A(\mathcal{C})$; we will abuse notation by identifying $M$ with its image in $\mathcal{C}$. The composition

$$M \simeq 1 \otimes M \to A \otimes M \to M$$

is homotopic to the identity, so that $M$ is a retract of $A \otimes M$ in $\mathcal{C}$ and therefore belongs to $L\mathcal{C}$. It follows that the counit map $F \circ G \to \text{id}$ is an equivalence of functors for $\text{Mod}_A(\mathcal{C})^\otimes$ to itself, so that $G$ determines an equivalence onto the full subcategory of $\mathcal{C}^\otimes$ spanned by those objects $X$ such that the unit map $X \to (G \circ F)(X)$ is an equivalence. Unwinding the definitions, we see that this subcategory coincides with $(L\mathcal{C})^\otimes$. 

We now specialize to the case where $\mathcal{C}$ is the $\infty$-category $\mathcal{P}^{hl}$ of presentable $\infty$-categories, endowed with the symmetric monoidal structure described in §4.8.1. The unit object of $\mathcal{P}^{hl}$ is the $\infty$-category of spaces. If $\mathcal{C}$ is presentable $\infty$-category with a distinguished object $C \in \mathcal{C}$, we will say that $(\mathcal{C}, C)$ is idempotent if there is a colimit-preserving functor $F : \mathcal{S} \to \mathcal{C}$ with $F(*) = C$ which exhibits $\mathcal{C}$ as an idempotent object of $\mathcal{P}^{hl}$. Note that in this case, the functor $F$ is well-defined up to a contractible space of choices (Theorem
T.5.1.5.6). It then follows from Proposition 4.8.2.9 that \( \mathcal{C} \) has the structure of a commutative algebra object of \( \Pr_1 \), and that \( F : S \to \mathcal{C} \) is the unit map for this algebra structure. In other words, there is a canonical symmetric monoidal structure on \( \mathcal{C} \) for which \( C \in \mathcal{C} \) is the unit object.

We now give some examples of idempotent objects of \( \Pr_1 \).

**Proposition 4.8.2.11.** Let \( S_* \) denote the \( \infty \)-category of pointed spaces, and let \( S^0 \) denote the 0-sphere (that is, a pointed space consisting of exactly two points). Then \((S_*, S^0)\) is idempotent. Moreover, the forgetful functor \( \text{Mod}_S : \Pr_1 \to \Pr_1 \) determines a fully faithful embedding, whose essential image is the full subcategory \( \Pr_{1,1}^S \subseteq \Pr_1 \) spanned by the pointed presentable \( \infty \)-categories.

**Lemma 4.8.2.12.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories, and assume that \( \mathcal{C} \) has an initial object. Let \( \text{Fun}'(\mathcal{C}, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) spanned by those functors which carry initial objects of \( \mathcal{C} \) to final objects of \( \mathcal{D} \), and define \( \text{Fun}'(\mathcal{C}, \mathcal{D}_*) \) similarly. Then the forgetful functor \( \theta : \text{Fun}'(\mathcal{C}, \mathcal{D}_*) \to \text{Fun}'(\mathcal{C}, \mathcal{D}) \) is a trivial fibration of simplicial sets.

**Remark 4.8.2.13.** If the \( \infty \)-category \( \mathcal{D} \) does not have a final object, then the conclusion of Lemma 4.8.2.12 is true but vacuous: both of the relevant \( \infty \)-categories of functors are empty.

**Proof.** We first observe that objects of \( \text{Fun}'(\mathcal{C}, \mathcal{D}_*) \) can be identified with maps \( F : \mathcal{C} \times \Delta^1 \to \mathcal{D} \) with the following properties:

1. For every initial object \( C \in \mathcal{C} \), \( F(C, 1) \) is a final object of \( \mathcal{D} \).
2. For every object \( C \in \mathcal{C} \), \( F(C, 0) \) is a final object of \( \mathcal{D} \).

Assume for the moment that (a) is satisfied, and let \( \mathcal{C}' \subseteq \mathcal{C} \times \Delta^1 \) be the full subcategory spanned by those objects \((C, i)\) for which either \( i = 1 \), or \( C \) is an initial object of \( \mathcal{C} \). We observe that (b) is equivalent to the following pair of conditions:

1. The functor \( F|\mathcal{C}' \) is a right Kan extension of \( F|\mathcal{C} \times \{1\} \).
2. The functor \( F \) is a left Kan extension of \( F|\mathcal{C}' \).

Let \( \mathcal{E} \) be the full subcategory of \( \text{Fun}(\mathcal{C} \times \Delta^1, \mathcal{D}) \) spanned by those functors which satisfy conditions (b') and (b''). Using Proposition T.4.3.2.15, we deduce that the projection \( \overline{\theta} : \mathcal{E} \to \text{Fun}(\mathcal{C} \times \{1\}, \mathcal{D}) \) is a trivial Kan fibration. Since \( \theta \) is a pullback of \( \overline{\theta} \), we conclude that \( \theta \) is a trivial Kan fibration.

**Proof of Proposition 4.8.2.11.** The object \( S^0 \in S_* \) corresponds to the colimit-preserving functor \( F : S \to S_* \) which assigns to each space \( X \in S \) the pointed space \( X_+ = X \coprod \{*\} \) obtained by adjoining to \( X \) a disjoint base point. According to Propositions 4.8.2.4 and 4.8.2.10, it will suffice to show the following:

1. For every presentable \( \infty \)-category \( \mathcal{E} \), the functor \( F \) induces a map \( F_\mathcal{E} : \mathcal{E} \simeq \mathcal{E} \otimes S \to \mathcal{E} \otimes S_* \) which exhibits \( \mathcal{E} \otimes S_* \) as a \( \Pr_{1,1}^S \)-localization of \( \mathcal{E} \).

In view of Example 4.8.1.20, it will suffice to show that if \( \mathcal{C} \) and \( \mathcal{D} \) are presentable \( \infty \)-categories such that \( \mathcal{D} \) is pointed, then the canonical map \( \text{Fun}^R(\mathcal{D}, \mathcal{C}_*) \to \text{Fun}^R(\mathcal{D}, \mathcal{C}) \) is an equivalence of \( \infty \)-categories (here \( \text{Fun}^R(\mathcal{D}, \mathcal{C}) \) denotes the full subcategory of \( \text{Fun}(\mathcal{D}, \mathcal{C}) \) spanned by those accessible functors which preserve small limits, and \( \text{Fun}^R(\mathcal{D}, \mathcal{C}_*) \) is defined similarly). This follows from Lemma 4.8.2.12, Proposition T.1.2.13.8, and Proposition T.4.4.2.9.

**Remark 4.8.2.14.** It follows from Proposition 4.8.2.11 that the \( \infty \)-category \( S_* \) of pointed spaces inherits a symmetric monoidal structure. This symmetric monoidal structure is uniquely determined by the requirements that the tensor product \( \otimes : S_* \times S_* \to S_* \) preserve colimits separately in each variable and that the unit object is given by \( S^0 \in S_* \) (Proposition 4.8.2.9). It follows that this tensor product is given by the classical *smash product* of pointed spaces: that is, it assigns to a pair of pointed spaces \( X \) and \( Y \) the space \( X \wedge Y \) obtained from \( X \times Y \) by collapsing the subspaces \( X \) and \( Y \) to the base point.
Proposition 4.8.2.15. Let \( n \geq -2 \) be an integer, and let \( \tau_{\leq n} \mathcal{S} \) denote the full subcategory of \( \mathcal{S} \) spanned by the \( n \)-truncated spaces. Then the pair \((\tau_{\leq n} \mathcal{S}, \ast)\) is idempotent (here \( \ast \in \mathcal{S} \) denotes the space consisting of a single point, which is automatically \( n \)-truncated). Moreover, the forgetful functor \( \text{Mod}_{\mathcal{S}}(\mathcal{P}r^L) \to \mathcal{P}r^L \) determines a fully faithful embedding, whose essential image is the full subcategory of \( \mathcal{X} \subseteq \mathcal{P}r^L \) spanned by the presentable \( \infty \)-categories which are equivalent to \((n+1)\)-categories (see Definition T.2.3.4.1).

Proof. The object \( \ast \in \tau_{\leq n} \mathcal{S} \) corresponds to the colimit-preserving functor \( \tau_{\leq n} : \mathcal{S} \to \tau_{\leq n} \mathcal{S} \) which assigns to each space \( X \in \mathcal{S} \) its \( n \)-truncation. According to Propositions 4.8.2.4 and 4.8.2.10, it will suffice to show the following:

\[ (*) \quad \text{For every presentable } \infty \text{-category } \mathcal{C}, \text{ the functor } \tau_{\leq n} \text{ induces a map } \theta : \mathcal{C} \simeq \mathcal{C} \otimes \mathcal{S} \to \mathcal{C} \otimes \tau_{\leq n} \mathcal{S} \text{ which exhibits } \mathcal{C} \otimes \tau_{\leq n} \mathcal{S} \text{ as a } \mathcal{X} \text{-localization of } \mathcal{C}. \]

Using Example 4.8.1.21, we are reduced to the following statement: if \( \mathcal{C} \) and \( \mathcal{D} \) are presentable \( \infty \)-categories such that \( \mathcal{D} \) is equivalent to an \((n+1)\)-category, then every \( F \in \text{Fun}^L(\mathcal{C}, \mathcal{D}) \) has a right adjoint \( G : \mathcal{D} \to \mathcal{C} \) which factors through \( \tau_{\leq n} \mathcal{C} \). This is immediate, since \( G \) is left exact and therefore carries objects of \( \mathcal{D} \) (which are automatically \( n \)-truncated by virtue of our assumption on \( \mathcal{D} \)) to \( n \)-truncated objects of \( \mathcal{C} \).

Remark 4.8.2.16. Proposition 4.8.2.15 implies that each \( \tau_{\leq n} \mathcal{S} \) is equipped with a symmetric monoidal structure, which is uniquely determined by the requirement that the tensor product \( \tau_{\leq n} \mathcal{S} \times \tau_{\leq n} \mathcal{S} \to \tau_{\leq n} \mathcal{S} \) preserve colimits separately in each variable, and that the object \( \ast \in \tau_{\leq n} \mathcal{S} \) be the unit object. It follows that this symmetric monoidal structure coincides with the Cartesian symmetric monoidal structure introduced in §2.4.1.

Remark 4.8.2.17. The proof of Proposition 4.8.2.15 shows that for any presentable \( \infty \)-category \( \mathcal{C} \) and any \( n \geq 0 \), the tensor product \( \mathcal{C} \otimes \tau_{\leq n} \mathcal{S} \) can be identified with the full subcategory \( \tau_{\leq n} \mathcal{C} \subseteq \mathcal{C} \) spanned by the \( n \)-truncated objects of \( \mathcal{C} \).

We now turn to the main case of interest.

Proposition 4.8.2.18. Let \( \text{Sp} \) denote the \( \infty \)-category of spectra, and let \( S \in \text{Sp} \) be the sphere spectrum. Then \( (\text{Sp}, S) \) is idempotent. Moreover, the forgetful functor \( \text{Mod}_{\text{Sp}}(\mathcal{P}r^L) \to \mathcal{P}r^L \) determines a fully faithful embedding whose essential image is the full subcategory \( \mathcal{P}r^L_{\ast \mathcal{S}} \subseteq \mathcal{P}r^L \) spanned by the stable presentable \( \infty \)-categories.

Proof. The object \( S \in \text{Sp} \) corresponds to the colimit-preserving functor \( \Sigma^\infty : \mathcal{S} \to \text{Sp} \). According to Propositions 4.8.2.4 and 4.8.2.10, it will suffice to show the following:

\[ (*) \quad \text{For every presentable } \infty \text{-category } \mathcal{C}, \text{ the functor } \Sigma^\infty \text{ induces a map } F : \mathcal{C} \simeq \mathcal{C} \otimes S \to \mathcal{C} \otimes \text{Sp} \text{ which exhibits } \mathcal{C} \otimes \text{Sp} \text{ as a } \mathcal{P}r^L_{\ast \mathcal{S}} \text{-localization of } \mathcal{C}. \]

This follows immediately from Example 4.8.1.22 and Corollary 1.4.4.5.

Corollary 4.8.2.19. There exists a symmetric monoidal structure on the \( \infty \)-category \( \text{Sp} \) such that \( S \in \text{Sp} \) is the unit object and the tensor product \( \otimes : \text{Sp} \times \text{Sp} \to \text{Sp} \) preserves small colimits separately in each variable. Moreover, if \( \mathcal{C}^\otimes \) is an arbitrary symmetric monoidal \( \infty \)-category such that \( \mathcal{C} \) is stable and presentable and the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves colimits separately in each variable, then there exists a symmetric monoidal functor \( \text{Sp}^\otimes \to \mathcal{C}^\otimes \) such that the underlying functor \( \text{Sp} \to \mathcal{C} \) preserves small colimits. Moreover, the collection of such functors is parameterized by a contractible Kan complex.

In other words, the \( \infty \)-category \( \text{Sp} \) admits a symmetric monoidal structure, which is uniquely characterized by the following properties:

\[ (a) \quad \text{The bifunctor } \otimes : \text{Sp} \times \text{Sp} \to \text{Sp} \text{ preserves small colimits separately in each variable.} \]

\[ (b) \quad \text{The unit object of } \text{Sp} \text{ is the sphere spectrum } S. \]
We will refer to this monoidal structure on $\text{Sp}$ as the smash product symmetric monoidal structure.

**Remark 4.8.2.20.** It follows from Proposition 4.8.2.18 that every stable presentable $\infty$-category $\mathcal{C}$ is canonically tensored over the symmetric monoidal $\infty$-category $\text{Sp}$.

**Warning 4.8.2.21.** Given a pair of objects $X,Y \in h\text{Sp}$, the smash product of $X$ and $Y$ is usually denoted by $X \wedge Y$. We will depart from this convention by writing instead $X \otimes Y$ for the smash product.

**Remark 4.8.2.22.** For any $\infty$-operad $\mathcal{O}^\otimes$, the symmetric monoidal structure on $\text{Sp}$ restricts to a $\mathcal{O}^\otimes$-monoidal structure on spectra. If $\mathcal{O}^\otimes$ is unital, then the proof of Corollary 4.8.2.19 shows that this $\mathcal{O}^\otimes$-monoidal structure is uniquely determined by the requirement that for each $X \in \mathcal{O}$, the corresponding unit object of $\text{Sp}$ is identified with the sphere spectrum.

Let $\text{Fun}_{\text{L}}(\text{Sp},\text{Sp})$ denote the full subcategory of $\text{Fun}(\text{Sp},\text{Sp})$ spanned by those functors which preserve small colimits. According to Corollary 1.4.4.6, evaluation at the sphere spectrum $S \in \text{Sp}$ induces an equivalence of $\infty$-categories $\text{Fun}(\text{Sp},\text{Sp}) \rightarrow \text{Sp}$, so that the smash product monoidal structure on $\text{Sp}$ determines a monoidal structure on $\text{Fun}(\text{Sp},\text{Sp})$. It follows from the above argument that this monoidal structure can be identified with the monoidal structure given by pointwise composition.

In Chapter 7, we will make an extensive study of the associative and commutative algebra objects of the $\infty$-category $\text{Sp}$.

### 4.8.3 Algebras and their Module Categories

Let $\mathcal{C}$ be a monoidal $\infty$-category and let $A \in \text{Alg}(\mathcal{C})$ be an algebra object of $\mathcal{C}$. In §4.3.2, we saw that the $\infty$-category $\text{RMod}_A(\mathcal{C})$ of right $A$-module objects of $\mathcal{C}$ is left-tensored over the $\infty$-category $\mathcal{C}$. In other words, we can identify $\text{RMod}_A(\mathcal{C})$ with a left module over $\mathcal{C}$ in the $\infty$-category $\text{Cat}_\infty$ (endowed with the Cartesian monoidal structure). Our goal in this section is to make a systematic study of this construction. We will proceed in several steps:

(i) We will begin by introducing an $\infty$-category $\text{Cat}^\otimes_{\text{Alg}}$ whose objects are pairs $(\mathcal{C}^\otimes,A)$, where $\mathcal{C}^\otimes$ is a monoidal $\infty$-category and $A$ is an algebra object of $\mathcal{C}^\otimes$. Roughly speaking, a morphism from $(\mathcal{C}^\otimes,A)$ to $(\mathcal{D}^\otimes,B)$ in $\text{Cat}^\otimes_{\text{Alg}}$ consists of a monoidal functor $F: \mathcal{C}^\otimes \rightarrow \mathcal{D}^\otimes$ together with a map of algebras $F(A) \rightarrow B$. For a more precise discussion, see Definition 4.8.3.7 below.

(ii) We will define another $\infty$-category $\text{Cat}_{\infty}^\otimes_{\text{Mod}}$, whose objects can be viewed as pairs $(\mathcal{C}^\otimes,M)$ where $\mathcal{C}^\otimes$ is a monoidal $\infty$-category and $M$ is an $\infty$-category left-tensored over $\mathcal{C}^\otimes$.

(iii) We will construct a functor $\Theta$ from a subcategory of $\text{Cat}^\otimes_{\text{Alg}}$ to $\text{Cat}^\otimes_{\text{Mod}}$. Informally, the functor $\Theta$ associates to every pair $(\mathcal{C}^\otimes,A)$ the $\infty$-category $\text{RMod}_A(\mathcal{C})$ of right $A$-module objects of $\mathcal{C}^\otimes$.

The relevant constructions are straightforward but somewhat tedious. The reader who does not wish to become burdened by technicalities is invited to proceed directly to §4.8.4 and §4.8.5, where we will undertake a deeper study of the functor $\Theta$.

We begin by recalling some terminology.

**Definition 4.8.3.1.** Let $S$ be a simplicial set and let $\mathcal{O}^\otimes$ be an $\infty$-operad. A coCartesian $S$-family of $\mathcal{O}$-monoidal $\infty$-categories is a coCartesian fibration $q: \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes \times S$ with the following property: for every vertex $s \in S$, the induced map of fibers $\mathcal{C}^\otimes_s = \mathcal{C}^\otimes \times_S \{s\} \rightarrow \mathcal{O}^\otimes$ is a coCartesian fibration of $\infty$-operads. In this case, we will say that $q$ exhibits $\mathcal{C}^\otimes$ as a coCartesian $S$-family of $\mathcal{O}$-monoidal $\infty$-categories.

In special case $\mathcal{O}^\otimes = \text{Ass}^\otimes$, we will say that $q$ is a coCartesian $S$-family of monoidal $\infty$-categories, or that $q$ exhibits $\mathcal{C}^\otimes$ as a coCartesian $S$-family of monoidal $\infty$-categories.

**Notation 4.8.3.2.** If $q: \mathcal{C}^\otimes \rightarrow \text{Ass}^\otimes \times S$ is a coCartesian $S$-family of monoidal $\infty$-categories, we let $\mathcal{C}$ denote the fiber product $\mathcal{C}^\otimes \times_S \{1\}$, so that $q$ induces a coCartesian fibration $\mathcal{C} \rightarrow S$. 

Example 4.8.3.3. Let $\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)$ denote the $\infty$-category of associative monoid objects of $\mathcal{Cat}_\infty$. There is a canonical map $\text{Ass}^\otimes \times \text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty) \to \mathcal{Cat}_\infty$, which classifies a coCartesian fibration $q : \text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty) \to \text{Ass}^\otimes \times \text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)$. The coCartesian fibration $q$ exhibits $\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)$ as a coCartesian $\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)$-family of monoidal $\infty$-categories. Moreover, this family of monoidal $\infty$-categories is universal in the following sense: for every simplicial set $S$, the construction $(\phi : S \to \text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)) \mapsto S \times_{\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)} \text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)$ establishes a bijection between the collection of equivalence classes of diagrams $S \to \text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)$ and the collection of equivalence classes of coCartesian $S$-families of monoidal $\infty$-categories $\mathcal{E}^\otimes \to \text{Ass}^\otimes \times S$ (with essentially small fibers).

Definition 4.8.3.4. Let $K$ and $S$ be simplicial sets. We will say that a coCartesian $S$-family of $\infty$-categories $q : \mathcal{E}^\otimes \to \text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty) \times S$ is compatible with $K$-indexed colimits if the following conditions are satisfied:

(i) For each vertex $s \in S$, the fiber $\mathcal{E}_s$ admits $K$-indexed colimits.

(ii) For each vertex $s \in S$, the tensor product functor $\mathcal{E}_s \times \mathcal{E}_s \to \mathcal{E}_s$ preserves $K$-indexed colimits separately in each variable.

(iii) For every edge $s \to t$ in $S$, the induced functor $\mathcal{E}_s \to \mathcal{E}_t$ preserves $K$-indexed colimits.

If $\mathcal{K}$ is a collection of simplicial sets, we will say that $q$ is compatible with $\mathcal{K}$-indexed colimits if it is compatible with $K$-indexed colimits for each $K \in \mathcal{K}$.

Notation 4.8.3.5. Let $\mathcal{K}$ be a collection of simplicial sets. Let $\text{Mon}_{K_{\text{Ass}}}(\mathcal{Cat}_\infty)$ denote the subcategory of $\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)$ whose objects are monoidal $\infty$-categories $\mathcal{E}^\otimes$ which are compatible with $\mathcal{K}$-indexed colimits and whose morphisms are monoidal functors $F : \mathcal{C}^\otimes \to \mathcal{D}^\otimes$ such that the underlying functor $\mathcal{C} \to \mathcal{D}$ preserves $\mathcal{K}$-indexed colimits. Let $\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$ denote the fiber product $\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty) \times_{\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty)} \text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$. The evident map $q : \text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty) \to \text{Ass}^\otimes \times \text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$ exhibits $\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$ as a coCartesian $\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$-family of monoidal $\infty$-categories which is compatible with $\mathcal{K}$-indexed colimits. Moreover, it is universal with respect to this property: for every simplicial set $S$, pullback along $q$ induces a bijection from equivalence classes of diagrams $S \to \text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$ and equivalence classes of coCartesian $S$-families of monoidal $\infty$-categories which are compatible with $\mathcal{K}$-indexed colimits.

Remark 4.8.3.6. Let $\mathcal{Cat}_\infty(\mathcal{K})$ be defined as in Definition 4.8.1.1, and endowed with the symmetric monoidal structure described in Corollary 4.8.1.4. For every set $\mathcal{K}$ of $\infty$-categories, the equivalence

$$\text{Mon}_{\text{Ass}}(\mathcal{Cat}_\infty) \simeq \text{Alg}(\mathcal{E}_\infty)$$

restricts to an equivalence $\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty) \simeq \text{Alg}(\mathcal{E}_\infty(\mathcal{K}))$.

Definition 4.8.3.7. We let $\mathcal{E}^\otimes_{\text{Alg}}$ denote the full subcategory of the fiber product

$$\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty) \times_{\text{Fun}_{\mathcal{K}_{\text{Ass}}}(\mathcal{E}^\otimes \times \mathcal{K}_{\text{Ass}}(\mathcal{Cat}_\infty))} \text{Fun}_{\mathcal{K}_{\text{Ass}}}(\mathcal{E}^\otimes, \text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty))$$

spanned by those pairs $(\mathcal{E}^\otimes, A)$, where $\mathcal{E}^\otimes \in \text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$ is a monoidal $\infty$-category and $A$ is an algebra object of the monoidal $\infty$-category $\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty) \times_{\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)} \mathcal{E}^\otimes \simeq \mathcal{E}^\otimes$. If $\mathcal{K}$ is a collection of simplicial sets, we let $\mathcal{E}^\otimes_{\text{Alg}}(\mathcal{K})$ denote the fiber product $\mathcal{E}^\otimes_{\text{Alg}} \times_{\text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)} \text{Mon}_{\mathcal{K}_{\text{Ass}}}(\mathcal{Cat}_\infty)$.

Remark 4.8.3.8. The $\infty$-category $\mathcal{E}_{\text{Alg}}(\mathcal{K})$ is characterized up to equivalence by the following universal property: for any simplicial set $S$, there is a bijection between equivalence classes of diagrams $S \to \mathcal{E}_{\text{Alg}}(\mathcal{K})$ and equivalence classes of diagrams

$$\begin{array}{ccc}
\mathcal{E}^\otimes & \xrightarrow{q} & \text{Ass}^\otimes \times S \\
A \downarrow & & \downarrow \text{id} \\
\text{Ass}^\otimes \times S & \xrightarrow{\text{id}} & \text{Ass}^\otimes \times S,
\end{array}$$
where \( q \) exhibits \( \mathcal{C}^\otimes \) as a coCartesian \( S \)-family of monoidal \( \infty \)-categories whose fibers are essentially small, \( q \) is compatible with \( \mathcal{K} \)-indexed colimits, and \( A \) is an \( S \)-family of associative algebra objects of \( \mathcal{C}^\otimes \).

**Definition 4.8.3.9.** If \( q : \mathcal{C}^\otimes \to \text{Ass}^\otimes \times S \) is a coCartesian \( S \)-family of monoidal \( \infty \)-categories, then we will say that a map \( p : \mathcal{M}^\otimes \to \mathcal{L}\mathcal{M}^\otimes \times S \) exhibits \( \mathcal{M}^\otimes \) as a coCartesian \( S \)-family of \( \infty \)-categories left-tensored over \( \mathcal{C}^\otimes \) if \( p \) is a coCartesian \( S \)-family of \( \mathcal{L}\mathcal{M} \)-operads (in the sense of Definition 5.3.1.19) and we are given an isomorphism \( \mathcal{C}^\otimes \simeq \mathcal{M}^\otimes \times _{\mathcal{L}\mathcal{M}^\otimes} \text{Ass}^\otimes \).

**Notation 4.8.3.10.** If \( \mathcal{M}^\otimes \to \mathcal{L}\mathcal{M}^\otimes \times S \) is as in Definition 4.8.3.9, we let \( \mathcal{M} \) denote the fiber product \( \mathcal{M}^\otimes \times _{\mathcal{L}\mathcal{M}^\otimes} \{m\} \).

**Notation 4.8.3.11.** Let \( \mathcal{C}^\otimes \to \text{Ass}^\otimes \times S \) be a coCartesian \( S \)-family of monoidal \( \infty \)-categories. We define a simplicial set \( \widetilde{\text{Alg}}(\mathcal{C}) \) equipped with a forgetful map \( \widetilde{\text{Alg}}(\mathcal{C}) \to S \) so that the following universal property is satisfied: for every map of simplicial sets \( K \to S \), there is a canonical bijection

\[
\text{Hom}_S(K, \widetilde{\text{Alg}}(\mathcal{C})) \simeq \text{Hom}_{\text{Ass}^\otimes \times S}(\text{Ass}^\otimes \times K, \mathcal{C}^\otimes).
\]

We let \( \text{Alg}(\mathcal{C}) \) denote the full simplicial subset of \( \widetilde{\text{Alg}}(\mathcal{C}) \) spanned by those vertices which correspond to algebra objects in the monoidal \( \infty \)-category \( \mathcal{C}^\otimes \), for some vertex \( s \in S \).

Suppose we are given a coCartesian \( S \)-family \( \mathcal{M}^\otimes \to \mathcal{L}\mathcal{M}^\otimes \times S \) of \( \infty \)-categories left-tensored over \( \mathcal{C}^\otimes \). We let \( \text{LMod}(\mathcal{M}) \) denote a simplicial set with a map \( \text{LMod}(\mathcal{M}) \to S \) having the following universal property: for every map of simplicial sets \( K \to S \), there is a canonical bijection

\[
\text{Hom}_S(K, \text{LMod}(\mathcal{M})) \simeq \text{Hom}_{\text{L}\mathcal{M}^\otimes \times S}(\text{L}\mathcal{M}^\otimes \times K, \mathcal{M}^\otimes).
\]

We let \( \text{LMod}(\mathcal{M}) \) denote the full simplicial subset of \( \widetilde{\text{LMod}}(\mathcal{M}) \) whose vertices are left module objects of \( \mathcal{M}^\otimes \), for some vertex \( s \in S \).

**Remark 4.8.3.12.** In the special case where \( S = \Delta^0 \), the terminology of Notation 4.8.3.11 agrees with that of Definitions 4.1.1.6 and 4.2.1.13.

The following result is an easy consequence of Proposition T.3.1.2.1:

**Lemma 4.8.3.13.** Let \( q : \mathcal{C}^\otimes \to \text{Ass}^\otimes \times S \) be a coCartesian \( S \)-family of monoidal \( \infty \)-categories, let \( p : \mathcal{M}^\otimes \to \mathcal{L}\mathcal{M}^\otimes \times S \) be a coCartesian \( S \)-family of \( \infty \)-categories left-tensored over \( \mathcal{C}^\otimes \). Then:

1. The map \( q' : \text{Alg}(\mathcal{C}) \to S \) is a coCartesian fibration of simplicial sets.
2. A morphism \( A \to A' \) in \( \text{Alg}(\mathcal{C}) \) is \( q' \)-coCartesian if and only if the underlying map \( A(\langle 1 \rangle) \to A'(\langle 1 \rangle) \) is a \( q \)-coCartesian morphism in \( \mathcal{C} \subseteq \mathcal{C}^\otimes \).
3. The map \( r : \text{LMod}(\mathcal{M}) \to S \) is a coCartesian fibration of simplicial sets.
4. A morphism \( M \to M' \) in \( \text{LMod}(\mathcal{M}) \) is \( r \)-coCartesian if and only if its image in \( \text{Alg}(\mathcal{C}) \) is \( q' \)-coCartesian, and the induced map \( M(m) \to M'(m) \) is a \( p \)-coCartesian morphism in \( \mathcal{M} \subseteq \mathcal{M}^\otimes \).

**Definition 4.8.3.14.** Let \( \mathcal{K} \) be a collection of simplicial sets, and let \( \mathcal{C}^\otimes \to \text{Ass}^\otimes \times \mathcal{K} \) be a coCartesian \( \mathcal{K} \)-family of monoidal \( \infty \)-categories which is compatible with \( \mathcal{K} \)-indexed colimits, and let \( \mathcal{M}^\otimes \to \mathcal{L}\mathcal{M}^\otimes \times \mathcal{K} \) be a coCartesian \( \mathcal{K} \)-family of \( \infty \)-categories left-tensored over \( \mathcal{C}^\otimes \). We will say that \( \mathcal{M}^\otimes \) is compatible with \( \mathcal{K} \)-indexed colimits if the following conditions are satisfied:

1. For every vertex \( s \in S \) and each \( K \in \mathcal{K} \), the \( \infty \)-category \( \mathcal{M}_s \) admits \( K \)-indexed colimits.
2. For every vertex \( s \in S \) and each \( K \in \mathcal{K} \), the action map \( \mathcal{C}_s \times \mathcal{M}_s \to \mathcal{M}_s \) preserves \( K \)-indexed colimits separately in each variable.
(iii) For every edge $s \to t$ in $S$ and each $K \in \mathcal{X}$, the induced functor $\mathcal{M}_s \to \mathcal{M}_t$ preserves $K$-indexed colimits.

**Lemma 4.8.3.15.** Let $p : \mathcal{C} \to \text{Ass} \times S$ be a coCartesian $S$-family of monoidal $\infty$-categories and let $q : \mathcal{M} \to \mathcal{L}\mathcal{M} \times S$ be a coCartesian $S$-family of $\infty$-categories left-tensored over $\mathcal{C}$. Assume that both $p$ and $q$ are compatible with $\text{N}(\Delta)^{op}$-indexed colimits. Then:

1. The forgetful functor $r : \text{LMod}(\mathcal{M}) \to \text{Alg}(\mathcal{C})$ is a coCartesian fibration of simplicial sets.

2. Let $f : M \to N$ be an edge of $\text{LMod}(\mathcal{M})$, lying over an edge $f_0 : A \to B$ in $\text{Alg}(\mathcal{C})$, which in turn lies over an edge $\alpha : s \to t$ in $S$. Then $f$ is $r$-coCartesian if and only if it induces an equivalence $B \otimes_A M \to N$ in the $\infty$-category $\text{LMod}(\mathcal{M})_t$, where $\alpha_1 : \text{Alg}(\mathcal{C})_s \to \text{Alg}(\mathcal{C})_t$ denotes the functor induced by $\alpha$.

**Proof.** Choose a vertex $M \in \text{LMod}(\mathcal{M})$ lying over $A \in \text{Alg}(\mathcal{C})$, and let $f_0 : A \to B$ be an edge of $\text{Alg}(\mathcal{C})$ lying over an edge $\alpha : s \to t$ in $S$. To prove (1), we will show that $f_0$ can be lifted to an $r$-coCartesian morphism of $\text{LMod}(\mathcal{M})$; assertion (2) will be a consequence of our construction. Let $r' : \text{Alg}(\mathcal{C}) \to S$ denote the canonical projection. Using Proposition 4.8.3.13, we can lift $\alpha$ to an $(r' \circ r)$-coCartesian morphism $f' : M \to M'$ in $\text{LMod}(\mathcal{M})$: let $f'_0 : A \to A'$ denote the image of $f'$ in $\text{Alg}(\mathcal{C})$. Lemma 4.8.3.13 guarantees that $f'_0$ is $r'$-coCartesian, so we can identify $A'$ with $\alpha_1 A$; moreover, there exists a 2-simplex $\sigma$ of $\text{Alg}(\mathcal{C})$ corresponding to a diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f_0} & B \\
\downarrow f'_0 & & \downarrow \sigma \\
A' & \xrightarrow{f''_0} & B
\end{array}
\]

We will prove that $f''_0$ can be lifted to an $r$-coCartesian morphism $f''_0$ of $\text{LMod}(\mathcal{M})$. Using the fact that $r$ is an inner fibration, it will follow that there is a composition $f = f'' \circ f'$ lifting $f_0$, which is also $r$-coCartesian by virtue of Proposition T.2.4.17. We may therefore replace $f_0$ by $f''_0$ and thereby reduce to the case where $s = t$ and the edge $\alpha$ is degenerate.

Proposition 4.6.2.17 shows that $f_0$ can be lifted to a locally $r$-coCartesian morphism $f : M \to B \otimes_A M$ in $\text{LMod}(\mathcal{M})_s$. Since the projection $r_s : \text{LMod}(\mathcal{M})_s \to \text{Alg}(\mathcal{C})_s$ is a Cartesian fibration (Corollary 4.2.3.2), we deduce that $f$ is $r_s$-coCartesian (Corollary T.5.2.2.4). To prove that $f$ is $r$-coCartesian, it will suffice to show that for every edge $\beta : s \to t$ in $S$, the image $\beta(f)$ is an $r_\beta$-coCartesian morphism of the fiber $\text{LMod}(\mathcal{M})_t$. Using the characterization of $r_\beta$-coCartesian morphisms supplied by Proposition 4.6.2.17, we see that this is equivalent to the requirement that the canonical map $\alpha_1(B) \otimes_{\alpha_1 A} \alpha_1 M \to \alpha_1(B \otimes_A M)$ is an equivalence in $\text{LMod}(\mathcal{M})_t$. This is clear, since the functor $\alpha_1$ preserves tensor products and geometric realizations of simplicial objects.

**Definition 4.8.3.16.** Let $p : \mathcal{C} \to \text{Ass} \times S$ be a coCartesian $S$-family of monoidal $\infty$-categories. An $S$-family of algebra objects of $\mathcal{C}$ is a section of the projection map $\text{Alg}(\mathcal{C}) \to S$.

If $q : \mathcal{M} \to \mathcal{L}\mathcal{M} \times S$ is a coCartesian $S$-family of $\infty$-categories left-tensored over $\mathcal{C}$ and $A$ is an $S$-family of algebra objects of $\mathcal{C}$, then we let $\text{LMod}_A(\mathcal{M})$ denote the fiber product $\text{LMod}(\mathcal{M}) \times_{\text{Alg}(\mathcal{C})} S$.

**Remark 4.8.3.17.** In the situation of Definition 4.8.3.16, if $p$ and $q$ are compatible with $\text{N}(\Delta)^{op}$-indexed colimits, then Lemma 4.8.3.15 implies that the projection map $\text{LMod}(\mathcal{M}) \to S$ is a coCartesian fibration of simplicial sets.

**Variant 4.8.3.18.** Let $p : \mathcal{C} \to \text{Ass} \times S$ be a coCartesian $S$-family of monoidal $\infty$-categories. We will say that an inner fibration $q : \mathcal{M} \to \mathcal{L}\mathcal{M} \times S$ is a locally coCartesian $S$-family of $\infty$-categories left-tensored over $\mathcal{C}$ if we are given an isomorphism $\mathcal{C} \cong \mathcal{C}$ and, for every edge $\Delta^1 \to S$, the induced map $q_{\Delta^1} : \mathcal{M} \times S \Delta^1 \to \mathcal{L}\mathcal{M} \times \Delta^1$ is a coCartesian $\Delta^1$-family of $\infty$-categories left-tensored over $\mathcal{C} \times S \Delta^1$. If $K$ is a simplicial set, we will say that $q$ is compatible with $K$-indexed colimits if each $q_{\Delta^1}$ is compatible with $K$-indexed colimits. If $p$ and $q$ are compatible with $\text{N}(\Delta)^{op}$-indexed colimits and $A$ is an $S$-family of...
algebra objects of $\mathcal{C}^\otimes$, then we define $\text{LMod}(\mathcal{M})$ as in Notation 4.8.3.11 and $\text{LMod}_A(\mathcal{M})$ as in Definition 4.8.3.16. It follows from Remark 4.8.3.17 that the map $\text{LMod}_A(\mathcal{M}) \to S$ is a locally coCartesian fibration of simplicial sets.

**Variant 4.8.3.19.** In the situation of Definition 4.8.3.9, there is an evident dual notion of a *locally coCartesian* $S$-family of $\infty$-categories $\mathcal{M}_{\infty}^\otimes \to \mathcal{K}_{\infty}^\otimes \times S$ right-tensored over $\mathcal{C}^\otimes$. Given an $S$-family of algebra objects $A$ of $\mathcal{C}^\otimes$, we can then define a locally coCartesian fibration $\text{RMod}_A(\mathcal{M}) \to S$ (provided that $\mathcal{C}^\otimes$ and $\mathcal{M}_{\infty}^\otimes$ are compatible with $N(\Delta)^{\text{op}}$-indexed colimits), whose fiber over a vertex $s \in S$ is the $\infty$-category of right $A$-module objects of the fiber $\mathcal{M}_s$.

We let $\text{Cat}_{\infty}^{\text{Mod}} = \text{Mon}_{\mathcal{M}}(\text{Cat}_{\infty})$ denote the $\infty$-category of $\mathcal{L}$-monoid objects of $\text{Cat}_{\infty}$. We will informally describe the objects of $\text{Cat}_{\infty}^{\text{Mod}}$ as pairs $(\mathcal{C}, \mathcal{M})$, where $\mathcal{C}$ is an $\infty$-category equipped with a monoidal structure and $\mathcal{M}$ is an $\infty$-category equipped with a left action of $\mathcal{C}$. If $\mathcal{K}$ is a collection of simplicial sets, we let $\text{Cat}_{\infty}^{\text{Mod}}(\mathcal{K})$ denote the subcategory of $\text{Cat}_{\infty}^{\text{Mod}}$ whose objects are diagrams where $\mathcal{C}$ and $\mathcal{M}$ admit $\mathcal{K}$-indexed colimits and the tensor product functors

$$\mathcal{C} \times \mathcal{C} \to \mathcal{C}, \quad \mathcal{C} \times \mathcal{M} \to \mathcal{M}$$

preserve $\mathcal{K}$-indexed colimits separately in each variable, and whose morphisms are maps $(\mathcal{C}, \mathcal{M}) \to (\mathcal{C}', \mathcal{M}')$ such that the underlying functors $\mathcal{C} \to \mathcal{C}'$, $\mathcal{M} \to \mathcal{M}'$ preserve $\mathcal{K}$-indexed colimits.

**Remark 4.8.3.20.** The $\infty$-category $\text{Cat}_{\infty}^{\text{Mod}}(\mathcal{K})$ is characterized by the following universal property: for every simplicial set $S$, there is a canonical bijection between equivalence classes of diagrams $\mathcal{M}_{\infty}^\otimes \to \mathcal{K}_{\infty}^\otimes \times S$ which exhibit $\mathcal{M}_{\infty}^\otimes$ as a coCartesian $S$-family of $\infty$-categories left-tensored over some coCartesian $S$-family of monoidal $\infty$-categories $\mathcal{C}_{\infty}^\otimes = \mathcal{M}_{\infty}^\otimes \times_{\mathcal{L} \mathcal{M}_{\infty}^\otimes} \text{Ass}_{\infty}^\otimes$ such that $\mathcal{C}_{\infty}^\otimes$ and $\mathcal{M}_{\infty}^\otimes$ are compatible with $\mathcal{K}$-indexed colimits.

We now sketch the construction of the functor $\Theta$.

**Construction 4.8.3.21.** Let $\mathbf{Pr} : \mathcal{L} \mathcal{M}_{\infty}^\otimes \times \mathcal{R} \mathcal{M}_{\infty}^\otimes \to \mathcal{B} \mathcal{M}_{\infty}^\otimes$ be defined as in Construction 4.3.2.1, and let $\mathbf{Pr}_0$ denote the composition of $\mathbf{Pr}$ with the forgetful functor $\mathcal{B} \mathcal{M}_{\infty}^\otimes \to \text{Ass}_{\infty}^\otimes$. If $\mathcal{C}_{\infty}^\otimes \to \text{Ass}_{\infty}^\otimes \times S$ is a coCartesian $S$-family of monoidal $\infty$-categories, we let $\mathcal{C}_{\infty}^\otimes$ denote the pullback $\mathcal{C}_{\infty}^\otimes \times_{\text{Ass}_{\infty}^\otimes} (\mathcal{L} \mathcal{M}_{\infty}^\otimes \times \mathcal{R} \mathcal{M}_{\infty}^\otimes)$, which we regard as a coCartesian $\mathcal{L} \mathcal{M}_{\infty}^\otimes \times \mathcal{S}$-family of $\mathcal{R} \mathcal{M}_{\infty}^\otimes$-monoidal $\infty$-categories; let $\mathcal{C}_{\mathcal{S}} = \mathcal{C}_{\infty}^\otimes \times_{\mathcal{R} \mathcal{M}_{\infty}^\otimes} \text{Ass}_{\infty}^\otimes$ be the underlying (\mathcal{L} \mathcal{M}_{\infty}^\otimes \times \mathcal{S})-family of monoidal $\infty$-categories.

Suppose that $A : S \to \text{Alg}(\mathcal{C})$ is an $S$-family of algebra objects of $\mathcal{C}_{\infty}^\otimes$. Then $A$ determines a $(\mathcal{L} \mathcal{M}_{\infty}^\otimes \times \mathcal{S})$-family of algebra objects of $\mathcal{C}_{\infty}^\otimes$, which we will denote by $\overline{A}$. We let $\text{RMod}_A(\mathcal{C})^\otimes$ denote the simplicial set $\text{RMod}_A(\mathcal{C})$ of Variant 4.8.3.19. If $\mathcal{C}_{\mathcal{S}} \to \text{Ass}_{\infty}^\otimes \times S$ is compatible with $N(\Delta)^{\text{op}}$-indexed colimits, then Lemma 4.8.3.15 implies that the map $\text{RMod}_A(\mathcal{C})^\otimes \to \mathcal{L} \mathcal{M}_{\infty}^\otimes \times S$ is a coCartesian $S$-family of $\mathcal{L} \mathcal{M}_{\infty}^\otimes$-monoidal $\infty$-categories. Let $\mathcal{C}_S^\otimes = \text{RMod}_A(\mathcal{C})^\otimes \times_{\mathcal{L} \mathcal{M}_{\infty}^\otimes} \text{Ass}_{\infty}^\otimes$ be the underlying $S$-family of monoidal $\infty$-categories. Using Propositions 4.3.2.6 and T.3.3.1.5, we deduce that the inclusion $\{m\} \to \mathcal{L} \mathcal{M}_{\infty}^\otimes$ induces a categorical equivalence $\mathcal{C}_S^\otimes \to \mathcal{C}_{\mathcal{S}}^\otimes$.

In the situation of Construction 4.8.3.21, if the original family $\mathcal{C}_{\mathcal{S}} \to \text{Ass}_{\infty}^\otimes \times S$ is compatible with $\mathcal{K}$-indexed colimits for some collection of simplicial sets $\mathcal{K}$ containing $N(\Delta)^{\text{op}}$, then $\text{RMod}_A(\mathcal{C})^\otimes \to \mathcal{L} \mathcal{M}_{\infty}^\otimes \times S$ is also compatible with $\mathcal{K}$-indexed colimits. We can summarize the situation as follows:

**Proposition 4.8.3.22.** Let $\mathcal{K}$ be a collection of simplicial sets which includes $N(\Delta)^{\text{op}}$, let $q : \mathcal{C}_{\mathcal{S}} \to \text{Ass}_{\infty}^\otimes \times S$ be a coCartesian $\mathcal{S}$-family of monoidal $\infty$-categories which is compatible with $\mathcal{K}$-indexed colimits, and let $A$ be an $S$-family of algebra objects of $\mathcal{C}_{\mathcal{S}}^\otimes$. Then the forgetful functor $p : \text{RMod}_A(\mathcal{C})^\otimes \to \mathcal{L} \mathcal{M}_{\infty}^\otimes \times S$ exhibits the coCartesian fibration $\text{RMod}_A(\mathcal{C}) \to S$ of Variant 4.8.3.19 as left-tensored over a coCartesian $\mathcal{S}$-family of monoidal $\infty$-categories $\mathcal{C}_{\mathcal{S}}^\otimes$ which is equivalent to $\mathcal{C}_{\mathcal{S}}^\otimes$. Moreover, $p$ is also compatible with $\mathcal{K}$-indexed colimits.

**Remark 4.8.3.23.** In the special case $S = \Delta^0$, Proposition 4.8.3.22 amounts to the fact that there is a natural action of the monoidal $\infty$-category $\mathcal{C}$ on $\text{RMod}_A(\mathcal{C})$, for each $A \in \text{Alg}(\mathcal{C})$. This statement was established in §4.3.2 (and does not require any assumptions on $\mathcal{C}$).
Constructions 4.8.3.24. Fix a collection of simplicial sets \( \mathcal{K} \) which includes \( N(\Delta)^{op} \). Let \( \mathcal{C}^\otimes \) denote the fiber product \( \mathcal{C}_{\mathcal{K}}^{\text{Alg}}(\mathcal{K}) \times_{\text{Mon}_{\text{Ass}}(\mathcal{C}^{\infty})} \text{Mon}_{\text{Ass}}^{\mathcal{K}}(\mathcal{C}^{\infty}) \), so that we have a coCartesian \( \mathcal{C}^{\text{Alg}}(\mathcal{K}) \)-family of monoidal \( \infty \)-categories \( \mathcal{C}^\otimes \rightarrow \mathcal{A}_{\mathcal{K}}^{\otimes} \times \mathcal{C}^{\text{Alg}}(\mathcal{K}) \). By construction, there is a canonical \( \mathcal{C}^{\text{Alg}}(\mathcal{K}) \)-family of algebra objects of \( \mathcal{C}^\otimes \), which we will denote by \( \mathcal{C}^{\text{Alg}}(\mathcal{K}) \rightarrow \mathcal{C}^{\text{Mod}}(\mathcal{K}) \). Note that the composite functor \( \mathcal{C}^{\text{Alg}}(\mathcal{K}) \rightarrow \mathcal{C}^{\text{Mod}}(\mathcal{K}) \rightarrow \text{Mon}_{\text{Ass}}^{\mathcal{K}}(\mathcal{C}^{\infty}) \) classifies the coCartesian \( \mathcal{C}^{\text{Alg}}(\mathcal{K}) \)-family of monoidal \( \infty \)-categories which is compatible with \( \mathcal{K} \)-indexed colimits. Remark 4.8.3.25 implies that this family is classified by a functor \( \Theta : \mathcal{C}^{\text{Alg}}(\mathcal{K}) \rightarrow \mathcal{C}^{\text{Mod}}(\mathcal{K}) \). More informally, we can describe the functor \( \Theta : \mathcal{C}^{\text{Alg}}(\mathcal{K}) \rightarrow \mathcal{C}^{\text{Mod}}(\mathcal{K}) \) which we will denote by \( \Theta \) as follows: to every object \( (\mathcal{C}^\otimes, A) \) of \( \mathcal{C}_{\mathcal{K}}^{\text{Alg}}(\mathcal{K}) \) (given by a monoidal \( \infty \)-category \( \mathcal{C}^\otimes \) and an algebra object \( A \in \text{Alg}(\mathcal{C}^\otimes) \)), it associates the \( \infty \)-category \( \text{RMod}_A(\mathcal{C}) \) of right \( A \)-module objects of \( \mathcal{C} \), viewed as an \( \infty \)-category left-tensored over \( \mathcal{C} \).

4.8.4 Properties of \( \text{RMod}_A(\mathcal{C}) \)

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category and let \( A \) be an algebra object of \( \mathcal{C} \). The \( \infty \)-category \( \text{RMod}_A(\mathcal{C}) \) of right \( A \)-module objects of \( \mathcal{C} \) admits a left action of the \( \infty \)-category \( \mathcal{C} \): informally speaking, if \( M \) is a right \( A \)-module and \( C \in \mathcal{C} \), then \( C \otimes M \) admits a right \( A \)-module structure given by the map

\[(C \otimes M) \otimes A \simeq C \otimes (M \otimes A) \rightarrow C \otimes M.\]

(for the formal construction, we refer the reader to §4.3.2). In this section, we will prove that (under some mild hypotheses) the \( \infty \)-category \( \text{RMod}_A(\mathcal{C}) \) enjoys two important features (which will be formulated more precisely below):

1. **If** \( N \) is an \( \infty \)-category left-tensored over \( \mathcal{C} \), then the \( \infty \)-category of \( \mathcal{C} \)-linear functors from \( \text{RMod}_A(\mathcal{C}) \) to \( N \) is equivalent to the \( \infty \)-category \( \text{LMod}_A(\mathcal{C}) \) of left \( A \)-module objects of \( N \) (Theorem 4.8.4.1).

2. **If** \( M \) is an \( \infty \)-category right-tensored over \( \mathcal{C} \), then the tensor product \( M \otimes_{\mathcal{C}} \text{RMod}_A(\mathcal{C}) \) is equivalent to the \( \infty \)-category \( \text{RMod}_A(\mathcal{M}) \) of right \( A \)-module objects of \( \mathcal{M} \) (Theorem 4.8.4.6).

We begin with a precise formulation of assertion (1):

**Theorem 4.8.4.1.** Let \( \mathcal{K} \) be a collection of simplicial sets which includes \( N(\Delta)^{op} \), let \( \mathcal{C}^\otimes \) be a monoidal \( \infty \)-category, and \( \mathcal{M} \) an \( \infty \)-category left-tensored over \( \mathcal{C} \). Assume that \( \mathcal{C} \) and \( \mathcal{M} \) admit \( \mathcal{K} \)-indexed colimits, and that the tensor product functors

\[\mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C} \quad \mathcal{C} \times \mathcal{M} \rightarrow \mathcal{M}\]

preserve \( \mathcal{K} \)-indexed colimits separately in each variable. Let \( A \) be an algebra object of \( \mathcal{C} \), and let \( \Theta \) denote the composition

\[
\text{LinFun}_{\mathcal{C}}^{\mathcal{K}}(\text{RMod}_A(\mathcal{C}), \mathcal{M}) \subseteq \text{LinFun}_{\mathcal{C}}(\text{RMod}_A(\mathcal{C}), \mathcal{M}) \xrightarrow{\Theta} \text{Fun}(\text{LMod}_A(\text{RMod}_A(\mathcal{C})), \text{LMod}_A(\mathcal{M})) \xrightarrow{\Theta'} \text{LMod}_A(\mathcal{M}),
\]
where $\theta'$ is the map described in Remark 4.6.2.9 and $\theta''$ is given by evaluation at the $A$-bimodule given by $A$. Then $\theta$ is an equivalence of $\infty$-categories.

A precise formulation of (B) requires more effort. In order to make sense of the relative tensor product $M \otimes_C RMod_A(\mathcal{E})$, we need to interpret each factor as an object of a relevant $\infty$-category. To this end, let us recall a bit of notation. Fix a collection of simplicial sets $\mathcal{M}$. We let $\mathcal{C}_{\infty}(\mathcal{K})$ be the subcategory of $\mathcal{C}_{\infty}$ whose objects are $\infty$-categories which admit $\mathcal{K}$-indexed colimits and whose morphisms are functors which preserve $\mathcal{K}$-indexed colimits, and regard $\mathcal{C}_{\infty}(\mathcal{K})$ as endowed with the (symmetric) monoidal structure described in §4.8.1 Some basic features of $\mathcal{C}_{\infty}(\mathcal{K})$ are summarized in the following result:

**Lemma 4.8.4.2.** Let $\mathcal{K}$ be a small collection of simplicial sets. Then the $\infty$-category $\mathcal{C}_{\infty}(\mathcal{K})$ is presentable, and the tensor product $\otimes: \mathcal{C}_{\infty}(\mathcal{K}) \times \mathcal{C}_{\infty}(\mathcal{K}) \to \mathcal{C}_{\infty}(\mathcal{K})$ preserves small colimits separately in each variable.

**Proof.** We first show that $\mathcal{C}_{\infty}(\mathcal{K})$ admits small colimits. Let $J$ be an $\infty$-category, and let $\chi: J \to \mathcal{C}_{\infty}(\mathcal{K})$ be a diagram. Let $\chi'$ denote the composition

$$J \xrightarrow{\chi} \mathcal{C}_{\infty}(\mathcal{K}) \subseteq \mathcal{C}_{\infty},$$

and let $\mathcal{C}$ be a colimit of the diagram $\chi'$ in $\mathcal{C}_{\infty}$. Let $\mathcal{R}$ denote the collection of all diagrams in $\mathcal{C}$ given by a composition

$$K^\triangleright \xrightarrow{\chi(J)} \mathcal{C},$$

where $K \in \mathcal{K}$ and $p$ is a colimit diagram. It follows from Proposition T.5.3.6.2 that there exists a functor $F: \mathcal{C} \to \mathcal{D}$ with the following properties:

(i) For every diagram $q: K^\triangleright \to \mathcal{C}$ belonging to $\mathcal{R}$, the composition $F \circ q$ is a colimit diagram.

(ii) The $\infty$-category $\mathcal{D}$ admits $\mathcal{K}$-indexed colimits.

(iii) For every $\infty$-category $\mathcal{E}$ which admits $\mathcal{K}$-indexed colimits, composition with $F$ induces an equivalence from the full subcategory of $\operatorname{Fun}(\mathcal{D}, \mathcal{E})$ spanned by those functors which preserve $\mathcal{K}$-indexed colimits to the full subcategory of $\operatorname{Fun}(\mathcal{C}, \mathcal{E})$ spanned by those functors such that the composition $\chi(J) \to \mathcal{C} \to \mathcal{E}$ preserves $\mathcal{K}$-indexed colimits for each $J \in J$.

The map $F$ allows us to promote $\mathcal{D}$ to an object of $\mathcal{D} = (\mathcal{C}_{\infty}(\mathcal{K}))_{\chi'}$. Using (i) and (ii), we deduce that $\mathcal{D}$ lies in the subcategory $\mathcal{C}_{\infty}(\mathcal{K})_{\chi'} \subseteq (\mathcal{C}_{\infty}(\mathcal{K}))_{\chi'}$, and (iii) that this lifting exhibits $\mathcal{D}$ as a colimit of the diagram $\chi$.

We next show that the tensor product $\otimes: \mathcal{C}_{\infty}(\mathcal{K}) \times \mathcal{C}_{\infty}(\mathcal{K}) \to \mathcal{C}_{\infty}(\mathcal{K})$ preserves small colimits separately in each variable. It will suffice to show that for every object $\mathcal{E} \in \mathcal{C}_{\infty}(\mathcal{K})$, the operation $\mathcal{D} \mapsto \mathcal{C} \otimes \mathcal{D}$ admits a right adjoint. This right adjoint is given by the formula $\mathcal{E} \mapsto \operatorname{Fun}^\triangleright(\mathcal{C}, \mathcal{E})$, where $\operatorname{Fun}^\triangleright(\mathcal{C}, \mathcal{E})$ denotes the full subcategory of $\operatorname{Fun}(\mathcal{C}, \mathcal{E})$ spanned by those functors which preserve $\mathcal{K}$-indexed colimits.

We now complete the proof by showing that $\mathcal{C}_{\infty}(\mathcal{K})$ is presentable. Fix an uncountable regular cardinal $\kappa$ so that $\mathcal{K}$ is $\kappa$-small and every simplicial set $K \in \mathcal{K}$ is $\kappa$-small. Choose another regular cardinal $\tau$ such that $\kappa < \tau$ and $\kappa < \tau$: that is, $\tau^\kappa_0 < \tau$ whenever $\tau_0 < \tau$ and $\kappa_0 < \kappa$. Let $\mathcal{C}_{\tau}(\mathcal{K})$ denote the full subcategory of $\mathcal{C}_{\infty}(\mathcal{K})$ spanned by those $\infty$-categories $\mathcal{E}$ which are $\tau$-small and admit $\mathcal{K}$-indexed colimits. Then $\mathcal{C}_{\tau}(\mathcal{K})$ is an essentially small $\infty$-category; it will therefore suffice to prove that every object $\mathcal{E} \in \mathcal{C}_{\tau}(\mathcal{K})$ is the colimit (in $\mathcal{C}_{\infty}(\mathcal{K})$) of a diagram taking values in $\mathcal{C}_{\tau}(\mathcal{K})$.

Let $A$ be the collection of all simplicial subsets $\mathcal{E}_0 \subseteq \mathcal{E}$ with the following properties:

(a) The simplicial set $\mathcal{E}_0$ is an $\infty$-category.

(b) The $\infty$-category $\mathcal{E}_0$ admits $\mathcal{K}$-indexed colimits.

(c) The inclusion $\mathcal{E}_0 \hookrightarrow \mathcal{E}$ preserves $\mathcal{K}$-indexed colimits.
(d) The simplicial set $\mathcal{C}_0$ is $\tau$-small.

Our proof rests on the following claim:

(*) For every $\tau$-small simplicial subset $\mathcal{C}_0 \subseteq \mathcal{C}$, there exists a $\tau$-small simplicial subset $\mathcal{C}_0' \subseteq \mathcal{C}$ which contains $\mathcal{C}_0$ and belongs to $A$.

Let us regard the set $A$ as partially ordered with respect to inclusions, and we have an evident functor $\rho : A \to \text{Set}_\Delta$. From assertion (\*), it follows that $A$ is filtered (in fact, $\tau$-filtered) and that $\mathcal{C}$ is the colimit of the diagram $\rho$ (in the ordinary category $\text{Set}_\Delta$). Since the collection of categorical equivalences in $\text{Set}_\Delta$ is stable under filtered colimits, we deduce that $\mathcal{C}$ is the homotopy colimit of the diagram $\rho$ (with respect to the Joyal model structure), so that $\mathcal{C}$ is the colimit of the induced diagram $N(\rho) : N(A) \to \text{Cat}_\infty$ (Theorem T.4.2.4.1). Requirement (c) guarantees that every inclusion $\mathcal{C}_0 \subseteq \mathcal{C}_1$ between elements of $A$ is a functor which preserves $\mathcal{K}$-indexed colimits, so that $N(\rho)$ factors through $\text{Cat}_\infty(\mathcal{K})$. We claim that $\mathcal{C}$ is a colimit of the diagram $N(\rho)$ in the $\infty$-category $\text{Cat}_\infty(\mathcal{K})$. Unwinding the definitions, this amounts to the following assertion: for every $\infty$-category $\mathcal{E}$ which admits $\mathcal{K}$-indexed colimits, a functor $F : \mathcal{E} \to \mathcal{C}$ preserves $\mathcal{K}$-indexed colimits if and only if $F|\mathcal{C}_0$ preserves $\mathcal{K}$-indexed colimits for each $\mathcal{C}_0 \in A$. The “only if” direction is obvious.

To prove the converse, choose $K \in \mathcal{K}$ and a colimit diagram $p : K^\circ \to \mathcal{C}$. The image of $p$ is $\tau$-small, so that (\*) guarantees that $p$ factors through $\mathcal{C}_0$ for some $\mathcal{C}_0 \in A$. Requirement (c) guarantees that $p$ is also a colimit diagram in $\mathcal{C}_0$, so that $F \circ p$ is a colimit diagram provided that $F|\mathcal{C}_0$ preserves $\mathcal{K}$-indexed colimits.

It remains only to prove assertion (\*). Fix a $\tau$-small subset $\mathcal{C}_0 \subseteq \mathcal{C}$. We define a transfinite sequence of $\tau$-small simplicial subsets $\{\mathcal{C}_0 \subseteq \mathcal{C}\}_{\alpha < \kappa}$. If $\alpha$ is a nonzero limit ordinal, we take $\mathcal{C}_\alpha = \bigcup_{\beta < \alpha} \mathcal{C}_\beta$. If $\alpha = \beta + 1$, we define $\mathcal{C}_\alpha$ to be any $\tau$-small simplicial subset of $\mathcal{C}$ with the following properties:

- Every map $\Delta_i^n \to \mathcal{C}_\beta$ for $0 < i < n$ extends to an $n$-simplex of $\mathcal{C}_\alpha$.

- For each $K \in \mathcal{K}$ and each map $q : K \to \mathcal{C}_\beta$, there exists an extension $\overline{q} : K^\circ \to \mathcal{C}_\alpha$ which is a colimit diagram in $\mathcal{C}$.

- Given $n > 0$ and a map $f : K \times \partial \Delta^n \to \mathcal{C}_\beta$ such that the restriction $f|K \times \{0\}$ is a colimit diagram in $\mathcal{C}$, there exists a map $\overline{f} : K \times \Delta^n \to \mathcal{C}_\alpha$ extending $f$.

Our assumption that $\kappa \ll \tau$ guarantees that we can satisfy these conditions by adjoining a $\tau$-small set of simplices to $\mathcal{C}_\beta$. Let $\mathcal{C}_0' = \bigcup_{\alpha < \kappa} \mathcal{C}_\alpha$. Then $\mathcal{C}_0'$ contains $\mathcal{C}_0$, and belongs to $A$ as desired.

Now suppose that $\mathcal{C}^\otimes$ is a monoidal $\infty$-category, that $\mathcal{M}$ is an $\infty$-category right-tensored over $\mathcal{C}$, and that $\mathcal{N}$ is an $\infty$-category left-tensored over $\mathcal{C}$. Fixing a collection of simplicial sets $\mathcal{K}$, we further assume that $\mathcal{C}$, $\mathcal{M}$, and $\mathcal{N}$ admit $\mathcal{K}$-indexed colimits, and that the tensor product functors

$$
\mathcal{M} \times \mathcal{C} \to \mathcal{M} \quad \mathcal{C} \times \mathcal{C} \to \mathcal{C} \quad \mathcal{C} \times \mathcal{N} \to \mathcal{N}
$$

preserve $\mathcal{K}$-indexed colimits separately in each variable. We can identify $\mathcal{C}^\otimes$ with an associative algebra object of $\text{Cat}_\infty(\mathcal{K})$, and the $\infty$-categories $\mathcal{M}$ and $\mathcal{N}$ with right and left modules over this associative algebra, respectively (Remark 2.4.2.6). Consequently, the relative tensor product $\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ can be defined using the constructions of §4.4.2. This tensor product is given as the geometric realization (in $\text{Cat}_\infty(\mathcal{K})$) of the simplicial object $\text{BarC}(\mathcal{M}, \mathcal{N})_*$ of Construction 4.4.2.7. The bar construction $\text{BarC}(\mathcal{M}, \mathcal{N})_*$ is given informally by the formula $[n] \mapsto \mathcal{M} \otimes \mathcal{C}^{\otimes n} \otimes \mathcal{N}$, where the tensor product is formed in the $\infty$-category $\text{Cat}_\infty(\mathcal{K})$. Consequently, this bar construction is dependent on the choice of the collection $\mathcal{K}$. To emphasize this dependence, we will denote $\text{BarC}(\mathcal{M}, \mathcal{N})_*$ by $\text{BarC}^K(\mathcal{M}, \mathcal{N})_*$. If $\mathcal{K}' \subseteq \mathcal{K}$, then we have a forgetful functor $\text{Cat}_\infty(\mathcal{K}) \to \text{Cat}_\infty(\mathcal{K}')$ which is lax symmetric monoidal, and induces a natural transformation $\text{BarC}^K(\mathcal{M}, \mathcal{N})_* \to \text{BarC}^{K'}(\mathcal{M}, \mathcal{N})$. In particular, we have a map $\theta : \text{BarC}^K(\mathcal{M}, \mathcal{N})_* \to \text{BarC}^K(\mathcal{M}, \mathcal{N})$. The map $\theta$ is characterized by the following universal property:
For each $n \geq 0$ and every $\infty$-category $\mathcal{E}$ which admits $\mathcal{K}$-indexed colimits, composition with $\theta$ induces an equivalence from the full subcategory of $\text{Fun}(\text{Bar}_\theta^\infty(\mathcal{M}, \mathcal{N}), \mathcal{E})$ spanned by those functors which preserve $\mathcal{K}$-indexed colimits to the full subcategory of $\text{Fun}(\text{Bar}_\theta^\infty(\mathcal{M}, \mathcal{N}), \mathcal{E}) \simeq \text{Fun}(\mathcal{M} \times \mathcal{E}^\otimes \times \mathcal{N}, \mathcal{E})$ spanned by those functors which preserve $\mathcal{K}$-indexed colimits separately in each variable.

We can identify $\text{Bar}_\theta^0(\mathcal{M}, \mathcal{N}) \bullet$ with a simplicial object $\chi : \mathcal{N}(\Delta)^{\text{op}} \to \mathcal{E}_{\infty}$. Let $\mathcal{E}^\otimes$, and $\mathcal{N}^\otimes$ be defined as in Notation 4.2.2.16 and define $\mathcal{M}^\otimes$ similarly. Unwinding the definitions, we see that $\chi$ classifies the coCartesian fibration $q : \mathcal{M}^\otimes \times_{\mathcal{E}^\otimes} \mathcal{N}^\otimes \to \mathcal{N}(\Delta)^{\text{op}}$. Proposition T.3.3.4.2 allows us to identify the geometric realization $|\text{Bar}_\theta^\infty(\mathcal{M}, \mathcal{N}) \bullet|$ with the $\infty$-category obtained from $\mathcal{M}^\otimes \times_{\mathcal{E}^\otimes} \mathcal{N}^\otimes$ obtained by inverting all of the $q$-coCartesian morphisms. Combining this observation with $(*)$, we obtain the following concrete description of the relative tensor product in $\mathcal{E}_{\infty}$.

**Lemma 4.8.4.3.** Let $\mathcal{K}$ be a small collection of simplicial sets and let $\mathcal{M}^\otimes \to \mathcal{E}^\otimes \leftarrow \mathcal{N}^\otimes$ be as above. For every $\infty$-category $\mathcal{E}$ which admits $\mathcal{K}$-indexed colimits, the natural transformation $\text{Bar}_\theta^0(\mathcal{M}, \mathcal{N}) \to \text{Bar}_\theta^\infty(\mathcal{M}, \mathcal{N}) \bullet$ induces an equivalence of $\infty$-categories from the full subcategory of $\text{Fun}(\mathcal{M} \otimes \mathcal{N}, \mathcal{E})$ spanned by those functors which preserve $\mathcal{K}$-indexed colimits to the full subcategory of $\text{Fun}(\mathcal{M}^\otimes \times_{\mathcal{E}^\otimes} \mathcal{N}^\otimes, \mathcal{E})$ spanned by those functors $\mathcal{F}$ with the following properties:

(i) The functor $\mathcal{F}$ carries $q$-coCartesian morphisms to equivalences in $\mathcal{E}$, where $q : \mathcal{M}^\otimes \times_{\mathcal{E}^\otimes} \mathcal{N}^\otimes \to \mathcal{N}(\Delta)^{\text{op}}$ denotes the canonical projection.

(ii) For each $n \geq 0$, the functor $\mathcal{M} \times \mathcal{E}^n \times \mathcal{N} \simeq q^{-1}\{[n]\} \to \mathcal{E}$ preserves $\mathcal{K}$-indexed colimits separately in each variable.

Our next goal is to apply Lemma 4.8.4.3 to construct a canonical map $\mathcal{M} \otimes_{\mathcal{E}} \text{RM}_{\mathcal{A}}(\mathcal{E}) \to \text{RM}_{\mathcal{A}}(\mathcal{M})$.

**Construction 4.8.4.4.** Let $\text{Cut} : \mathcal{N}(\Delta)^{\text{op}} \to \text{Ass}^\otimes \subseteq \text{RM}^\otimes$ be as in Construction 4.1.2.5, and let $\text{RCut} : \mathcal{N}(\Delta)^{\text{op}} \to \mathcal{M}^\otimes$ be the functor given by the the composition

$$\mathcal{N}(\Delta)^{\text{op}} \xrightarrow{\text{r}} \mathcal{N}(\Delta)^{\text{op}} \xrightarrow{\text{LCut}} \mathcal{LM}^\otimes \xrightarrow{\text{r}'} \mathcal{RM}^\otimes,$$

where $\text{r}$ and $\text{r}'$ are the isomorphisms given by order-reversal and LCut is the functor described in Construction 4.2.2.6.

We have a commutative diagram $\sigma$:

$$\begin{array}{ccc}
F_- & \leftarrow & F \\
\downarrow & & \downarrow \\
F' & \xrightarrow{\text{r}'} & F' \\
\downarrow & & \downarrow \\
F_+ & \leftarrow & F_+
\end{array}$$

in the $\infty$-category $\text{Fun}(\mathcal{N}(\Delta)^{\text{op}} \times \mathcal{N}(\Delta)^{\text{op}}, \mathcal{RM}^\otimes)$, where

$$F_-([m], [n]) = \text{RCut}([m]) \quad F([m], [n]) = \text{RCut}([m] \star [n]) \quad F_+([m], [n]) = \text{RCut}([n])$$

$$F'([m], [n]) = \text{Cut}([m]) \quad F'([m], [n]) = \text{Cut}([m] \star [n]) \quad F'_+([m], [n]) = \text{Cut}([n]).$$

The vertical maps in this diagram are induced by the natural transformation $\text{RCut} \to \text{Cut}$ described in Remark 4.2.2.8, and the horizontal maps by the inclusions $[m] \hookrightarrow [m] \star [n] \hookrightarrow [n]$.

Let $\rho : \mathcal{G}^\otimes \to \text{Ass}^\otimes$ be a monoidal $\infty$-category, and let $q : \mathcal{M}^\otimes \to \mathcal{RM}^\otimes$ be an $\infty$-category right-tensored over $\mathcal{E}^\otimes$. We let $\mathcal{G}'$ denote the full subcategory of $\text{Fun}(\mathcal{N}(\Delta)^{\text{op}}, \mathcal{E})$ spanned by those functors which carry each morphism in $\mathcal{N}(\Delta)^{\text{op}}$ to an equivalence, and let $\mathcal{M}' \subseteq \text{Fun}(\mathcal{N}(\Delta)^{\text{op}}, \mathcal{M})$ be defined similarly (since $\mathcal{N}(\Delta)^{\text{op}}$ is weakly contractible, the diagonal embeddings $\mathcal{E} \to \mathcal{E}'$ and $\mathcal{M} \to \mathcal{M}'$ are categorical equivalences). We
regard $\mathcal{C}'$ as a monoidal $\infty$-category and $\mathcal{M}'$ as an $\infty$-category right-tensored over $\mathcal{C}'$ (see Remark 2.1.3.4). Let $\mathcal{C}'^\otimes = \mathcal{C}' \times_{\mathcal{A}_{\mathcal{M}}^\otimes} \mathcal{N}(\Delta)^{op}$, let $\mathcal{M}'^\otimes$ be defined as in Notation 4.2.2.16 (suitably modified for purposes of discussing right actions, rather than left actions).

Fix an algebra object $A \in \text{Alg}(\mathcal{C})$ and regard $\text{RMod}_A(\mathcal{C})$ as an $\infty$-category left-tensored over $\mathcal{C}'$ as in §4.3.2. Let $\mathcal{X} = \mathcal{M}'^\otimes \times_{\mathcal{C}'^\otimes} \text{RMod}_A(\mathcal{C})$. We will lift $\sigma$ to a commutative diagram

$$
\begin{array}{ccc}
\mathcal{F}^- & \longrightarrow & \mathcal{F} \\
\downarrow & & \downarrow \\
\mathcal{F}'^- & \longrightarrow & \mathcal{F}'
\end{array}
$$

of functors from $\mathcal{X} \times \mathcal{N}(\Delta)^{op}$ to $\mathcal{M}^\otimes$ as follows:

(a) Let $\mathcal{F}'^-$ be the composition

$$
\mathcal{X} \times \mathcal{N}(\Delta)^{op} \to \mathcal{C}'^\otimes \times \mathcal{N}(\Delta)^{op} \to \mathcal{C} \subseteq \mathcal{M}^\otimes.
$$

(b) Let $\alpha'$ denote the composition $\mathcal{M}^\otimes \to \mathcal{C}'^\otimes \to \mathcal{C} \subseteq \mathcal{M}^\otimes$. By construction, $\mathcal{M}^\otimes$ is equipped with another functor $\alpha : \mathcal{M}^\otimes \to \mathcal{M}^\otimes$ and a natural transformation $\alpha \to \alpha'$. Composing $\alpha$ with the forgetful functor $\mathcal{X} \times \mathcal{N}(\Delta)^{op} \to \mathcal{M}^\otimes \times \mathcal{N}(\Delta)^{op}$ and the evaluation functor $\mathcal{M}^\otimes \times \mathcal{N}(\Delta)^{op} \to \mathcal{M}^\otimes$ we obtain a functor $\mathcal{F}_-$ equipped with a natural transformation $\mathcal{F}_- \to \mathcal{F}'_-$. 

(c) The functor $\mathcal{F}'$ is given by the composition

$$
\begin{array}{ccc}
\mathcal{X} \times \mathcal{N}(\Delta)^{op} & \longrightarrow & \text{RMod}_A(\mathcal{C})^\otimes \times \mathcal{N}(\Delta)^{op} \\
& & \to \text{Fun}(\mathcal{X}^\otimes, \mathcal{C}) \times \mathcal{N}(\Delta)^{op} \\
& & \overset{\text{RCut}}{\longrightarrow} \text{Fun}(\mathcal{N}(\Delta)^{op}, \mathcal{C}) \times \mathcal{N}(\Delta)^{op} \\
& & \subseteq \mathcal{M}^\otimes.
\end{array}
$$

Note that the inert natural transformation $\text{RCut} \to \text{Cut}$ induces a map of functors $\mathcal{F}' \to \mathcal{F}'_-$. 

(d) Using the assumption that $q$ is a fibration of $\infty$-operads, we can choose a functor $\mathcal{F}$ compatible with $F$, so that the diagram

$$
\begin{array}{ccc}
\mathcal{F}_- & \longrightarrow & \mathcal{F} \\
\downarrow & & \downarrow \\
\mathcal{F}'_- & \longrightarrow & \mathcal{F}'
\end{array}
$$

is a $q$-limit square (when evaluated at any object of $\mathcal{X} \times \mathcal{N}(\Delta)^{op}$).

(e) Let $\mathcal{F}'_+$ be the functor given by

$$
\mathcal{X} \times \mathcal{N}(\Delta)^{op} \to \mathcal{N}(\Delta)^{op} \overset{\text{Cut}}{\longrightarrow} \mathcal{A}_{\mathcal{M}}^\otimes \overset{A}{\longrightarrow} \mathcal{C} \subseteq \mathcal{M}^\otimes.
$$

The construction of $\text{RMod}_A(\mathcal{M})^\otimes$ guarantees a natural transformation of functors $\mathcal{F}' \to \mathcal{F}'_+$. 

(f) Since $q$ is a coCartesian fibration, we can choose a $q$-coCartesian natural transformation $\beta : \mathcal{F} \to \mathcal{F}_+$ covering the natural transformation $F \to F_+$. Since $\beta$ is $q$-coCartesian, there is an essentially unique
From this description, we see that $\Psi$ satisfies the requirements of Lemma 4.8.4.3. Let $K[\Delta] \to M^\otimes$. In the situation of Construction 4.8.4.4, we can think of an object of $\mathcal{X}$ as $\Psi$ lying over $[\Delta]$ as a finite sequence $(M, C_1, \ldots, C_n, N)$, where $M \in \mathcal{M}$, each $C_i \in \mathcal{C}$, and $N$ is a right $A$-module object of $\mathcal{E}$. The functor $\Psi$ is given informally by the formula $(M, C_1, \ldots, C_n, N) \mapsto M \otimes C_1 \otimes \cdots \otimes C_n \otimes N$. From this description, we see that $\Psi$ satisfies the requirements of Lemma 4.8.4.3. Let $\mathcal{X}$ be a collection of simplicial sets such that $\mathcal{E}$ and $M$ admit $\mathcal{X}$-indexed colimits, and that the tensor product functors

$$\mathcal{E} \times \mathcal{E} \to \mathcal{E}, \quad M \times \mathcal{E} \to \mathcal{M}$$

preserve $\mathcal{X}$-indexed colimits separately in each variable. Then $\Psi$ determines a functor $\Phi : M \otimes_C \text{RMod}_A(\mathcal{E}) \to \text{RMod}_A(M)$, which is well-defined up to equivalence.

We can now formulate (B) as follows:

**Theorem 4.8.4.6.** Let $\mathcal{X}$ be a small collection of simplicial sets which includes $N(\Delta)^{op}$, let $\mathcal{E}^\otimes$ be a monoidal $\infty$-category, let $M^\otimes \to \mathcal{E}^\otimes$ be an $\infty$-category right-tensored over $\mathcal{E}$, and let $A \in \text{Alg}(\mathcal{E})$ be an algebra object of $\mathcal{E}$. Suppose that the $\infty$-categories $\mathcal{E}$ and $M$ admit $\mathcal{X}$-indexed colimits, and the tensor product functors

$$\mathcal{E} \times \mathcal{E} \to \mathcal{E}, \quad M \times \mathcal{E} \to \mathcal{M}$$

preserve $\mathcal{X}$-indexed colimits separately in each variable. Then the above construction yields an equivalence of $\infty$-categories $M \otimes_C \text{RMod}_A(\mathcal{E}) \to \text{RMod}_A(M)$, where the tensor product is taken in $\mathcal{C}_{\text{at} \infty}(\mathcal{X})$.

**Remark 4.8.4.7.** In the formulation of Theorems 4.8.4.6 and 4.8.4.1, the $\infty$-categories $\text{RMod}_A(M)$ and $\text{LMod}_A(M)$ do not depend on the class of simplicial sets $\mathcal{X}$. It follows that the $\infty$-categories $M \otimes_C \text{RMod}_A(\mathcal{E})$ and $\text{LinFun}^X(\text{RMod}_A(\mathcal{E}), M)$ do not depend on $\mathcal{X}$, provided that $\mathcal{X}$ contains $N(\Delta)^{op}$.

**Remark 4.8.4.8.** Let $\mathcal{X}$ be a collection of simplicial sets which includes $N(\Delta)^{op}$ and regard $\mathcal{C}_{\text{at} \infty}(\mathcal{X})$ be the symmetric monoidal $\infty$-category as in Corollary 4.8.1.4. Let $\mathcal{E}$ be a monoidal $\infty$-category which admits $\mathcal{X}$-indexed colimits, such that the tensor product $\otimes : \mathcal{E} \times \mathcal{E} \to \mathcal{E}$ preserves $\mathcal{X}$-indexed colimits separately in each variable. Then we can regard $\mathcal{E}$ as an algebra object of $\mathcal{C}_{\text{at} \infty}(\mathcal{X})$. If $A \in \text{Alg}(\mathcal{E})$, then we regard $\text{LMod}_A(\mathcal{E})$ and $\text{RMod}_A(\mathcal{E})$ as right and left modules over $\mathcal{E}$ (in $\mathcal{C}_{\text{at} \infty}(\mathcal{X})$), respectively. Using Theorem 4.8.4.6, we can identify the tensor product $\text{RMod}_A(\mathcal{E}) \otimes_C \text{RMod}_A(\mathcal{E})$ with the $\infty$-category $\text{RMod}_A(\text{RMod}_A(\mathcal{E})) \simeq \text{A}, \text{BMod}_A(\mathcal{E})$. Regarding $A$ as a bimodule over itself, we obtain an object $A \text{A}_A \in \text{A}, \text{BMod}_A(\mathcal{E})$, which classifies a functor

$$S(\mathcal{X}) \to \text{LMod}_A(\mathcal{E}) \otimes_C \text{RMod}_A(\mathcal{E})$$

Here $S(\mathcal{X})$ denotes the unit object of $\mathcal{C}_{\text{at} \infty}(\mathcal{X})$ (see Notation 4.8.5.2). We claim that $c$ exhibits $\text{LMod}_A(\mathcal{E}) \in \text{RMod}_C(\mathcal{C}_{\text{at} \infty}(\mathcal{X}))$ as the left dual of $\text{RMod}_A(\mathcal{E}) \in \text{LMod}_C(\mathcal{C}_{\text{at} \infty}(\mathcal{X}))$. To prove this, it suffices to verify condition (a) of Proposition 4.6.2.18: that is, we must show that if $D \in \mathcal{C}_{\text{at} \infty}(\mathcal{X})$ and $M \in \text{RMod}_C(\mathcal{C}_{\text{at} \infty}(\mathcal{X}))$, then $c$ exhibits a homotopy equivalence

$$\text{Map}_{\text{RMod}_C(\mathcal{C}_{\text{at} \infty}(\mathcal{X}))}(D \otimes \text{LMod}_A(\mathcal{E}), M) \to \text{Map}_{\mathcal{C}_{\text{at} \infty}(\mathcal{X})}(D, M \otimes_C \text{RMod}_A(\mathcal{E})).$$

This follows from Theorems 4.8.4.1 and 4.8.4.6, which allow us to identify both sides with the the subcategory of $\text{Fun}(D, \text{RMod}_A(M))$ spanned by those functors which preserve $\mathcal{X}$-indexed colimits and equivalences between them.
Remark 4.8.4.9. Let $\mathcal{K}$ be a small collection of simplicial sets which includes $\mathbb{N}(\Delta)^{op}$. Let $\mathcal{C}$ be a monoidal $\infty$-category which admits colimits indexed by simplicial sets belonging to $\mathcal{K}$, and such that the tensor product $\otimes: \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves colimits indexed by simplicial sets belonging to $\mathcal{K}$ separately in each variable. We will identify $\mathcal{C}$ with a algebra object of the symmetric monoidal $\infty$-category $\mathsf{Cat}_{\infty}(\mathcal{K})$ of Corollary 4.8.1.4.

For every algebra object $A \in \mathsf{Alg}(\mathcal{C})$, the $\infty$-category $\mathsf{RMod}_A(\mathcal{C})$ is left-tensored over $\mathcal{C}$, and can therefore be identified with a left $\mathcal{C}$-module object of $\mathsf{Cat}_{\infty}(\mathcal{K})$ (see §4.3.2). We let $\mathsf{Morita}(\mathcal{C})$ denote the full subcategory of $\mathsf{LMod}_C(\mathsf{Cat}_{\infty}(\mathcal{K}))$ spanned by objects of the form $\mathsf{RMod}_A(\mathcal{C})$, where $A \in \mathsf{Alg}(\mathcal{C})$. We will refer to $\mathsf{Morita}(\mathcal{C})$ as the $\mathsf{Morita}$ $\infty$-category of $\mathcal{C}$.

Let $A$ and $B$ be algebra objects of $\mathcal{C}$. Using Theorems 4.8.4.1 and 4.3.2.7, we obtain an equivalence of $\infty$-categories

$$\mathsf{LinFun}_C(\mathsf{RMod}_A(\mathcal{C}), \mathsf{RMod}_B(\mathcal{C})) \simeq \mathsf{LMod}_A(\mathsf{RMod}_B(\mathcal{C})) \simeq \mathsf{ABMod}_B(\mathcal{C}).$$

That is, every $\mathcal{C}$-linear functor from $\mathsf{RMod}_A(\mathcal{C})$ to $\mathsf{RMod}_B(\mathcal{C})$ which preserves $\mathcal{K}$-indexed colimits is given by the formula $M \mapsto M \otimes_A K$, for some bimodule object $K \in \mathsf{ABMod}_B(\mathcal{C})$ (it follows from this description that $\mathsf{Morita}(\mathcal{C})$ is independent of the choice of $\mathcal{K}$, so long as $\mathcal{K}$ includes $\mathbb{N}(\Delta)^{op}$).

The $\mathsf{Morita}$ $\infty$-category of $\mathcal{C}$ can be described informally as follows:

- The objects of $\mathsf{Morita}(\mathcal{C})$ are algebra objects $A \in \mathsf{Alg}(\mathcal{C})$.
- Given a pair of objects $A, B \in \mathsf{Alg}(\mathcal{C})$, the mapping space $\mathsf{Map}_{\mathsf{Morita}(\mathcal{C})}(A, B)$ can be identified with the Kan complex $\mathsf{ABMod}_B(\mathcal{C})^\simeq$.
- Given a triple of objects $A, B, C \in \mathsf{Alg}(\mathcal{C})$, the composition law

$$\mathsf{ABMod}_B(\mathcal{C})^\simeq \times \mathsf{BMod}_C(\mathcal{C})^\simeq \simeq \mathsf{Map}_{\mathsf{Morita}(\mathcal{C})}(A, B) \times \mathsf{Map}_{\mathsf{Morita}(\mathcal{C})}(B, C)$$

$$\rightarrow \mathsf{Map}_{\mathsf{Morita}(\mathcal{C})}(A, C)$$

$$\simeq \mathsf{ABMod}_B(\mathcal{C})^\simeq$$

is given by $(M, N) \mapsto M \otimes_B N$.

The proofs of Theorem 4.8.4.6 and 4.8.4.1 are very similar, and rest on an analysis of the forgetful functor $\mathsf{RMod}_A(\mathcal{C}) \to \mathcal{C}$. We observe that this functor is $\mathcal{C}$-linear. More precisely, evaluation at the object $m \in \mathbb{R}M$ induces a $\mathcal{C}$-linear functor $\mathsf{RMod}_A(\mathcal{C}) \to \mathcal{C}$. We have the following fundamental observation:

Lemma 4.8.4.10. Let $\mathcal{C}^\otimes$ be a monoidal $\infty$-category containing an algebra object $A$, and let $\mathcal{N} = \mathcal{C}$, regarded as an $\infty$-category left-tensored over $\mathcal{C}$. Consider the commutative diagram

$$\begin{array}{ccc}
\mathcal{N}^\otimes & \xrightarrow{G^\otimes} & \Delta \mathsf{RMod}_A(\mathcal{C})^\otimes \\
\downarrow q & & \downarrow \rho' \\
\mathcal{C}^\otimes & & \end{array}$$

where $G$ is determined by the $\mathcal{C}$-linear forgetful functor $\mathsf{RMod}_A(\mathcal{C}) \to \mathcal{C}$. Then there exists a functor $F : \mathcal{N}^\otimes \to \mathsf{RMod}_A(\mathcal{C})^\otimes$ and a natural transformation $\theta : \mathsf{id}_{\mathcal{N}^\otimes} \to G \circ F$ which exhibits $F$ as a left adjoint to $G$ relative to $\mathcal{C}^\otimes$ (see Definition 7.3.2.2 and Remark 7.3.2.3). Moreover, $F$ determines a $\mathcal{C}$-linear functor from $\mathcal{C}$ to $\mathsf{RMod}_A(\mathcal{C})$.

Remark 4.8.4.11. More informally, Lemma 4.8.4.10 asserts that the forgetful functor $\mathsf{RMod}_A(\mathcal{C}) \to \mathcal{C}$ and its left adjoint $C \mapsto C \otimes A$ commute with the action of $\mathcal{C}$ by left multiplication.

Proof. We observe that $p$ and $p'$ are locally coCartesian fibrations (Lemma 4.2.2.19). Moreover, for each object $C \in \mathcal{C}^\otimes$, the induced map on fibers $\mathsf{RMod}_A(\mathcal{C})^\otimes \to \mathcal{N}^\otimes$ is equivalent to the forgetful functor $\theta : \mathsf{RMod}_A(\mathcal{C}) \to \mathcal{C}$, and therefore admits a left adjoint (Corollary 4.2.4.8). We complete the proof by observing that the functor $G$ satisfies hypothesis (2) of Proposition 7.3.2.11. Unwinding the definitions, this results from the observation that the canonical maps $(C \otimes D) \otimes A \to C \otimes (D \otimes A)$ expressing the coherent associativity of the tensor product on $\mathcal{C}$ are equivalences in $\mathcal{C}$. □
The following result provides a reformulation of Definition 4.6.2.7:

**Lemma 4.8.4.12.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category, let \( \mathcal{M} \) and \( \mathcal{N} \) be \( \infty \)-categories left-tensored over \( \mathcal{C} \), and let \( q : \mathcal{M}^\otimes \to \mathcal{C}^\otimes \) and \( q' : \mathcal{N}^\otimes \to \mathcal{C}^\otimes \) be as in Notation 4.2.2.16. Then the evident functor \( \theta : \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N}) \to \text{Fun}_\mathcal{C}(\mathcal{M}^\otimes, \mathcal{N}^\otimes) \) is fully faithful, and its essential image consists of those functors \( \mathcal{M}^\otimes \to \mathcal{N}^\otimes \) which carry locally \( q \)-coCartesian morphisms to locally \( q' \)-coCartesian morphisms.

**Proof.** Let \( \mathcal{X} \) be the full subcategory of \( \text{Fun}_\mathcal{C}(\mathcal{M}^\otimes, \mathcal{N}^\otimes) \) spanned by those functors which carry locally \( q \)-coCartesian morphisms to locally \( q' \)-coCartesian morphisms. We wish to show that \( \theta \) induces an equivalence \( \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N}) \to \mathcal{X} \). Equivalently, we wish to show that for every simplicial set \( K \), the induced map \( \text{Fun}(K, \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N})) \to \text{Fun}(K, \mathcal{X}) \) induces a bijection between equivalence classes of objects. Replacing \( \mathcal{N} \) by \( \text{Fun}(K, \mathcal{N}) \), we can reduce to the case \( K = \Delta^0 \). We will show that \( \theta \) induces a homotopy equivalence between the Kan complexes \( \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N})^\simeq \) and \( \mathcal{X}^\simeq \).

Let \( C : \mathcal{N}(\Delta)^{\text{op}} \to \text{Cat}_\infty \) classify the coCartesian fibration \( \mathcal{C}^\otimes \to \mathcal{N}(\Delta)^{\text{op}} \). The coCartesian fibration \( \mathcal{M}^\otimes \times_{\mathcal{L}_\mathcal{M}} (\Delta^1 \times (\mathcal{N}(\Delta)^{\text{op}}) \to \Delta^1 \times \mathcal{N}(\Delta)^{\text{op}} \to \text{Cat}_\infty \), which we can identify with a natural transformation \( \alpha : M \to C \) in \( \text{Fun}(\mathcal{N}(\Delta)^{\text{op}}, \text{Cat}_\infty) \). Similarly, the coCartesian fibration \( \mathcal{N}^\otimes \times_{\mathcal{L}_\mathcal{N}} (\Delta^1 \times (\mathcal{N}(\Delta)^{\text{op}}) \to \Delta^1 \times \mathcal{N}(\Delta)^{\text{op}} \to \text{Cat}_\infty) \). Using Propositions 4.1.2.6 and 4.2.2.9, we conclude that \( \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N})^\simeq \) can be identified with the homotopy fiber of the forgetful functor

\[
\text{Map}_{\text{Fun}(\Delta^1 \times (\mathcal{N}(\Delta)^{\text{op}}, \text{Cat}_\infty))}(\alpha, \beta) \to \text{Map}_{\text{Fun}(\mathcal{N}(\Delta)^{\text{op}}, \text{Cat}_\infty)}(C, C)
\]

over the point corresponding to \( \text{id}_C \). This can in turn be identified with the homotopy fiber product

\[
\text{Map}_{\text{Fun}(\mathcal{N}(\Delta)^{\text{op}}, \text{Cat}_\infty)}(M, N) \times \text{Map}_{\text{Fun}(\mathcal{N}(\Delta)^{\text{op}}, \text{Cat}_\infty)}(M, C) \{ \alpha \}.
\]

This homotopy fiber is given by \( \mathcal{X}^{\simeq} \), where \( \mathcal{X} \subseteq \text{Fun}_\mathcal{C}(\mathcal{M}^\otimes, \mathcal{N}^\otimes) \) is the full subcategory spanned by those functors \( F \) which carry \( (p \circ q) \)-coCartesian morphisms of \( \mathcal{M}^\otimes \) to \( (p \circ q') \)-coCartesian morphisms of \( \mathcal{N}^\otimes \). Using the functor \( \theta \), we see that \( \mathcal{X} \subseteq \mathcal{X}^{\simeq} \); we will complete the proof by showing that \( \mathcal{X} \subseteq \mathcal{X}^{\simeq} \). Note that a morphism \( f \) in \( \mathcal{M}^\otimes \) is \( (p \circ q) \)-coCartesian if and only if \( q(f) \) is \( p \)-coCartesian and \( f \) is locally \( q \)-coCartesian. It follows that if \( F \in \mathcal{X} \), then \( F(f) \) is locally \( q' \)-coCartesian; since \( q'(F(f)) \simeq q(f) \) is \( p \)-coCartesian we conclude that \( F(f) \) is \( (p \circ q) \)-coCartesian. This proves that \( \mathcal{X} \subseteq \mathcal{X}^{\simeq} \) as desired. \( \square \)

**Lemma 4.8.4.13.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category and let \( \mathcal{M} \) and \( \mathcal{N} \) be \( \infty \)-categories left-tensored over \( \mathcal{C} \). Let \( K \) be a simplicial set such that \( \mathcal{N} \) admits \( K \)-indexed colimits, and such that for each \( C \in \mathcal{C} \), the tensor product functor \( \{ C \} \times N \subseteq \mathcal{C} \times \mathcal{N} \to \mathcal{N} \) preserves \( K \)-indexed colimits. Then:

1. The \( \infty \)-category \( \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N}) \) admits \( K \)-indexed colimits.
2. A map \( f : K^\text{op} \to \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N}) \) is a colimit diagram if and only if, for each \( M \in \mathcal{M} \), the induced map \( K^\text{op} \to \mathcal{N} \) is a colimit diagram.

**Remark 4.8.4.14.** In the situation of Lemma 4.8.4.13, suppose that \( \mathcal{K} \) is a class of simplicial sets such that \( \mathcal{C}, \mathcal{M}, \) and \( \mathcal{N} \) admit \( \mathcal{K} \)-indexed colimits, and the tensor product functors

\[
\mathcal{C} \times \mathcal{C} \to \mathcal{C} \quad \mathcal{C} \times \mathcal{M} \to \mathcal{M} \quad \mathcal{C} \times \mathcal{N} \to \mathcal{N}
\]

preserve \( \mathcal{K} \)-indexed colimits separately in each variable. Then the full subcategory \( \text{LinFun}_\mathcal{C}^\mathcal{K}(\mathcal{M}, \mathcal{N}) \subseteq \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N}) \) is stable under \( K \)-indexed colimits: this follows from the characterization of \( K \)-indexed colimits supplied by Lemma 4.8.4.13 together with Lemma T.5.5.2.3.

**Proof.** Assertion (1) follows from Lemma 4.8.4.12 and Proposition T.5.4.7.11. Proposition T.5.4.7.11 also implies that a diagram \( f : K^\text{op} \to \text{LinFun}_\mathcal{C}(\mathcal{M}, \mathcal{N}) \) is a colimit if and only if, for every object \( M \in \mathcal{M}^\otimes \) having image \( C \in \mathcal{C}^\otimes \) and \( \{ n \} \subseteq \mathcal{N}(\Delta)^{\text{op}} \), the induced map \( f_M : K^\text{op} \to \mathcal{N}^\otimes \) is a colimit diagram. The necessity of condition (2) is now obvious. For the sufficiency, let \( p : \mathcal{C}^\otimes \to \mathcal{N}(\Delta)^{\text{op}}, q : \mathcal{M}^\otimes \to \mathcal{C}^\otimes, \) and \( q' : \mathcal{N}^\otimes \to \mathcal{C}^\otimes \).
be as in Notation 4.2.2.16. Choose a $p$-coCartesian morphism $\alpha : C \to C_0$ in $\mathcal{C}^\otimes$ covering the inclusion $[0] \simeq \{n\} \subseteq [n]$ in $\Delta$ and a locally $q$-coCartesian morphism $\overline{\alpha} : M \to M_0$ lifting $\alpha$, then we have a homotopy commutative diagram

$$
\begin{array}{ccc}
K^\otimes & \xrightarrow{\phi} & \mathcal{C}^\otimes \\
p_M & & \downarrow \phi \\
\mathcal{C}^\otimes & \xrightarrow{\alpha} & \mathcal{C}^\otimes \\
p_M & & \downarrow \alpha \\
N^\otimes_C & \xrightarrow{\overline{\alpha}} & N^\otimes_{C_0}
\end{array}
$$

where $\alpha$ is an equivalence of $\infty$-categories, so that $f_M$ is a colimit if and only if $f_{M_0}$ is a colimit diagram. \qed

We now turn to the proofs of Theorems 4.8.4.1 and 4.8.4.6.

**Proof of Theorem 4.8.4.1.** Let $\mathcal{N} = \mathcal{C}$, and regard $\mathcal{N}$ as an $\infty$-category left-tensored over $\mathcal{C}$. Let $G : \text{RMod}_A(\mathcal{C})^\otimes \to \mathcal{N}^\otimes$ and $F : \mathcal{N}^\otimes \to \text{RMod}(\mathcal{C})^\otimes$ be as in Lemma 4.8.4.10. Then $F$ and $G$ induce adjoint functors

$$
\begin{array}{c}
\text{LinFun}_C^X(\mathcal{N}, \mathcal{M}) \xrightarrow{f} \text{LinFun}_C^X(\text{RMod}_A(\mathcal{C}), \mathcal{M})
\end{array}
$$

We first claim that evaluation at the unit object $\mathbf{1} \in \mathcal{N} \simeq \mathcal{C}$ induces an equivalence of $\infty$-categories $\phi : \text{LinFun}_C^X(\mathcal{N}, \mathcal{M}) \to \mathcal{M}$. It will suffice to show that for every simplicial set $K$, the induced map $\text{Fun}(K, \text{LinFun}_C^X(\mathcal{N}, \mathcal{M})) \to \text{Fun}(K, \mathcal{M})$ induces a bijection on equivalence classes of objects. Replacing $\mathcal{M}$ by $\text{Fun}(K, \mathcal{M})$, we are reduced to proving that $\phi$ induces a bijection on equivalence classes of objects. On the left hand side, the set of equivalence classes can be identified with $\pi_0 \text{Map}_{\text{LMod}^X(\text{Cat}_\infty(\mathcal{X}))}(\mathcal{C}, \mathcal{M})$. Using Corollary 4.2.4.8, we can identify this with the set $\pi_0 \text{Map}_{\text{Cat}_\infty(\mathcal{X})}(\mathcal{C}, \mathcal{M}) \simeq \pi_0 \text{Map}_{\text{Cat}_\infty}(\Delta^0, \mathcal{M})$, which is the set of equivalence classes of objects of $\mathcal{M}$ as required.

Let $T : \text{LinFun}_C^X(\text{RMod}_A(\mathcal{C}), \mathcal{M}) \to \mathcal{M}$ denote the composition of the functor $g$ with the equivalence $\phi$. We have a homotopy commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\text{LinFun}_C^X(\text{RMod}_A(\mathcal{C}), \mathcal{M}) & \xrightarrow{\theta} & \text{LMod}_A(\mathcal{M}) \\
\downarrow T & & \downarrow T' \\
\mathcal{M} & \xrightarrow{\overline{T}} & \mathcal{M}^\prime
\end{array}
$$

where $T$ is the evident forgetful functor. We will prove that $\theta$ is an equivalence showing that this diagram satisfies the hypotheses of Corollary 4.7.4.16:

(a) The $\infty$-categories $\text{LinFun}_C^X(\text{RMod}_A(\mathcal{C}), \mathcal{M})$ and $\text{LMod}_A(\mathcal{M})$ admit geometric realizations of simplicial objects. In the first case, this follows from Lemma 4.8.4.13 and Remark 4.8.4.14. In the second, it follows from Corollary 4.2.3.5.

(b) The functors $T$ and $T'$ admit left adjoints, which we will denote by $U$ and $U'$. The left adjoint $U$ is given by composing $f$ with a homotopy inverse to the equivalence $\phi$, and the left adjoint $U'$ is supplied by Corollary 4.2.4.8.

(c) The functor $T'$ is conservative and preserves geometric realizations of simplicial objects. The first assertion follows from Corollary 4.2.3.2 and the second from Corollary 4.2.3.5.

(d) The functor $T$ is conservative and preserves geometric realizations of simplicial objects. The second assertion follows from Lemma 4.8.4.13. To prove the first, suppose that $\alpha : S \to S'$ is a natural transformation of $\mathcal{C}$-linear functors from $\text{RMod}_A(\mathcal{C})$ to $\mathcal{M}$, each of which preserves $X$-indexed colimits, and that $T(\alpha)$ is an equivalence. We wish to show that $\alpha$ is an equivalence. Let us abuse notation by identifying $S$ and $S'$ with the underlying maps $\text{RMod}_A(\mathcal{C}) \to \mathcal{M}$, and let $X$ be the full subcategory of
Theorem 4.8.4.6. The forgetful functor $\text{RMod}_A(\mathcal{C}) \to \mathcal{C}$ can be viewed as a map between left $\mathcal{C}$-module objects in $\text{Cat}_\infty(\mathcal{X})$, and therefore induces a functor $G : M \otimes_e \text{RMod}_A(\mathcal{C}) \to M \otimes_e \mathcal{C} \simeq M$. Let $G' : \text{RMod}_A(M) \to M$ be the evident forgetful functor. We have a diagram

$$
\begin{array}{ccc}
M \otimes_e \text{RMod}_A(\mathcal{C}) & \xrightarrow{\Phi} & \text{RMod}_A(M) \\
\downarrow G & & \downarrow G' \\
M, & \xrightarrow{\phi} & G' \\
\end{array}
$$

which commutes up to canonical homotopy, where $\Phi$ is the functor defined in Remark 4.8.4.5. To prove that $\Phi$ is an equivalence of $\infty$-categories, it will suffice to show that this diagram satisfies the hypotheses of Corollary 4.7.4.16:

(a) The $\infty$-categories $M \otimes_e \text{RMod}_A(\mathcal{C})$ and $\text{RMod}_A(M)$ admit geometric realizations of simplicial objects. In the first case, this follows from our assumption that $N(\Delta)^{op} \in \mathcal{X}$; in the second case, it follows from Corollary 4.2.3.5 (since $\mathcal{C}$ admits geometric realizations and tensor product with $A$ preserves geometric realizations).

(b) The functors $G$ and $G'$ admit left adjoints, which we will denote by $F$ and $F'$. The existence of $F'$ follows from Corollary 4.2.4.8 (which also shows that $F'$ is given informally by the formula $M \mapsto M \otimes A$). Similar reasoning shows that the forgetful functor $\text{RMod}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint $F_0$. This left adjoint can be promoted to a map of $\infty$-categories left-tensored over $\mathcal{C}$, so that it induces a functor $\text{id} \otimes F_0 : M \otimes_e \mathcal{C} \to M \otimes_e \text{RMod}(\mathcal{C})$ which is left adjoint to $G$.

(c) The functor $G'$ is conservative and preserves geometric realizations of simplicial objects. The first assertion follows from Corollary 4.2.3.2 and the second from Corollary 4.2.3.5 (since $N(\Delta)^{op} \in \mathcal{X}$).

(d) The functor $G$ is conservative and preserves geometric realizations of simplicial objects. The second assertion is obvious (since $G$ is a morphism in $\text{Cat}_\infty(\mathcal{X})$ by construction). The proof that $G$ is conservative is a bit more involved. Let $c : N(\Delta)^{op} \times N(\Delta^+)^{op} \times N(\Delta)^{op} \to N(\Delta)^{op}$ be the concatenation functor, given by the formula $([l],[m],[n]) \mapsto [l] \ast [m] \ast [n] \simeq [l+m+n+2]$, and let $c_0 : N(\Delta)^{op} \times N(\Delta^+)^{op} \times N(\Delta)^{op} \to N(\Delta)^{op}$ be given by $([l],[m],[n]) \mapsto [l] \ast [n]$. The canonical inclusions $[l] \ast [n] \to [l] \ast [m] \ast [n]$ induce a natural transformation of functors $\alpha : c \to c_0$. Let $p : \mathcal{C}^\oplus \to N(\Delta)^{op}$ be the canonical map, let $\pi : \mathcal{C}^\oplus \times_{N(\Delta)^{op}} (N(\Delta)^{op} \times N(\Delta^+)^{op} \times N(\Delta)^{op}) \to \mathcal{C}^\oplus$ denote the projection, and choose a $p$-coCartesian natural transformation $\sigma : \pi \Rightarrow \pi'$ covering $\alpha$. Adjusting $\pi'$ by a homotopy if necessary, we can assume that $\pi'$ induces a functor $T_\bullet : N(\Delta^+)^{op} \times \text{RMod}_A(\mathcal{C})^\oplus \to \text{RMod}_A(\mathcal{C})^\oplus$. We will view the functor $T_\bullet$ as an augmented simplicial object in the category of left $\mathcal{C}$-module functors from $\text{RMod}_A(\mathcal{C})$ to itself, given informally by the formula $T_n(N) = N \otimes A^{\otimes (n+1)}$; in particular, the functor $T_{-1}$ is equivalent to the identity functor. For each object $N \in \text{RMod}_A(\mathcal{C})$, the canonical map $\epsilon : |T_\bullet N| \to T_{-1}N \simeq N$ is an equivalence: to prove this, it suffices to show that the image of $\epsilon$ under the forgetful functor $\theta : \text{RMod}_A(\mathcal{C}) \to \mathcal{C}$ is an equivalence (Corollary 4.2.3.2): we note that $\theta|T_\bullet N$
can be identified with the relative tensor product \( N \otimes_A A \) and that \( \theta(e) \) is the canonical equivalence \( N \otimes_A A \cong N \).

Using Lemma 4.8.4.3, we see that \( T_* \) determines an augmented simplicial object \( U_* : N(\Delta^n)^{op} \to \text{Fun}(\mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E}), \mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E})) \). Note that each \( U_n \) preserves \( \mathcal{K} \)-indexed colimits. Let \( \mathcal{X} \) be the full subcategory of \( \mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E}) \) spanned by those objects for which the canonical map \( [\mathcal{U}_* \mathcal{X}] \to U_n \mathcal{X} \cong \mathcal{X} \) is an equivalence. Since each \( U_n \) preserves \( \mathcal{K} \)-indexed colimits, the full subcategory \( \mathcal{X} \) is stable under \( \mathcal{K} \)-indexed colimits in \( \mathcal{M} \otimes \mathcal{E} \text{Mod}(\mathcal{E}) \). Because \( \mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E}) \) is generated under \( \mathcal{K} \)-indexed colimits by the essential image of the tensor product functor \( \otimes : \mathcal{M} \times \text{Mod}_A(\mathcal{E}) \to \mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E}) \) (which obviously belongs to \( \mathcal{X} \)), we conclude that \( \mathcal{X} = \mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E}) \).

Now suppose that \( f : X \to Y \) is a morphism in \( \mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E}) \) such that \( G(f) \) is an equivalence. We wish to prove that \( f \) is an equivalence. Note that \( f \) is equivalent to the geometric realization \( [\mathcal{U}_* f] \) (in the \( \infty \)-category \( \text{Fun}(\Delta^1, \mathcal{M} \otimes \mathcal{E} \text{Mod}_A(\mathcal{E})) \)); it therefore suffices to show that \( U_n(f) \) is an equivalence for \( n \geq 0 \). We complete the argument by observing that \( U_n \) factors through \( G \) (since \( T_n \) factors through the forgetful functor \( \text{Mod}_A(\mathcal{E}) \to \mathcal{E} \)).

(e) The canonical natural transformation \( G' \circ F' \to G \circ F \) is an equivalence of functors from \( \mathcal{M} \) to itself. This follows easily from the descriptions of \( F \) and \( F' \) given above: both functors are given by tensor product with \( A \).

\[ \square \]

### 4.8.5 Behavior of the Functor \( \Theta \)

In §4.3.2, we saw that if \( \mathcal{E}^{\otimes} \to \mathcal{Ass}^{\otimes} \) is a monoidal \( \infty \)-category and \( A \) is an algebra object of \( \mathcal{E} \), then the \( \infty \)-category \( \mathcal{M} \text{Mod}_A(\mathcal{E}) \) of right \( A \)-module objects of \( \mathcal{E} \) is left-tensored over \( \mathcal{E} \). Moreover, in §4.8.3 we showed that the construction \( (\mathcal{E}^{\otimes}, A) \to (\mathcal{E}^{\otimes}, \mathcal{M} \text{Mod}_A(\mathcal{E})) \) determines a functor

\[ \Theta : \mathcal{Cat}^{\text{Alg}}(\mathcal{K}) \to \mathcal{Cat}^{\text{Mod}}(\mathcal{K}) \]

for any collection of simplicial sets \( \mathcal{K} \) which contains \( N(\Delta)^{op} \) (see Construction 4.8.3.24). In this section, we will apply the main results of §4.8.4 (Theorems 4.8.4.6 and 4.8.4.1) to establish some basic formal properties of \( \Theta \). We can describe our goals more specifically as follows:

1. If \( A \) is an associative ring, we can almost recover \( A \) from the category \( \mathcal{M} \text{Mod}_A(\mathcal{E}) \) of right \( A \)-modules. More precisely, if we let \( M \) denote the ring \( A \) itself, regarded as a right \( A \)-module, then left multiplication by elements of \( A \) determines a canonical isomorphism \( A \to \text{Hom}_\mathcal{M}(M, M) \). In other words, the data of the associative ring \( A \) is equivalent to the data of the category \( \mathcal{M} \text{Mod}_A(\mathcal{E}) \) together with its distinguished object \( M \). An analogous result holds if we replace the category of abelian groups by a more general monoidal \( \infty \)-category \( \mathcal{E} \): the functor \( \Theta \) induces a fully faithful embedding \( \Theta_* \) from the \( \infty \)-category \( \mathcal{Cat}^{\text{Alg}}(\mathcal{K}) \) to the \( \infty \)-category of triples \( (\mathcal{E}^{\otimes}, \mathcal{M}, M) \), where \( \mathcal{E}^{\otimes} \) is a monoidal \( \infty \)-category, \( \mathcal{M} \) is an \( \infty \)-category left-tensored over \( \mathcal{E} \), and \( M \in \mathcal{M} \) is a distinguished object. We refer the reader to Theorem 4.8.5.5 for a precise statement.

2. If we work in the setting of presentable \( \infty \)-categories, then the functor \( \Theta_* \) admits a right adjoint, which carries a triple \( (\mathcal{E}^{\otimes}, \mathcal{M}, M) \) to the pair \( (\mathcal{E}^{\otimes}, A) \), where \( A \in \mathcal{Alg}(\mathcal{E}) \) is the algebra of endomorphisms of \( M \) (Theorem 4.8.5.11).

3. The \( \infty \)-categories \( \mathcal{Cat}^{\text{Alg}}(\mathcal{K}) \) and \( \mathcal{Cat}^{\text{Mod}}(\mathcal{K}) \) admit symmetric monoidal structures, and \( \Theta \) can be promoted to a symmetric monoidal functor (Theorem 4.8.5.16).

We begin by addressing a small technical point regarding the behavior of the functor \( \Theta \) with respect to base change:
Proposition 4.8.5.1. Let $\mathcal{K}$ be a small collection of simplicial sets which includes $N(\Delta)^{op}$, and consider the commutative diagram

$$
\begin{array}{ccc}
\mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K}) & \xrightarrow{\phi} & \mathbf{Cat}^{\text{Mod}}_{\infty}(\mathcal{K}) \\
\mathbf{Mon}^X_{\text{Ass}}(\mathbf{Cat}_{\infty}) & \xrightarrow{\psi} & \\
\end{array}
$$

The functors $\phi$ and $\psi$ are coCartesian fibrations, and the functor $\Theta$ carries $\phi$-coCartesian morphisms to $\psi$-coCartesian morphisms.

Proof. We first show that $\phi$ is a coCartesian fibration. Let $\mathbf{Mon}_{\text{Ass}}^{\mathcal{K}}(\mathbf{Cat}_{\infty})$ be as defined in Notation 4.8.3.5, and set

$$
\mathcal{X} = \mathbf{Fun}(\mathbf{Ass}^{\circ}, \mathbf{Mon}_{\text{Ass}}^{\mathcal{K}}(\mathbf{Cat}_{\infty})) \times \mathbf{Fun}(\mathbf{Ass}^{\circ}, \mathbf{Ass}^{\circ} \times \mathbf{Mon}^X_{\text{Ass}}(\mathbf{Cat}_{\infty})) \mathbf{Mon}^X_{\text{Ass}}(\mathbf{Cat}_{\infty})
$$

Let us denote an object of $\mathcal{X}$ by a pair $(\mathbb{C}^{\circ}, A)$, where $\mathbb{C}^{\circ}$ is a monoidal $\infty$-category (compatible with $\mathcal{K}$-indexed colimits) and $A \in \mathbf{Fun}_{\mathbf{Ass}^{\circ}}(\mathbf{Ass}^{\circ}, \mathbb{C}^{\circ})$. It follows from Proposition T.3.1.2.1 that the projection map $\phi' : \mathcal{X} \rightarrow \mathbf{Mon}^X_{\text{Ass}}(\mathbf{Cat}_{\infty})$ is a coCartesian fibration; moreover, a morphism $(\mathbb{C}^{\circ}, A) \rightarrow (\mathbb{D}^{\circ}, B)$ in $\mathcal{X}$ is $\phi'$-coCartesian if and only if the underlying map $F(A) \rightarrow B$ is an equivalence, where $F : \mathbb{C}^{\circ} \rightarrow \mathbb{D}^{\circ}$ denotes the underlying monoidal functor. In this case, if $A$ is an algebra object of $\mathbb{C}^{\circ}$, then $B \simeq F(A)$ is an algebra object of $\mathbb{D}^{\circ}$. Note that $\mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})$ can be identified with the full subcategory of $\mathcal{X}$ spanned by those pairs $(\mathbb{C}^{\circ}, A)$ where $A$ is an algebra object of $\mathbb{C}^{\circ}$. It follows that if $f : X \rightarrow Y$ is a $\phi'$-coCartesian morphism of $\mathcal{X}$ such that $X \in \mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})$, then $Y \in \mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})$. We conclude that $\phi = \phi' | \mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})$ is again a coCartesian fibration, and that a morphism in $\mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})$ is $\phi$-coCartesian if and only if it is $\phi'$-coCartesian.

We next prove that $\psi$ is a coCartesian fibration. Note that $\mathbf{Cat}^{\text{Mod}}_{\infty}(\mathcal{K}) \simeq \mathbf{LMod}(\mathbf{Cat}_{\infty}(\mathcal{K}))$ and the functor $\psi$ can be identified with the forgetful functor $\mathbf{LMod}(\mathbf{Cat}_{\infty}(\mathcal{K})) \rightarrow \mathbf{Alg}(\mathbf{Cat}_{\infty}(\mathcal{K}))$, and is therefore a Cartesian fibration (Corollary 4.2.3.2). Consequently, to prove that $\psi$ is a coCartesian fibration, it will suffice to show that for every morphism $F : \mathbb{C}^{\circ} \rightarrow \mathbb{D}^{\circ}$ in the $\infty$-category $\mathbf{Alg}(\mathbf{Cat}_{\infty}(\mathcal{K})) \simeq \mathbf{Mon}^X_{\text{Ass}}(\mathbf{Cat}_{\infty})$, the forgetful functor $\mathbf{LMod}_{\mathbb{C}^{\circ}}(\mathbf{Cat}_{\infty}(\mathcal{K})) \rightarrow \mathbf{LMod}_{\mathbb{D}^{\circ}}(\mathbf{Cat}_{\infty}(\mathcal{K}))$ admits a left adjoint. This follows immediately from Lemma 4.8.4.2 and Proposition 4.6.2.17.

It remains only to prove that $\Theta$ carries $\phi$-coCartesian morphisms to $\psi$-coCartesian morphisms. Unwinding the definitions, we must show that if $F : \mathbb{C}^{\circ} \rightarrow \mathbb{D}^{\circ}$ is a morphism in $\mathbf{Alg}(\mathbf{Cat}_{\infty}(\mathcal{K}))$ and $A$ is an algebra object of $\mathbb{C}^{\circ}$, then the canonical map $\rho : \mathbf{RMod}_{\mathbb{D}^{\circ}}(\mathbf{Cat}_{\infty}(\mathcal{K})) \rightarrow \mathbf{RMod}_{\mathbb{C}^{\circ}}(\mathbf{Cat}_{\infty}(\mathcal{K}))$ is an equivalence of $\infty$-categories (each of which is left-tensored over $\mathbb{D}$). Note that $\mathbf{RMod}_{\mathbb{D}}(\mathbb{D})$ can be identified with the $\infty$-category $\mathbf{RMod}_{\mathbb{D}}(\mathbb{D})$, where we regard $\mathbb{D}$ as right-tensored over the $\infty$-category $\mathbb{C}$ via the monoidal functor $F$. Under this identification, the functor $\rho$ is given by the equivalence of Theorem 4.8.4.6.

Let us now study the image of the initial object of $\mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})$ under the functor $\Theta$.

Notation 4.8.5.2. Fix a small collection of simplicial sets $\mathcal{K}$. We let $S(\mathcal{K})$ denote the unit object of the monoidal $\infty$-category $\mathbf{Cat}_{\infty}(\mathcal{K})$: it can be described concretely as the smallest full subcategory of $S$ which contains the final object $\Delta^0$ and is closed under $\mathcal{K}$-filtered colimits (Remark T.5.3.5.9). Since the formation of Cartesian products in $S$ preserves small colimits in each variable, the full subcategory $S(\mathcal{K}) \subseteq S$ is stable under finite products. We may therefore regard $S(\mathcal{K})$ as equipped with the Cartesian monoidal structure, which endows it with the structure of an algebra object of $\mathbf{Cat}_{\infty}(\mathcal{K})$. We let $\mathfrak{R}$ denote the object of $\mathbf{Cat}_{\infty}(\mathcal{K})$ given by the left action of $S(\mathcal{K})$ on itself.

Using Proposition 4.2.4.9, we can identify $\mathfrak{R}$ with $\Theta(S(\mathcal{K})^{\times}, 1)$, where $1$ denotes the unit object $\Delta^0 \in S(\mathcal{K})$, regarded as an algebra object of $S(\mathcal{K})$.

Lemma 4.8.5.3. Let $\mathcal{K}$ be a small collection of simplicial sets. Then the pair $(S(\mathcal{K})^{\times}, 1)$ is an initial object of $\mathbf{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})$. 

\[\square\]
Proof. Let \( \phi : \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K}) \to \text{Mon}_{\mathcal{K}}^{\mathcal{X}}(\mathsf{Cat}_{\infty}) \) denote the forgetful functor. Then \( \phi(S(\mathcal{X})^\times, 1) \) is an initial object of \( \text{Mon}_{\mathcal{K}}^{\mathcal{X}}(\mathsf{Cat}_{\infty}) \cong \mathsf{Alg}(\mathsf{Cat}_{\infty}(\mathcal{K})) \) (Proposition 3.2.1.8). It will therefore suffice to show that \( (S(\mathcal{X})^\times, 1) \) is a \( \phi \)-initial object of \( \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K}) \) (Proposition T.4.3.1.5). Since \( \phi \) is a coCartesian fibration (Proposition 4.8.5.1), this is equivalent to the requirement that for every \( \phi \)-coCartesian morphism \( \alpha : (S(\mathcal{X})^\times, 1) \to (\mathcal{E}^\circ, A) \), the object \( A \) is initial in the fiber \( \phi^{-1}(\mathcal{E}^\circ) \cong \mathsf{Alg}(\mathcal{E}) \) (Proposition T.4.3.1.10). This follows immediately from Proposition 3.2.1.8.

It follows from Lemma 4.8.5.3 that the forgetful functor \( \theta : \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K})(S(\mathcal{X})^\times, 1)/ \to \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K}) \) is a trivial Kan fibration. We let \( \Theta_* \) denote the composition

\[
\mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K}) \cong \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K})(S(\mathcal{X})^\times, 1)/ \to \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K})_{\text{gr}}/,
\]

where the first map is given by a section of \( \theta \).

**Remark 4.8.5.4.** An object of the \( \infty \)-category \( \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K})_{\text{gr}}/ \) is given by a morphism \( (S(\mathcal{X})^\times, S(\mathcal{X})) \to (\mathcal{E}^\circ, M) \) in \( \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K}) \), given by a monoidal functor \( S(\mathcal{X})^\times \to \mathcal{E}^\circ \) which preserves \( \mathcal{K} \)-indexed colimits (which is unique up to a contractible space of choices by Proposition 3.2.1.8) together with a functor \( f : S(\mathcal{X}) \to M \) which preserves \( \mathcal{K} \)-indexed colimits. In view of Remark 7.3.5.9, such a functor is determined uniquely up to equivalence by the object \( f(\Delta^0) \in M \). Consequently, we can informally regard \( \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K})_{\text{gr}}/ \) as an \( \infty \)-category whose objects are triples \( (\mathcal{E}^\circ, M, M) \), where \( (\mathcal{E}^\circ, M) \in \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K}) \) and \( M \in M \) is an object.

**Theorem 4.8.5.5.** Let \( \mathcal{K} \) be a small collection of simplicial sets which contains \( N(\Delta)^{\text{op}} \). Then the functor \( \Theta_* : \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K}) \to \mathsf{Cat}_{\infty}^{\mathcal{K}}(\mathcal{K})_{\text{gr}}/ \) is fully faithful.

**Corollary 4.8.5.6.** For every pair of algebra objects \( A, B \in \mathfrak{C} \), let \( \theta : \text{Map}_{\mathcal{C}}(A, B) \to \mathcal{A} \mathfrak{B} \text{Mod}_{\mathcal{B}}(\mathcal{E}) \) carry a map \( \phi : A \to B \) to the image of \( B \) under the forgetful functor \( \mathcal{A} \mathfrak{B} \text{Mod}_{\mathcal{B}}(\mathcal{E}) \to \mathcal{A} \mathfrak{B} \text{Mod}_{\mathcal{B}}(\mathcal{E}) \) determined by \( \phi \). Then \( \theta \) induces a homotopy equivalence

\[
\text{Map}_{\mathcal{C}}(A, B) \to \mathcal{A} \mathfrak{B} \text{Mod}_{\mathcal{B}}(\mathcal{E}) \times \mathfrak{R} \text{Mod}_{\mathcal{B}}(\mathcal{E}) \{B\}.
\]

**Proof.** Enlarging \( \mathcal{C} \) if necessary, we may suppose that \( \mathcal{C} \) admits geometric realizations of simplicial objects and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects. Set \( \mathcal{K} = \{N(\Delta)^{\text{op}}\} \), and regard \( \mathcal{C} \) as an algebra object of the \( \infty \)-category \( \mathcal{X} = \mathsf{Cat}_{\infty}(\mathcal{C}) \). According to Theorem 4.8.5.5, the construction \( R \mapsto \text{LMod}_{R}(\mathcal{C}) \) determines a full faithful embedding \( \mathsf{Alg}(\mathcal{C}) \to (\text{LMod}_{\mathcal{C}}(\mathcal{X}))_{\mathcal{C}/} \), so that the canonical map

\[
\text{Map}_{\mathsf{Alg}(\mathcal{C})}(A, B) \to \text{Map}_{\text{LMod}_{\mathcal{C}}(\mathcal{X})}(\mathfrak{R} \text{Mod}_{\mathcal{C}}(\mathcal{A}), \mathfrak{R} \text{Mod}_{\mathcal{C}}(\mathcal{B})) \times \mathfrak{R} \text{Mod}_{\mathcal{C}}(\mathcal{B}) \{B\}
\]

is a homotopy equivalence. We now invoke Theorems 4.8.4.1 and 4.3.2.7 to identify the underlying Kan complex of \( \mathfrak{A} \mathfrak{B} \text{Mod}_{\mathfrak{B}}(\mathfrak{C}) \) with the mapping space \( \text{Map}_{\text{LMod}_{\mathcal{C}}(\mathcal{X})}(\mathfrak{R} \text{Mod}_{\mathcal{C}}(\mathfrak{A}), \mathfrak{R} \text{Mod}_{\mathcal{C}}(\mathfrak{B})) \).
is a homotopy equivalence. It will suffice to prove the result after passing to the homotopy fiber over a point of $\text{Map}_{\text{Mod}_{\infty}(\mathcal{C})}(\mathcal{D}^\otimes, \mathcal{E}^\otimes)$, corresponding to a monoidal functor $F$. Using Propositions 4.8.5.1 and T.2.4.4.2 and replacing $\mathcal{D}^\otimes$ by $\mathcal{E}^\otimes$ (and $A$ by $FA \in \text{Alg}(\mathcal{E})$), we are reduced to proving that the diagram

$$
\begin{array}{ccc}
\text{Map}_{\text{Alg}(\mathcal{E})}(A, E) & \longrightarrow & \text{Map}_{\text{Mod}_{\infty}(\mathcal{C})}(\text{RMod}_A(\mathcal{E}), M) \\
\downarrow & & \downarrow \\
\{M\} & \longrightarrow & M
\end{array}
$$

is a pullback square. Theorem 4.8.4.1 allows us to identify the upper right corner of this diagram with the $\infty$-category $\text{LMod}_A(M)$, and the desired result follows from Corollary 4.7.2.41. \qed

Proof of Theorem 4.8.5.5. Fix objects $(\mathcal{E}, A), (\mathcal{D}, B) \in \mathcal{C}$. We wish to show that the canonical map $\theta : \text{Map}_{\mathcal{C}}(\mathcal{E}, (\mathcal{D})) \to \text{Map}_{\mathcal{C}}(\text{LMod}_{\infty}(\mathcal{X})/\text{Mon}(\mathcal{X}), (\Theta_*(\mathcal{E}, A), \Theta_*(\mathcal{D}))$ is a homotopy equivalence. Let $M \in \text{RMod}_{\text{B}}(\mathcal{D})$ denote the right $B$-module given by the action of $B$ on itself. In view of Lemma 4.8.5.7, it will suffice to show that the canonical map $m : B \otimes M \to M$ exhibits $B$ as a morphism object $\text{MoRMod}_{\text{B}}(\mathcal{D})(M, M)$. In other words, we must show that for every object $D \in \mathcal{D}$, the multiplication map $m$ induces a homotopy equivalence $\text{Map}_{\mathcal{D}}(D, B) \to \text{Map}_{\text{RMod}_{\text{B}}(\mathcal{D})}(D \otimes M, M)$. This follows from Proposition 4.2.4.2. \qed

It is not difficult to describe the essential image of the fully faithful embedding $\Theta_* : \mathcal{C} \to \mathcal{C}'$ of Theorem 4.8.5.5:

**Proposition 4.8.5.8.** Let $\mathcal{C}$ be a monoidal $\infty$-category. Assume that $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations. Let $\mathcal{M}$ be an $\infty$-category left-tensored over $\mathcal{C}$ and let $M \in \mathcal{M}$ be an object. There exists an algebra object $A \in \text{Alg}(\mathcal{C})$ and an equivalence $\text{RMod}_A(\mathcal{C}) \simeq \mathcal{M}$ of $\infty$-categories left-tensored over $\mathcal{C}$ which carries $A$ to $M$ if and only if the following conditions are satisfied:

1. The $\infty$-category $\mathcal{M}$ admits geometric realizations of simplicial objects.
2. The action map $\mathcal{C} \times \mathcal{M} \to \mathcal{M}$ preserves geometric realizations of simplicial objects.
3. The functor $F : \mathcal{C} \to \mathcal{M}$ given by $F(C) = C \otimes M$ admits a right adjoint $G$.
4. The functor $G$ preserves geometric realizations of simplicial objects.
5. The functor $G$ is conservative.
6. For every object $N \in \mathcal{M}$ and every object $C \in \mathcal{C}$, the evident map $F(C \otimes G(N)) \simeq C \otimes G(N) \otimes M \simeq C \otimes G(N) \to C \otimes N$

is adjoint to an equivalence $C \otimes G(N) \to G(C \otimes N)$.

Proof. We first prove the "only if" direction. Without loss of generality, we may assume that $\mathcal{M} = \text{RMod}_A(\mathcal{C})$ and $M = A$. Assertion (3) is clear: the functor $G$ can be identified with the forgetful functor $\text{RMod}_A(\mathcal{C}) \to \mathcal{C}$ (see Corollary 4.2.4.8). Assertions (1), (2), and (4) follow from Corollary 4.2.3.5, and assertion (5) from Corollary 4.2.3.2. Assertion (6) follows from the observation that the forgetful functor $\text{RMod}_A(\mathcal{C}) \to \mathcal{C}$ is conservative and commutes with the left action of $\mathcal{C}$.

Now suppose that conditions (1) through (6) are satisfied. Fix $A = G(M) \in \mathcal{C}$. We have a counit map $v : A \otimes M \to M$ with the following universal property: for every object $C \in \mathcal{C}$, composition with $v$ induces a homotopy equivalence

$$
\text{Map}_{\mathcal{C}}(C, A) \to \text{Map}_{\mathcal{M}}(C \otimes M, A \otimes M) \to \text{Map}_{\mathcal{M}}(C \otimes M, M).
$$
4.8. TENSOR PRODUCTS OF $\infty$-CATEGORIES

In other words, we can identify $A$ with a morphism object $\text{Mor}_M(M, M)$. It is therefore a final object of the monoidal $\infty$-category $\mathcal{C}^+[M]$; it follows that $A$ can be regarded as an algebra object of $\mathcal{C}$ and that $M$ has the structure of a left module over $A$. Using Theorem 4.8.4.6, we deduce the existence of a $\mathcal{C}$-linear functor $U : \text{RMod}_A(\mathcal{C}) \to M$ carrying $A$ to $M$. To complete the proof, it will suffice to show that $U$ is an equivalence of $\infty$-categories.

Let $G' : \text{RMod}_A(\mathcal{C}) \to \mathcal{C}$ be the forgetful functor and $F'$ a left adjoint to $G'$. Proposition 4.2.4.2 allows us to identify $F'$ with the free module functor $C \mapsto C \otimes A$, so that $F \simeq U \circ F'$. This equivalence is adjoint to a natural transformation $\gamma : G' \to G \circ U$. We claim that $\gamma$ is an equivalence of functors. Using condition (4), we see that $G', G$, and $U$ commute with geometric realizations of simplicial objects. Since every right $A$-module $N$ can be written as a geometric realization of free right $A$-modules (Proposition 4.7.4.14), we see that it suffices to prove that $\gamma$ induces an equivalence

$$C \otimes A \to (G \circ U)(C \otimes A) \simeq G(C \otimes M)$$

for $C \in \mathcal{C}$, which is a special case of (6).

We now deduce that $U$ is an equivalence of $\infty$-categories by applying Corollary 4.7.4.16 to the (homotopy commutative) diagram

$$\begin{array}{ccc}
\text{RMod}_A(\mathcal{C}) & \xrightarrow{U} & M \\
\downarrow G' & & \downarrow G \\
\mathcal{C} & \xrightarrow{G} & \mathcal{C}
\end{array}$$

**Remark 4.8.5.9.** Fix a monoidal $\infty$-category $\mathcal{C}$ which admits geometric realizations of simplicial objects, and assume that the tensor product functor $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects. Theorem 4.8.5.5 implies that $\Theta_*$ determines a fully faithful embedding from $\text{Alg}(\mathcal{C})$ to the $\infty$-category $\text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K}))_{/\mathcal{C}}$ of pointed $\mathcal{C}$-module objects of $\text{Cat}_\infty(\mathcal{K})$, where $\mathcal{K} = \{N(\Delta)^{op}\}$. In fact, something slightly stronger is true: $\text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K}))_{/\mathcal{C}}$ can be identified with the underlying $\infty$-category of an $(\infty, 2)$-category, and $\Theta_*$ is fully faithful at the level of $(\infty, 2)$-categories. More concretely: given algebra objects $A, B \in \text{Alg}(\mathcal{C})$ and $\mathcal{C}$-linear functors $f, g : \text{RMod}_A(\mathcal{C}) \to \text{RMod}_B(\mathcal{C})$ satisfying $f(A) = g(A) = B$, any $\mathcal{C}$-linear natural transformation $\alpha : f \to g$ which induces an equivalence $\alpha_A : B \simeq f(A) \to g(A) \simeq B$ is itself an equivalence. To prove this, let $\mathcal{X} \subseteq \text{RMod}_A(\mathcal{C})$ be the full subcategory spanned by those objects $M$ for which $\alpha_M : f(M) \to g(M)$ is an equivalence. We wish to prove that $\mathcal{X} = \text{RMod}_A(\mathcal{C})$. Since $f$ and $g$ preserve geometric realizations, $\mathcal{X}$ is stable under the formation of geometric realizations. Since every right $A$-module is a geometric realization of free right $A$-modules (Proposition 4.7.4.14), it suffices to show that every free module $C \otimes A \in \text{RMod}_A(\mathcal{C})$ belongs to $\mathcal{X}$. Since $\alpha$ is $\mathcal{C}$-linear, $\mathcal{X}$ is stable under the left action of $\mathcal{C}$; we are therefore reduced to showing that the right module $A$ belongs to $\mathcal{X}$, which is true by assumption.

Lemma 4.8.5.7 can also be used to show that the fully faithful embedding $\Theta_*$ admits a right adjoint, provided that we can guarantee the existence of endomorphism objects $\text{Mor}_M(M, M)$. For this, it is convenient to work in a setting where we require all $\infty$-categories to be presentable. For this, we need to introduce a bit of terminology.

**Notation 4.8.5.10.** Let $\text{Cat}_\infty$ denote the $\infty$-category of (not necessarily small) $\infty$-categories, which contains $\text{Cat}_\infty$ as a full subcategory. Similarly, we define $\infty$-categories $\text{Cat}_\infty^{\text{Alg}} \supset \text{Cat}_\infty^{\text{Alg}}$ and $\text{Cat}_\infty^{\text{Mod}} \supset \text{Cat}_\infty^{\text{Mod}}$ by allowing monoidal $\infty$-categories and left-tensored $\infty$-categories which are not small. Let $\mathcal{K}$ denote the collection of all small simplicial sets, and let $\text{Cat}_\infty^{\text{Alg}}(\mathcal{K})$ and $\text{Cat}_\infty^{\text{Mod}}(\mathcal{K})$ be defined as in §4.8.3. Construction 4.8.3.24 generalizes immediately to give a functor $\tilde{\Theta} : \text{Cat}_\infty(\mathcal{K}) \to \text{Cat}_\infty(\mathcal{K})$. We let $\mathcal{P}_\text{Alg}^{\text{Cat}}$ denote the full subcategory of $\text{Cat}_\infty^{\text{Alg}}(\mathcal{K})$ spanned by those pairs $(\mathcal{E}^{\otimes}, A)$ where the $\infty$-category $\mathcal{C}$ is presentable, and $\mathcal{P}_\text{Mod}^{\text{Cat}}$ the full subcategory of $\text{Cat}_\infty^{\text{Mod}}(\mathcal{K})$ spanned by those pairs $(\mathcal{E}^{\otimes}, M)$ where $\mathcal{C}$ and $M$ are both presentable. It
follows from Corollary 4.2.3.7 that the functor \( \hat{\Theta} : \hat{\mathcal{C}}_{\text{Alg}}(\mathcal{K}) \to \hat{\mathcal{C}}_{\text{Mod}}(\mathcal{K}) \) restricts to a functor \( \hat{\mathcal{P}}_{\text{Alg}} \to \hat{\mathcal{P}}_{\text{Mod}} \), which we will also denote by \( \hat{\Theta} \). Similarly, if we let \( \mathcal{M} \) denote the object \( \Theta(S^\infty, \Delta^0) \simeq (S^\infty, S) \in \hat{\mathcal{P}}_{\text{Mod}} \), then we have a functor \( \hat{\Theta}_* : \hat{\mathcal{P}}_{\text{Alg}} \to \hat{\mathcal{P}}_{\text{Mod}}^\mathcal{M} \).

**Theorem 4.8.5.11.** The functor \( \hat{\Theta}_* : \hat{\mathcal{P}}_{\text{Alg}} \to \hat{\mathcal{P}}_{\text{Mod}}^\mathcal{M} \) is fully faithful and admits a right adjoint.

**Proof.** The first assertion follows by applying Theorem 4.8.5.5 in a larger universe. For the second, it will suffice to show that for every object \( X = (\mathcal{C}^\otimes, \mathcal{M}, M) \in \hat{\mathcal{P}}_{\text{Mod}}^\mathcal{M} \), the right fibration \( \hat{\mathcal{P}}_{\text{Alg}} \times \hat{\mathcal{P}}_{\text{Mod}}^\mathcal{M}(\hat{\mathcal{P}}_{\text{Mod}}^\mathcal{M})/X \) is representable (Proposition T.5.2.4.2). In view of Lemma 4.8.5.3, it will suffice to show that there exists an algebra object \( E \in \text{Alg}(\mathcal{C}) \) such that \( M \) can be promoted to a module \( \hat{\mathcal{M}} \in \text{LMod}_E(\mathcal{C}) \) such that the action \( E \otimes M \to M \) exhibits \( E \) as a morphism object \( \text{Mor}_M(\mathcal{M}, M) \). This is equivalent to requiring the existence of an algebra object \( E \in \Delta \text{Alg}(\mathcal{C}^+[M]) \) such that the underlying object in \( \mathcal{C}^+[M] \) is final. According to Corollary 3.2.2.4, it will suffice to show that \( \mathcal{C}^+[M] \) has a final object (which then admits an essentially unique algebra structure): that is, it will suffice to show that there exists a morphism object \( \text{Mor}_M(\mathcal{M}, M) \).

This follows from Proposition 4.2.1.33. \( \square \)

**Remark 4.8.5.12.** More informally, the right adjoint to \( \hat{\Theta}_* \) carries an object \( (\mathcal{C}^\otimes, \mathcal{M}, M) \in \hat{\mathcal{P}}_{\text{Mod}}^\mathcal{M} \) to the pair \( (\mathcal{C}, E) \in \hat{\mathcal{P}}_{\text{Alg}} \), where \( E \in \text{Alg}(\mathcal{C}) \) is the algebra of endomorphisms of the object \( M \in \mathcal{M} \).

Let \( \mathcal{C}^\otimes \) be a presentable monoidal \( \infty \)-category for which the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves small colimits separately in each variable. Then the functor \( \hat{\Theta}_* \) of Theorem 4.8.5.11 restricts to a map

\[
\text{Alg}(\mathcal{C}) \to \text{LMod}_\mathcal{C}(\hat{\mathcal{P}}_{\text{L}})/\mathcal{C}
\]

\[
A \mapsto \text{RMod}_A(\mathcal{C}).
\]

The proof of Theorem 4.8.5.11 shows that this functor admits a right adjoint. In particular, it preserves small colimits. Combining this observation with Proposition T.4.4.2.9, we obtain the following:

**Corollary 4.8.5.13.** Let \( \mathcal{C}^\otimes \) be a presentable monoidal \( \infty \)-category for which the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves small colimits separately in each variable. Then the functor

\[
\text{Alg}(\mathcal{C}) \to \text{LMod}_\mathcal{C}(\hat{\mathcal{P}}_{\text{L}})
\]

\[
A \mapsto \text{RMod}_A(\mathcal{C})
\]

preserves \( K \)-indexed colimits for every small weakly contractible simplicial set \( K \).

We next investigate the behavior of the functor \( \Theta \) with respect to tensor products of \( \infty \)-categories.

**Notation 4.8.5.14.** The \( \infty \)-category \( \text{Mon}_{\text{Ass}}(\hat{\mathcal{C}}_{\infty}) \) of monoidal \( \infty \)-categories admits finite products, and can therefore be regarded as endowed with Cartesian symmetric monoidal structure. Let \( \mathcal{K} \) be a small collection of simplicial sets. We define a subcategory \( \text{Mon}_{\text{Ass}}^\mathcal{K}(\hat{\mathcal{C}}_{\infty})^\otimes \subseteq \text{Mon}_{\text{Ass}}(\hat{\mathcal{C}}_{\infty})^\otimes \) as follows:

1. Let \( C \) be an object of \( \text{Mon}_{\text{Ass}}(\hat{\mathcal{C}}_{\infty})^\otimes \), given by a sequence of monoidal \( \infty \)-categories \( (\mathcal{C}^\otimes_1, \ldots, \mathcal{C}^\otimes_n) \).
   Then \( C \in \text{Mon}_{\text{Ass}}^\mathcal{K}(\hat{\mathcal{C}}_{\infty})^\otimes \) if and only if each of the underlying \( \infty \)-categories \( \mathcal{C}_i \) admits \( \mathcal{K} \)-indexed colimits, and the tensor product functors \( \mathcal{C}_i \times \mathcal{C}_i \to \mathcal{C}_i \) preserve \( \mathcal{K} \)-indexed colimits separately in each variable.

2. Let \( F : (\mathcal{C}^\otimes_1, \ldots, \mathcal{C}^\otimes_m) \to (\mathcal{D}^\otimes_1, \ldots, \mathcal{D}^\otimes_n) \) be a morphism in \( \text{Mon}_{\text{Ass}}(\hat{\mathcal{C}}_{\infty})^\otimes \) covering a map \( \alpha : \langle m \rangle \to \langle n \rangle \) in \( \text{Fin}_{\mathcal{K}} \), where the objects \( (\mathcal{C}^\otimes_1, \ldots, \mathcal{C}^\otimes_m) \) and \( (\mathcal{D}^\otimes_1, \ldots, \mathcal{D}^\otimes_n) \) belong to \( \text{Mon}_{\text{Ass}}^\mathcal{K}(\hat{\mathcal{C}}_{\infty})^\otimes \). Then \( F \) belongs to \( \text{Mon}_{\text{Ass}}^\mathcal{K}(\hat{\mathcal{C}}_{\infty})^\otimes \) if and only if the induced functor \( \prod_{\alpha(i) = j} \mathcal{C}_i \to \mathcal{D}_j \) preserves \( \mathcal{K} \)-indexed colimits separately in each variable, for \( 1 \leq j \leq n \).

We let \( \hat{\mathcal{C}}_{\text{Mod}}(\mathcal{K})^\otimes \) denote the subcategory of \( \hat{\mathcal{C}}_{\text{Mod}}^\otimes \) described as follows:
4.8. TENSOR PRODUCTS OF $\infty$-CATEGORIES

(1') Let $C$ be an object of $\text{Cat}^{\text{Mod}}_{\infty} \times$, corresponding to a finite sequence $((\mathcal{C}_1 \otimes M_1), \ldots, (\mathcal{C}_n \otimes M_n))$. Then $C \in \text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\otimes$ if and only if each $\mathcal{C}_i$ and each $M_i$ admit $\mathcal{K}$-indexed colimits, and the tensor product functors

$$\mathcal{C}_i \times \mathcal{C}_i \rightarrow \mathcal{C}_i \quad \mathcal{C}_i \times M_i \rightarrow M_i$$

preserves $\mathcal{K}$-indexed colimits separately in each variable.

(2') Let $F : ((\mathcal{C}_1 \otimes M_1), \ldots, (\mathcal{C}_n \otimes M_n)) \rightarrow ((\mathcal{D}_1 \otimes N_1), \ldots, (\mathcal{D}_n \otimes N_n))$ be a morphism in $\text{Cat}^{\text{Mod}}_{\infty}$ covering a map $\alpha : m \rightarrow n$ in $\text{Fin}_\infty$, where the objects $((\mathcal{C}_1 \otimes M_1), \ldots, (\mathcal{C}_n \otimes M_n))$ and $((\mathcal{D}_1 \otimes N_1), \ldots, (\mathcal{D}_n \otimes N_n))$ belong to $\text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})$. Then $F$ belongs to $\text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\otimes$ if and only if the induced functors

$$\prod_{\alpha(i) = j} \mathcal{C}_i \rightarrow \mathcal{D}_j \quad \prod_{\alpha(i) = j} M_i \rightarrow N_j$$

preserves $\mathcal{K}$-indexed colimits separately in each variable, for $1 \leq j \leq n$.

We let $\text{Cat}^{\text{Alg}}(\mathcal{K})^\otimes$ denote the fiber product $(\text{Cat}^{\text{Alg}}_{\infty}) \times \times_{\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})} \times_{\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})} \times$.

Remark 4.8.5.15. Assume that $\mathcal{K}$ consists entirely of sifted simplicial sets (this is satisfied, for example, if $\mathcal{K} = \{N(\Delta)^{op}\}$). Then we can identify $\text{Cat}^{\text{Alg}}(\mathcal{K})^\otimes$, $\text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\otimes$, and $\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})^\otimes$ with $\text{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})^\times$, $\text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\times$, and $\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})^\times$, respectively.

Theorem 4.8.5.16. Let $\mathcal{K}$ be a small collection of simplicial sets. Then:

1. The map $\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})^\otimes \rightarrow N(\text{Fin}_\infty)$ determines a symmetric monoidal structure on $\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})$, and the maps $\text{Cat}^{\text{Alg}}_{\infty}(\mathcal{K}) \rightarrow \text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})^\otimes \rightarrow \text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\otimes$ are coCartesian fibrations of symmetric monoidal $\infty$-categories.

2. The functor $\Theta : \text{Cat}^{\text{Alg}}(\{N(\Delta)^{op}\}) \rightarrow \text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\otimes \rightarrow \text{Cat}^{\text{Alg}}_{\infty}(\mathcal{K})^\otimes \rightarrow \text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\otimes$ preserves products, and therefore induces a symmetric monoidal functor $\Theta^\times : \text{Cat}^{\text{Alg}}(\{N(\Delta)^{op}\})^\times \rightarrow \text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\times$.

3. Assume that $N(\Delta)^{op} \in \mathcal{K}$. Then the functor $\Theta^\times$ of (2) restricts to a functor $\Theta^\times : \text{Cat}^{\text{Alg}}(\mathcal{K})^\otimes \rightarrow \text{Cat}^{\text{Mod}}_{\infty}(\mathcal{K})^\otimes$ (see Remark 4.8.5.15).

4. The functor $\Theta^\otimes$ is symmetric monoidal.

Remark 4.8.5.17. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category which admits geometric realizations of simplicial objects, and assume that the tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$ preserves geometric realizations of simplicial objects. Let Morita($\mathcal{C}$) be the Morita $\infty$-category of $\mathcal{C}$ (see Remark 4.8.4.9). Then $\mathcal{K} = \{N(\Delta)^{op}\}$, and regard $\text{Mod}_{\mathcal{C}}(\text{Cat}_{\infty}(\mathcal{K}))$ as a symmetric monoidal $\infty$-category. It follows from Theorem 4.8.5.16, that the construction $A \mapsto \text{RMod}_{\mathcal{A}}(\mathcal{C})$ determines a symmetric monoidal functor from $\text{Alg}(\mathcal{C})$ to $\text{Mod}_{\mathcal{C}}(\text{Cat}_{\infty}(\mathcal{K}))$. It follows that the essential image $\text{Morita}(\mathcal{C}) \subseteq \text{Mod}_{\mathcal{C}}(\text{Cat}_{\infty}(\mathcal{K}))$ of this functor contains the unit object and is closed under tensor products, and therefore inherits the structure of a symmetric monoidal $\infty$-category. In particular, the construction $A \mapsto \text{RMod}_{\mathcal{A}}(\mathcal{C})$ determines a symmetric monoidal functor from $\text{Alg}(\mathcal{C})$ to $\text{Morita}(\mathcal{C})$.

Remark 4.8.5.18. Let $\mathcal{C}$ be as in Remark 4.8.5.17. Then every algebra object $A \in \text{Alg}(\mathcal{C})$ is dualizable when viewed as an object of $\text{Morita}(\mathcal{C})$. The dual of $A$ can be identified with the opposite algebra $A^{rev}$, with a duality datum given by the evaluation module $A^e \in \text{A}_{\mathcal{C}}\text{A}^{rev}\text{BMod}_{\mathcal{I}}(\mathcal{C})$, regarded as a morphism from $A \otimes A^{rev}$ to $\mathbf{1}$ in $\text{Morita}(\mathcal{C})$ (this follows from Proposition 4.6.3.12). This is a special case of Remark 4.8.4.8.

Proof of Theorem 4.8.5.16. We first prove (1). Recall that $\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})$ can be identified with the $\infty$-category $\text{Alg}(\text{Cat}_{\infty})$ of associative algebra objects of $\text{Cat}_{\infty}$ (Proposition 2.4.2.5). Here we regard $\text{Cat}_{\infty}$ as endowed with the Cartesian symmetric monoidal structure. The $\infty$-category $\text{Alg}(\text{Cat}_{\infty})$ inherits a symmetric monoidal structure from that of $\text{Cat}_{\infty}$ (see Example 3.2.4.4), which is also Cartesian: we therefore obtain an identification $\text{Alg}(\text{Cat}_{\infty})^\otimes \simeq \text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})^\times$. Under this equivalence, the subcategory $\text{Mon}_{\text{Ass}}(\text{Cat}_{\infty})^\otimes$
corresponds to the subcategory \( \text{Alg}(\text{Cat}_\infty(K))^\circ \), which is again a symmetric monoidal \( \infty \)-category. A similar argument shows that \( \text{Cat}_\infty^K(A)^\circ \to \text{Alg}(\text{Cat}_\infty(K))^\circ \) is a coCartesian fibration of symmetric monoidal \( \infty \)-categories. Finally, we observe that the functor \( \text{Cat}_\infty^K(A)^\circ \to \text{Mon}_A^K(\text{Cat}_\infty)^\circ \) is a pullback of \( (\text{Cat}_A^K)^\circ \to \text{Mon}_A^K(\text{Cat}_\infty)^\circ \), which is easily seen to be a coCartesian fibration of \( \infty \)-operads. This proves (1).

Assertion (2) is obvious, and assertion (3) follows from Corollary 4.2.3.5. We will prove (4). It is easy to see that \( \Theta^\circ \) is a map of \( \infty \)-operads, and it follows from Proposition 4.2.4.9 that \( \Theta^\circ \) preserves unit objects. Consequently, it will suffice to show that for every pair of objects \((\mathcal{C}, A), (\mathcal{D}, B) \in \text{Cat}_\infty^K(K)\), the induced map

\[
\Theta(\mathcal{C}, A) \otimes \Theta(\mathcal{D}, B) \to \Theta((\mathcal{C} \otimes A) \otimes (\mathcal{D} \otimes B))
\]

is an equivalence in \( \text{Cat}_\infty^K(K) \). In other words, we wish to show that \( \Theta \) induces an equivalence of \( \infty \)-categories

\[
\theta : \text{RMod}_A(\mathcal{C})\otimes \text{RMod}_B(\mathcal{D}) \to \text{RMod}_{A \otimes B}(\mathcal{C} \otimes \mathcal{D})
\]

(here the tensor products are taken in \( \text{Cat}_\infty^K(K) \)). We have a homotopy commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\text{RMod}_A(\mathcal{C})\otimes \text{RMod}_B(\mathcal{D}) & \xrightarrow{\theta} & \text{RMod}_{A \otimes B}(\mathcal{C} \otimes \mathcal{D}) \\
\downarrow{G} & & \downarrow{G} \\
\mathcal{C} \otimes \mathcal{D}.
\end{array}
\]

To prove that \( \theta \) is a categorical equivalence, it will suffice to show that this diagram satisfies the hypotheses of Corollary 4.7.4.16:

(a) The \( \infty \)-categories \( \text{RMod}_A(\mathcal{C})\otimes \text{RMod}_B(\mathcal{D}) \) and \( \text{RMod}_{A \otimes B}(\mathcal{C} \otimes \mathcal{D}) \) admit geometric realizations of simplicial objects. This follows from our assumption that \( N(\Delta)^{op} \in K \).

(b) The functors \( G \) and \( G' \) admit left adjoints, which we will denote by \( F \) and \( F' \). The existence of \( F' \) is guaranteed by Proposition 4.2.4.2, and is given informally by the formula \( X \mapsto X \otimes (A \otimes B) \). Similarly, Proposition 4.2.4.2 guarantees that the forgetful functors \( \text{RMod}_A(\mathcal{C}) \to \mathcal{C} \) and \( \text{RMod}_B(\mathcal{D}) \to \mathcal{D} \) admit left adjoints, given by tensoring on the right with \( A \) and \( B \), respectively. The tensor product of these left adjoints is a left adjoint to \( G \).

(c) The functor \( G' \) is conservative and preserves geometric realizations of simplicial objects. The first assertion follows from Corollary 4.2.3.2 and the second from Corollary 4.2.3.5.

(d) The functor \( G \) is conservative and preserves geometric realizations of simplicial objects. The second assertion is obvious: \( G \) is a tensor product of the forgetful functors \( \text{RMod}_A(\mathcal{C}) \to \mathcal{C} \) and \( \text{RMod}_B(\mathcal{D}) \to \mathcal{D} \), each of which preserves geometric realizations (and can therefore be interpreted as a morphism in \( \text{Cat}_\infty(K) \)) by Corollary 4.2.3.5. To prove that \( G \) is conservative, we factor \( G \) as a composition

\[
\text{RMod}_A(\mathcal{C})\otimes \text{RMod}_B(\mathcal{D}) \xrightarrow{G_0} \mathcal{C} \otimes \text{RMod}_B(\mathcal{D}) \xrightarrow{G_1} \mathcal{C} \otimes \mathcal{D}.
\]

We can identify \( G_1 \) with the forgetful functor

\[
(\mathcal{C} \otimes \mathcal{D}) \otimes \mathcal{D} \to (\mathcal{C} \otimes \mathcal{D}) \otimes \mathcal{D} \simeq \mathcal{C} \otimes \mathcal{D}.
\]

Theorem 4.8.4.6 allows us to identify the left hand side with the \( \infty \)-category \( \text{RMod}_B(\mathcal{C} \otimes \mathcal{D}) \). Under this identification, \( G_1 \) corresponds to the forgetful functor \( \text{RMod}_B(\mathcal{C} \otimes \mathcal{D}) \to \mathcal{C} \otimes \mathcal{D} \), which is conservative by Corollary 4.2.3.2. A similar arguments shows that \( G_0 \) is conservative, so that \( G \simeq G_1 \circ G_0 \) is conservative as required.

(e) The canonical natural transformation \( G' \circ F' \to G \circ F \) is an equivalence of functors from \( \mathcal{C} \otimes \mathcal{D} \) to itself. This is clear from the descriptions of \( F \) and \( F' \) given above: both compositions are given by right multiplication by the object \( A \otimes B \in \mathcal{C} \otimes \mathcal{D} \).
Remark 4.8.5.19. Fix a small collection of simplicial sets $\mathcal{K}$ which contains $N(\Delta)^{op}$. Let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{C}$ admits $\mathcal{K}$-indexed colimits and that the tensor product $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves $\mathcal{K}$-indexed colimits separately in each variable. Then we $\mathcal{C}^\otimes$ as a commutative algebra object in the (symmetric monoidal) $\infty$-category $\text{Mon}_{\mathcal{K}}(\text{Cat}_\infty)$. The following conditions are satisfied:

1. $\mathcal{C}^\otimes$ is unital, the vertical maps are categorical equivalences, so that $\theta$ is fully faithful.
2. Since $\mathcal{O}^\otimes$ is unital, the vertical maps are categorical equivalences, so that $\theta$ is fully faithful.

Corollary 4.8.5.20. Let $\mathcal{K}$ and $\mathcal{C}^\otimes$ be as in Remark 4.8.5.19, and let $\mathcal{O}^\otimes$ be a unital $\infty$-operad. Then the functor $\Theta^\otimes_\mathcal{C}$ induces a fully faithful functor

$$
\theta : \text{Alg}_\mathcal{O}(\text{Alg}(\mathcal{C})) \to \text{Alg}_\mathcal{O}(\text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K}))).
$$

Proof. Let $\text{Alg}(\mathcal{C})^\otimes$ and $\text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K}))^\otimes$ be unitalizations of $\text{Alg}(\mathcal{C})^\otimes$ and $\text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K}))^\otimes$, respectively (see §2.3.1; note that $\text{Alg}(\mathcal{C})^\otimes$ is already a unital $\infty$-operad, so that $\text{Alg}(\mathcal{C})^\otimes \simeq \text{Alg}(\mathcal{C})^\otimes$). The functor $\Theta^\otimes_\mathcal{C}$ induces a symmetric monoidal functor $\text{Alg}(\mathcal{C})^\otimes \to \text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K}))^\otimes$, and Theorem 4.8.5.5 guarantees that this functor is fully faithful. We have a commutative diagram

$$
\begin{array}{ccc}
\text{Alg}_\mathcal{O}(\text{Alg}(\mathcal{C})) & \xrightarrow{\theta^*} & \text{Alg}_\mathcal{O}(\text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K}))) \\
\downarrow & & \downarrow \\
\text{Alg}_\mathcal{O}(\text{Alg}(\mathcal{C})) & \xrightarrow{\theta} & \text{Alg}_\mathcal{O}(\text{LMod}_{\mathcal{C}}(\text{Cat}_\infty(\mathcal{K})))
\end{array}
$$

where $\theta^*$ is fully faithful. Since $\mathcal{O}^\otimes$ is unital, the vertical maps are categorical equivalences, so that $\theta$ is fully faithful as well.

Corollary 4.8.5.21. Let $\mathcal{K}$ be a class of simplicial sets which includes $N(\Delta)^{op}$. Let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category which admits $\mathcal{K}$-indexed colimits, for which the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves $\mathcal{K}$-indexed colimits separately in each variable. Then the construction $A \mapsto \text{Mod}_A(\mathcal{C})^\otimes$ determines a fully faithful embedding

$$
\theta : \text{CAlg}(\mathcal{C}) \to \text{CAlg}(\text{Cat}_\infty(\mathcal{K}))^\otimes.
$$

Moreover, a symmetric monoidal functor $F : \mathcal{C}^\otimes \to \mathcal{D}^\otimes$ belongs to the essential image of $\theta$ if and only if the following conditions are satisfied:

1. The $\infty$-category $\mathcal{D}$ admits $\mathcal{K}$-indexed colimits, the tensor product $\otimes : \mathcal{D} \times \mathcal{D} \to \mathcal{D}$ preserves $\mathcal{K}$-indexed colimits separately in each variable.
2. The functor $F$ admits a right adjoint $G$ (this condition guarantees that $F$ preserves $\mathcal{K}$-indexed colimits).
3. The functor $G$ preserves geometric realizations of simplicial objects.
4. The functor $G$ is conservative.
5. For every object $C \in \mathcal{C}$ and $D \in \mathcal{D}$, the canonical map

$$
C \otimes G(D) \to G(F(C) \otimes D)
$$

is an equivalence.
Proof. Since $\mathcal{A}$ is a unital $\infty$-operad, Propositions 3.2.4.10 and 2.4.3.9 imply that the unique bifunctor of $\infty$-operads $\mathcal{A} \times \text{Comm} \to \text{Comm}$ exhibits $\text{Comm}$ as a tensor product of $\mathcal{A}$ and $\text{Comm}$. Corollary 4.8.5.20 yields a fully faithful embedding $\text{CAlg}(\mathcal{C}) \to \text{CAlg}(\text{LMod}_\mathcal{C}(\text{Cat}_\infty(\mathcal{K})))$. The functor $\theta$ is obtained by composing this embedding with the equivalence

$$\text{CAlg}(\text{LMod}_\mathcal{C}(\text{Cat}_\infty(\mathcal{K}))) \simeq \text{CAlg}(\text{Cat}_\infty(\mathcal{K}))_{\mathcal{C}}$$

furnished by Proposition 3.4.1.3. The description of the essential image of $\theta$ follows from Proposition 4.8.5.8.

Corollary 4.8.5.22. Let $\mathcal{K}$ and $\mathcal{C}$ be as in Remark 4.8.5.19. Then the functor $\Theta_{\mathcal{C}}^\mathcal{C}$ induces a fully faithful functor $\text{CAlg}(\mathcal{C}) \to \text{CAlg}(\text{Mod}_\mathcal{C}(\text{Cat}_\infty(\mathcal{K})))$. 

\[
\]
Chapter 5

Little Cubes and Factorizable Sheaves

Let $X$ be a topological space equipped with a base point $\ast$. We let $\Omega X$ denote the loop space of $X$, which we will identify with the space of continuous map $p : [-1, 1] \to X$ such that $f(-1) = \ast = f(1)$. Given a pair of loops $p, q \in \Omega X$, we can define a composite loop $p \circ q$ by concatenating $p$ with $q$: that is, we define $p \circ q : [-1, 1] \to X$ by the formula

$$(p \circ q)(t) = \begin{cases} 
q(2t + 1) & \text{if } -1 \leq t \leq 0 \\
p(2t - 1) & \text{if } 0 \leq t \leq 1.
\end{cases}$$

This composition operation is associative up to homotopy, and endows the set of path components $\pi_0 \Omega X$ with the structure of a group: namely, the fundamental group $\pi_1(X, \ast)$. However, composition of paths is not strictly associative: given a triple of paths $p,q,r \in \Omega X$, we have

$$(p \circ (q \circ r))(t) = \begin{cases} 
r(4t + 3) & \text{if } -1 \leq t \leq -\frac{1}{2} \\
q(4t + 1) & \text{if } -\frac{1}{2} \leq t \leq 0 \\
p(2t - 1) & \text{if } 0 \leq t \leq 1.
\end{cases} \quad (\ast)$$

$$(p \circ q \circ r)(t) = \begin{cases} 
r(2t + 1) & \text{if } -1 \leq t \leq 0 \\
q(4t - 1) & \text{if } 0 \leq t \leq \frac{1}{2} \\
p(4t - 3) & \text{if } \frac{1}{2} \leq t \leq 1.
\end{cases} \quad (\ast)$$

The paths $p \circ (q \circ r)$ and $(p \circ q) \circ r$ follow the same trajectories but are parametrized differently; they are homotopic but not identical.

One way to compensate for the failure of strict associativity is to consider not one composition operation but several. For every finite set $S$, let $\text{Rect}((-1,1) \times S, (-1,1))$ denote the collection of finite sequences of maps $\{f_s : (-1,1) \to (-1,1)\}_{s \in S}$ with the following properties:

1. For $s \neq t$, the maps $f_s$ and $f_t$ have disjoint images.
2. For each $s \in S$, the map $f_s$ is given by a formula $f_s(t) = at + b$ where $a > 0$.

If $X$ is any pointed topological space, then there is an evident map

$$\theta : (\Omega X)^S \times \text{Rect}((-1,1) \times S, (-1,1)) \to \Omega X,$$

given by the formula

$$\theta(p_s)_{s \in S}, \{f_s\}_{s \in S})(t) = \begin{cases} 
p_s(t') & \text{if } t = f_s(t') \\
\ast & \text{otherwise.}
\end{cases}$$

Each of the spaces $\text{Rect}((-1,1) \times S, (-1,1))$ is equipped with a natural topology (with respect to which the map $\theta$ is continuous), and the collection of spaces $\{	ext{Rect}((-1,1) \times S, (-1,1))\}_{S}$ can be organized into a topological operad, which we will denote by $\mathcal{E}_1$. We can summarize the situation as follows:
Every point of $\text{Rect}((-1,1) \times S, (-1,1))$ determines a linear ordering of the finite set $S$. Conversely, if we fix a linear ordering of $S$, then the corresponding subspace of $\text{Rect}((-1,1) \times S, (-1,1))$ is contractible. In other words, there is a canonical homotopy equivalence of $\text{Rect}((-1,1) \times S, (-1,1))$ with the (discrete) set of linear orderings of $S$. Together, these homotopy equivalences determine a weak equivalence of the topological operad $\mathcal{E}_1$ with the associative operad (Definition 4.1.1.1). Consequently, an action of the operad $\mathcal{E}_1$ can be regarded as a homotopy-theoretic substitute for an associative algebra structure. In other words, assertion (⋆) articulates the idea that the loop space $\Omega X$ is equipped with a multiplication which associative up to coherent homotopy.

If $X$ is a pointed space, then we can consider also the $k$-fold loop space $\Omega^k X$, which we will identify with the space of all maps $f : [-1,1]^k \to X$ which carry the boundary of the cube $[-1,1]^k$ to the base point of $X$. If $k > 0$, then we can identify $\Omega^k X$ with $\Omega(\Omega^{k-1} X)$, so that $\Omega^k X$ is equipped with a coherently associative multiplication given by concatenation of loops. However, if $k > 1$, then the structure of $\Omega^k X$ is much richer. To investigate this structure, it is convenient to introduce a higher-dimensional version of the topological $\mathcal{E}_1$ operad, the little $k$-cubes operad introduced by Boardman and Vogt ([19]). In §5.1, we will review the definition of this topological operad and study the properties of its operadic nerve, which we denote by $E^k_\infty$ and refer to as the $\infty$-operad of little $k$-cubes.

If the pointed space $X$ is $k$-connective, then one can show that the passage from $X$ to $\Omega^k X$ involves no loss of information provided we regard $\Omega^k X$ as an algebra over the $\infty$-operad $E^k_\infty$. More precisely, we can recover $X$ (up to weak homotopy equivalence) by applying an iterated bar construction to $\Omega^k X$. We will prove this in §5.2 (see Theorems 5.2.6.10 and 5.2.6.15) after making a detailed study of the bar construction and its iterates.

Though the $\infty$-operads $E^k_\infty$ were originally introduced for the study of iterated loop spaces, they arise naturally in many other contexts. When $k = 1$, the $\infty$-operad $E^1_\infty$ is equivalent to the associative $\infty$-operad $\text{Ass}_\infty$ (Example 5.1.0.7), which we have studied extensively in Chapter 4. Associative algebras are ubiquitous throughout mathematics, due largely to the fact that for any object $V$ of any symmetric monoidal category (or $\infty$-category) $\mathcal{C}$, the endomorphism object $\text{End}(V) \in \mathcal{C}$ (if it exists) has the structure of an associative algebra (see §4.7.2). In §5.3, we will study a higher categorical analogue of the same phenomenon: under mild hypotheses on $\mathcal{C}$, one can associate to each $E_k$-algebra $A \in \text{Alg}_{E_k}(\mathcal{C})$ a center $Z_{E_k}(A)$, which is an $E_{k-1}$-algebra object of $\mathcal{C}$. As an application, we include a proof of Deligne’s conjecture that the Hochschild cochain complex of any associative algebra carries an action of the little 2-cubes $\infty$-operad $E^2_\infty$.

The structure of the $\infty$-operad $E^k_\infty$ is closely related to topology of manifolds. If $M$ is a $k$-dimensional topological manifold, then we can associate to $M$ an $\infty$-operad $E^k_\infty$, which is equivalent to $E^k_\infty$ in the special case where $M \simeq \mathbb{R}^k$ is a Euclidean space. If $\mathcal{C}$ is a symmetric monoidal $\infty$-category, then the (nonunital) $E_M$-algebra objects of $\mathcal{C}$ can be equipped with factorizable cosheaves on $M$ with values in $\mathcal{C}$ (Theorem 5.5.4.10). In §5.5, we will discuss the notion of factorizable cosheaf together with the closely related theory of topological chiral homology. Our discussion makes use of a general construction which produces variants of the $\infty$-operad $E^k_\infty$, which we discuss in §5.4.

### 5.1 Definitions and Basic Properties

Our goal in this section is to study the $\infty$-categorical avatar of the little $k$-cubes operads introduced by Boardman and Vogt. We begin with some definitions.

**Definition 5.1.0.1.** Fix an integer $k \geq 0$. We let $[k] = (-1,1]^k$ denote an open cube of dimension $k$. We will say that a map $f : [k] \to [k]$ is a rectilinear embedding if it is given by the formula

$$f(x_1, \ldots, x_k) = (a_1 x_1 + b_1, \ldots, a_k x_k + b_k)$$
5.1. DEFINITIONS AND BASIC PROPERTIES

for some real constants $a_i$ and $b_i$, with $a_i > 0$. More generally, if $S$ is a finite set, then we will say that a map $\Box^k \times S \to \Box^k$ is a rectilinear embedding if it is an open embedding whose restriction to each connected component of $\Box^k \times S$ is rectilinear. Let $\text{Rect}(\Box^k \times S, \Box^k)$ denote the collection of all rectilinear embeddings from $\Box^k \times S$ into $\Box^k$. We will regard $\text{Rect}(\Box^k \times S, \Box^k)$ as a topological space (it can be identified with an open subset of $(R^{2k})^S$).

The spaces $\text{Rect}(\Box^k \times \{1, \ldots, n\}, \Box^k)$ constitute the $n$-ary operations of a topological operad, which we will denote by $t^k E_k$ and refer to as the little $k$-cubes operad.

**Definition 5.1.0.2.** We define a topological category $t^k E_k^\circ$ as follows:

1. The objects of $t^k E_k^\circ$ are the objects $\langle n \rangle \in \text{Fin}_*.$
2. Given a pair of objects $\langle m \rangle, \langle n \rangle \in t^k E_k^\circ$, a morphism from $\langle m \rangle$ to $\langle n \rangle$ in $t^k E_k^\circ$ consists of the following data:
   - A morphism $\alpha : \langle m \rangle \to \langle n \rangle$ in $\text{Fin}_*$.
   - For each $j \in \langle n \rangle^o$ a rectilinear embedding $\Box^k \times \alpha^{-1}\{j\} \to \Box^k$.
3. For every pair of objects $\langle m \rangle, \langle n \rangle \in t^k E_k^\circ$, we regard $\text{Hom}_{t^k E_k^\circ}(\langle m \rangle, \langle n \rangle)$ as endowed with the topology induced by the presentation
   $$\text{Hom}_{t^k E_k^\circ}(\langle m \rangle, \langle n \rangle) = \coprod_{f : \langle m \rangle \to \langle n \rangle} \prod_{1 \leq j \leq n} \text{Rect}(\Box^k \times f^{-1}\{j\}, \Box^k).$$
4. Composition of morphisms in $t^k E_k^\circ$ is defined in the obvious way.

We let $E_k^\circ$ denote the nerve of the topological category $t^k E_k^\circ$.

Corollary T.1.1.5.12 implies that $E_k^\circ$ is an $\infty$-category. There is an evident forgetful functor from $t^k E_k^\circ$ to the (discrete) category $\text{Fin}_*$, which induces a functor $E_k^\circ \to N(\text{Fin}_*)$.

**Proposition 5.1.0.3.** The functor $E_k^\circ \to N(\text{Fin}_*)$ exhibits $E_k^\circ$ as an $\infty$-operad.

**Proof.** We have a canonical isomorphism $E_k^\circ \simeq N^\circ(\mathcal{O})$, where $\mathcal{O}$ denotes the simplicial colored operad having a single object $\Box^k$ with $\text{Mul}_0((\Box^k)_{i \in I}, \Box^k) = \text{Sing} \text{Rect}(\Box^k \times I, \Box^k)$. Since $\mathcal{O}$ is a fibrant simplicial colored operad, $E_k^\circ$ is an $\infty$-operad by virtue of Proposition 2.1.1.27. □

**Definition 5.1.0.4.** We will refer to the $\infty$-operad $E_k^\circ$ as the $\infty$-operad of little $k$-cubes.

**Remark 5.1.0.5.** Let $\text{Env}(E_k)^\circ$ be the symmetric monoidal envelope of $E_k^\circ$, as defined in §2.2.4. We can describe the underlying $\infty$-category $\text{Env}(E_k)$ informally as follows: its objects are topological spaces of the form $\coprod_{i \in I} \Box^k$, and its morphisms are given by embeddings which are rectilinear on each component. The symmetric monoidal structure on $\text{Env}(E_k)$ is given by disjoint union.

**Example 5.1.0.6.** Suppose that $k = 0$. Then $\Box^k$ consists of a single point, and the only rectilinear embedding from $\Box^k$ to itself is the identity map. A finite collection $\{f_i : \Box^k \to \Box^k\}_{i \in I}$ of rectilinear embeddings have disjoint images if and only if the index set $I$ has at most one element. It follows that $t^k E_k$ is isomorphic (as a topological category) to the subcategory of $\text{Fin}_*$ spanned by the injective morphisms in $\text{Fin}_*$. We conclude that $E_k^\circ$ is isomorphic to the $\infty$-operad $E_0^\circ \subseteq N(\text{Fin}_*)$ introduced in Example 2.1.1.19.

**Example 5.1.0.7.** Suppose that $k = 1$, so that we can identify the cube $\Box^k$ with the interval $(-1, 1)$. Every rectangular embedding $(-1, 1) \times I \to (-1, 1)$ determines a linear ordering of the set $I$, where $i < j$ if and only if $f(t, i) < f(t', j)$ for all $t, t' \in (-1, 1)$. This construction determines a decomposition of the space $\text{Rect}((-1, 1) \times I, (-1, 1))$ into components $\text{Rect}_<( (-1, 1) \times I, (-1, 1))$, where $<$ ranges over all linear orderings on $I$. Each of the spaces $\text{Rect}_<( (-1, 1) \times I, (-1, 1))$ can be realized as a nonempty convex subset
of \((R^2)^1\) and is therefore contractible. It follows that \(\text{Rect}((-1, 1) \times I, (-1, 1))\) is homotopy equivalent to the discrete set of all linear orderings on \(I\).

Using these homotopy equivalences, we obtain a weak equivalence of topological categories \(\mathsf{E}_k^\otimes \to \mathsf{Ass}^\otimes\), where \(\mathsf{Ass}^\otimes\) is the category of Definition 4.1.1.3. Passing to the homotopy coherent nerves, we obtain an equivalence of \(\infty\)-operads \(\mathsf{E}_k^\otimes \simeq \mathsf{Ass}^\otimes\).

Example 5.1.0.7 implies that, when \(k = 1\), the theory of \(\mathsf{E}_k\)-algebras reduces to the theory of associative algebras studied in Chapter 4. The \(\infty\)-operads \(\mathsf{E}_k^\otimes\) have a related interpretation when \(k > 1\): namely, giving an \(\mathsf{E}_k\)-algebra object of a symmetric monoidal \(\infty\)-category \(\mathcal{C}\) is equivalent to giving an object \(A \in \mathcal{C}\) which is equipped with \(k\) different associative multiplications, which are compatible with one another in a suitable sense. This is a consequence of Theorem 5.1.2.2, which asserts that for \(k, k' \geq 0\) we can identify \(\mathsf{E}_k^\otimes_{k+k'}\) with the tensor product of the \(\infty\)-operads \(\mathsf{E}_k^\otimes\) and \(\mathsf{E}_{k'}^\otimes\). We will prove this result in §5.1.2.

If \(X\) is a pointed topological space, then the \(k\)-fold loop space \(\Omega^k X\) carries an action of the topological operad \(\mathsf{E}_k\). This observation admits the following converse, which highlights the importance of the operads \(\mathsf{E}_k\) in algebraic topology:

**Theorem 5.1.0.8** (May). Let \(Y\) be a topological space equipped with an action of the little cubes operad \(\mathsf{E}_k\).

If \(k > 0\), assume that \(\pi_0 Y\) is a group under the induced monoid structure (see Definition 5.2.6.6). Then \(Y\) is weakly homotopy equivalent to \(\Omega^k X\), for some pointed topological space \(X\).

In §5.2.6, we will prove a variant of this result, which describes \(\mathsf{E}_k\)-algebra objects of the \(\infty\)-category \(\mathcal{S}\) of spaces (see Theorem 5.2.6.15). Theorem 5.1.0.8 can be interpreted as saying that, in some sense, the \(\infty\)-operad \(\mathsf{E}_k\) encodes precisely the structure that a \(k\)-fold loop space should be expected to possess. In the case \(k = 1\), we recover a familiar notion: namely, a (coherently) associative multiplication. This makes sense in a variety of contexts outside of algebraic topology. For example, one can consider associative algebra objects in the category of abelian groups (that is, associative rings), or more generally associative algebras in any monoidal \(\infty\)-category (as in Chapter 4). A similar phenomenon occurs for larger values of \(k\): that is, it is interesting to study algebras over the topological operads \(\mathsf{E}_k\) in categories other than the category of topological spaces. For example, the theory of *structured ring spectra* (which is the subject of Chapter 7) is obtained by considering \(\mathsf{E}_k\)-algebras in the setting of spectra.

For algebraic applications, it is important to consider not only \(\mathsf{E}_k\)-algebras but also modules over them. Here the essential observation is that the \(\infty\)-operads \(\mathsf{E}_k^\otimes\) are coherent, so that the general theory of Chapter 3 gives a robust theory of modules. We will prove this coherence result in §5.1.1, using some general observations relating the spaces of operations in \(\mathsf{E}_k^\otimes\) to configuration spaces of points on manifolds. It follows that for every \(\mathsf{E}_k\)-algebra object \(A\) of a sufficiently nice symmetric monoidal \(\infty\)-category \(\mathcal{C}\), we can define an \(\infty\)-category \(\text{Mod}_{\mathsf{E}_k}^\otimes(\mathcal{C})\) which is equipped with an \(\mathsf{E}_k\)-monoidal structure. In §5.1.3, we will show that the tensor product in \(\text{Mod}_{\mathsf{E}_k}^\otimes(\mathcal{C})\) can be described in terms of the relative tensor product over \(A\) which was studied in §4.4. In §5.1.4, we will show that (if \(k > 0\)) the \(\infty\)-category \(\text{RMod}_{\mathsf{A}}(\mathcal{C})\) inherits the structure of an \(\mathsf{E}_{k-1}\)-monoidal \(\infty\)-category, and that there is an \(\mathsf{E}_{k-1}\)-monoidal forgetful functor \(\text{Mod}_{\mathsf{E}_k}^\otimes(\mathcal{C}) \to \text{RMod}_{\mathsf{A}}(\mathcal{C})\) (Theorem 5.1.4.10).

### 5.1.1 Little Cubes and Configuration Spaces

Our main goal in this section is to prove the following result:

Let \(k\) be a nonnegative integer and let \(\mathsf{E}_k^\otimes\) be the \(\infty\)-operad of little \(k\)-cubes introduced in Definition 5.1.0.2. If \(k = 1\), then \(\mathsf{E}_k^\otimes\) is equivalent to the associative \(\infty\)-operad \(\mathsf{Ass}^\otimes\) (Example 5.1.0.7), which is coherent by Proposition 4.1.1.16. Our ultimate goal in this section is to prove that this is general phenomenon:

**Theorem 5.1.1.1.** Let \(k \geq 0\) be a nonnegative integer. Then the little cubes \(\infty\)-operad \(\mathsf{E}_k^\otimes\) is coherent.

In order to prove Theorem 5.1.1.1, we will need a good understanding of the spaces of operations in the \(\infty\)-operad \(\mathsf{E}_k^\otimes\). By construction, these can be realized as spaces of rectilinear embeddings between cubes. However, for many purposes it is convenient to replace these embedding spaces by configuration spaces.
5.1. DEFINITIONS AND BASIC PROPERTIES

Definition 5.1.1.2. Let $I$ be a finite set and let $M$ be a topological manifold. We let $\text{Conf}(I; M)$ denote the space of all injective maps from $I$ into $M$, which we identify with a subspace of $M^I$. We refer to $\text{Conf}(I; M)$ as the configuration space of maps $I \to M$.

Lemma 5.1.1.3. Let $I$ and $J$ be finite sets, and suppose we are given an injective map $p: J \to \square^k$. Let $\square^k \subseteq \text{Rect}(\square^k \times (I \coprod J), \square^k)$ be the open subset consisting of those rectilinear embeddings $f: \square^k \times (I \coprod J) \to \square^k$ such that, for every $j \in J$, we have $p(j) \in f(\square^k \times \{j\})$. Then evaluation at the origin $0 \in \square^k$ determines a homotopy equivalence $U \to \text{Conf}(I; \square^k - p(J))$.

Proof. Let $\overline{U}$ denote the collection of all maps $\square^k \times (I \coprod J) \to \square^k$ which are homotopy equivalences:

$$\square^k \times (I \coprod J) \to J \coprod J \xrightarrow{\overline{p}} \square^k$$

where $\overline{p}$ is an injection with $\overline{p}|J = p$. Then $\theta$ factors as a composition

$$U \xrightarrow{\theta'} \overline{U} \xrightarrow{\theta''} \text{Conf}(I; \square^k - p(J))$$

where $\theta'$ is the open inclusion and $\theta''$ is given by evaluation at the origin $0 \in \square^k$. We claim that both $\theta'$ and $\theta''$ are homotopy equivalences:

(i) For every map $f \in U$, let $\epsilon(f)$ denote the infimum over $a, b \in I \coprod J$ of the distance from $f(\square^k \times \{a\})$ to $f(\square^k \times \{a\})$ and the distance from $f(\square^k \times \{a\})$ to the boundary of $\square^k$. We then define a family of maps $\{f_t\}_{t \in [0, 1]}$ by the formula

$$f_t(x_1, \ldots, x_k, i) = f(x_1, \ldots, x_k, i) + \frac{t\epsilon(f) - 2}{2k} (x_1, \ldots, x_k).$$

This construction determines a map $H: U \times [0, 1] \to \overline{U}$ such that $H|([0 \times \{0\})$ is the identity map and $H$ carries $([0 \times \{1\})$ into $U$. It follows that $H|([0 \times \{1\})$ is a homotopy inverse to $\theta'$.

(ii) There is an evident homeomorphism $\text{Conf}(I; \square^k - p(J)) \simeq U - U$, which determines a map $j: \text{Conf}(I, \square^k - p(J)) \to U$. We claim that $j$ is a homotopy equivalence. Indeed, there is a deformation retraction of $U$ onto $U - U$, which carries a map $f: \square^k \times (I \coprod J) \to \square^k$ to the family of maps $\{f_t: \square^k \times (I \coprod J) \to \square^k\}_{t \in [0, 1]}$ given by the formula

$$f_t(x_1, \ldots, x_k, a) = \begin{cases} f(tx_1, \ldots, tx_k, a) & \text{if } a \in I \\ tf(x_1, \ldots, x_k, b) + (1 - t)p(b) & \text{if } b \in J. \end{cases}$$

Since $\theta''$ is a left inverse to $j$, it follows that $\theta''$ is a homotopy equivalence. 

We can use the relationship between rectilinear embedding spaces and configuration spaces to establish some basic connectivity properties of the $\infty$-operads $\mathbb{P}_k^{\otimes}$:

Proposition 5.1.1.4. Let $k \geq 0$. For every pair of integers $m, n \geq 0$, the map of topological spaces $\text{Map}_{\mathbb{P}_k^{\otimes}}((m), (n)) \to \text{Hom}_{\mathbb{P}_k^{\otimes}}((m), (n))$ is $(k - 1)$-connective.

Proof. Unwinding the definitions, this is equivalent to the requirement that for every finite set $I$, the space of rectilinear embeddings $\text{Rect}(\square^k \times I \coprod \square^k)$ is $(k - 1)$-connective. This space is homotopy equivalent (via evaluation at the origin) to the configuration space $\text{Conf}(I; \square^k)$ of injective maps $I \to \square^k$ (Lemma 5.1.1.3). We will prove more generally that $\text{Conf}(J, \square^k - F)$ is $(k - 1)$-connective, where $J$ is any finite set and $F$ is any finite subset of $\square^k$. The proof proceeds by induction on the number of elements of $J$. If $J = \emptyset$, then $\text{Conf}(J, \square^k - F)$ consists of a single point and there is nothing to prove. Otherwise, choose an element
$j \in J$. Evaluation at $j$ determines a Serre fibration $\text{Conf}(J, \Box^k - F) \to \Box^k - F$, whose fiber over a point $x$ is the space $\text{Conf}(J - \{j\}, \Box^k - (F \cup \{x\}))$. The inductive hypothesis guarantees that these fibers are $(k - 1)$-connective. Consequently, to show that $\text{Conf}(J, \Box^k - F)$ is $(k - 1)$-connective, it suffices to show that $\Box^k - F$ is $(k - 1)$-connective. In other words, we must show that for $m < k$, every map $g_0 : S^{m-1} \to \Box^k - F$ can be extended to a map $g : D^m \to \Box^k - F$, where $D^m$ denotes the unit disk of dimension $m$ and $S^{m-1}$ its boundary sphere. Without loss of generality, we may assume that $g_0$ is smooth. Since $\Box^k$ is contractible, we can extend $g_0$ to a map $g : D^m \to \Box^k$, which we may also assume to be smooth and transverse to the submanifold $F \subseteq \Box^k$. Since $F$ has codimension $k$ in $\Box^k$, $g^{-1}F$ has codimension $k$ in $D^m$, so that $g^{-1}F = \emptyset$ (since $m < k$) and $g$ factors through $\Box^k - F$, as desired. \hfill \Box

For each $k \geq 0$, there is a stabilization functor $\mathcal{E}_k \to \mathcal{E}_{k+1}$ which is the identity on objects and is given on morphisms by taking the product with the interval $(-1,1)$. This functor induces a map of $\infty$-operads $\mathcal{E}_k^\otimes \to \mathcal{E}_{k+1}^\otimes$. Proposition 5.1.1.4 immediately implies the following:

**Corollary 5.1.1.5.** The colimit of the sequence of $\infty$-operads

$$
\mathcal{E}_0^\otimes \to \mathcal{E}_1^\otimes \to \mathcal{E}_2^\otimes \to \ldots
$$

is equivalent to the commutative $\infty$-operad $\text{Comm}^\otimes = \text{N}(\text{Fin}_*)$.

**Notation 5.1.1.6.** Motivated by Corollary 5.1.1.5, we adopt the following convention: when $k = \infty$, we let $\mathcal{E}_k^\otimes$ denote the commutative $\infty$-operad $\text{Comm}^\otimes$ (so that $\mathcal{E}_\infty^\otimes \simeq \lim_{j \geq 0} \mathcal{E}_j^\otimes$).

Consequently, if $\mathcal{E}^\otimes$ is a symmetric monoidal $\infty$-category, then the $\infty$-category $\text{CAlg}(\mathcal{E})$ of commutative algebra objects of $\mathcal{E}$ can be identified with the homotopy limit of the tower of $\infty$-categories $\{\text{Alg}_{\mathcal{E}_k}(\mathcal{E})\}_{k \geq 0}$. In many situations, this tower actually stabilizes at some finite stage:

**Corollary 5.1.1.7.** Let $\mathcal{E}^\otimes$ be a symmetric monoidal $\infty$-category. Let $n \geq 1$, and assume that the underlying $\infty$-category $\mathcal{E}$ is equivalent to an $n$-category (that is, the mapping spaces $\text{Map}_{\mathcal{E}}(X,Y)$ are $(n-1)$-truncated for every pair of objects $X,Y \in \mathcal{E}$; see §4.2.3.4). Then the map $\mathcal{E}_k^\otimes \to \text{N}(\text{Fin}_*)$ induces an equivalence of $\infty$-categories $\text{CAlg}(\mathcal{E}) \to \text{Alg}_{\mathcal{E}_k}(\mathcal{E})$ for $k > n$.

**Proof.** Let $C$ and $D$ be objects of $\mathcal{E}^\otimes$, corresponding to finite sequences of objects $(X_1, \ldots, X_m)$ and $(Y_1, \ldots, Y_{m'})$ of objects of $\mathcal{E}$. Then $\text{Map}_{\mathcal{E}^\otimes}(C,D)$ can be identified with the space

$$
\prod_{\alpha : (m) \to (n)} \prod_{1 \leq i \leq m'} \text{Map}_{\mathcal{E}}(\otimes_{\alpha(i) = j} X_i, Y_j),
$$

and is therefore also $(n-1)$-truncated. Consequently, $\mathcal{E}^\otimes$ is equivalent to an $n$-category. Proposition 5.1.1.4 implies that the forgetful functor $\mathcal{E}_k^\otimes \to \text{N}(\text{Fin}_*)$ induces an equivalence of the underlying homotopy $n$-categories, and therefore induces an equivalence $\theta : \text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{E}^\otimes) \to \text{Fun}_{\mathcal{E}}(\mathcal{E}_k^\otimes, \mathcal{E}_{k+1}^\otimes)$. The desired result now follows from the observation that a map $A \in \text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{E}^\otimes)$ is a commutative algebra object of $\mathcal{E}$ if and only if $\theta(A)$ is an $\mathcal{E}_k$-algebra object of $\mathcal{E}$. \hfill \Box

We now turn to the proof of Theorem 5.1.1.1. We first formulate a general coherence criterion for $\infty$-operads that are obtained as the operadic nerves of simplicial colored operads (Proposition 5.1.1.11). We will then use our analysis of configuration spaces to show that this criterion applies in the case of the $\infty$-operad $\mathcal{E}_k^\otimes$.

**Notation 5.1.1.8.** Let $\mathcal{O}$ be a simplicial operad (that is, a simplicial colored operad having a single distinguished object), and let $\mathcal{O}^\otimes$ be the simplicial category described in Notation 2.1.1.22: the objects of $\mathcal{O}^\otimes$ are objects $\langle n \rangle \in \text{Fin}_*$, and the morphisms spaces $\mathcal{O}^\otimes$ are given by the formula

$$
\text{Map}_{\mathcal{O}^\otimes}(\langle m \rangle, \langle n \rangle) = \prod_{\alpha : (m) \to (n)} \prod_{1 \leq i \leq n} \text{Mul}_{\mathcal{O}}(\alpha^{-1}(i), \{i\})
$$
where α ranges over all maps \( (m) \to (n) \) in \( \mathcal{F}_{\mathcal{I}_a} \). We will say that a morphism in \( \mathcal{O}^\otimes \) is active if its image in \( \mathcal{F}_{\mathcal{I}_a} \) is active, and we let \( \text{Map}^\text{act}_{\mathcal{O}^\otimes}((m), (n)) \) denote the summand of \( \text{Map}_{\mathcal{O}^\otimes}((m), (n)) \) spanned by the active morphisms.

We will say that \( \mathcal{O} \) is unital if \( \text{Mul}_1(\emptyset, \{0\}) \) is isomorphic to \( \Delta^0 \); in this case, every semi-inert morphism \( \alpha : (m) \to (n) \) in \( \mathcal{F}_{\mathcal{I}_a} \) can be lifted uniquely to a morphism \( \bar{\alpha} \) in \( \mathcal{O}^\otimes \). In particular, the canonical inclusion \( i : (m) \to (m + 1) \) admits a unique lift \( \bar{i} : (m) \to (m + 1) \) in \( \mathcal{O}^\otimes \). Composition with \( \bar{i} \) induces a map of simplicial sets
\[
\theta : \text{Map}^\text{act}_{\mathcal{O}^\otimes}((m + 1), (n)) \to \text{Map}^\text{act}_{\mathcal{O}^\otimes}((m), (n)).
\]
For every active morphism \( f : (m) \to (n) \) in \( \mathcal{O}^\otimes \), we will denote the simplicial set \( \theta^{-1}\{f\} \) by \( \text{Ext}_\Delta(f) \); we will refer to \( \text{Ext}_\Delta(f) \) as the space of strict extensions of \( f \).

**Construction 5.1.1.9.** Let \( \mathcal{O} \) be a fibrant simplicial operad, and let \( N^\otimes(\mathcal{O}) \) be the underlying \( \infty \) operad (Definition 2.1.1.23). Suppose we are given a sequence of active morphisms
\[
\langle m_0 \rangle \xrightarrow{f_1} \langle m_1 \rangle \xrightarrow{f_2} \ldots \xrightarrow{f_n} \langle m_n \rangle
\]
in the simplicial category \( \mathcal{O}^\otimes \). This sequence determines an \( n \) simplex \( \sigma \) of \( N^\otimes(\mathcal{O}) \). Let \( S \subseteq [n] \) be a proper nonempty subset having maximal element \( j - 1 \). We define a map of simplicial sets \( \theta : \text{Ext}_\Delta(f_j) \to \text{Ext}(\sigma, S) \) as follows: for every \( k \) simplex \( \tau : \Delta^k \to \text{Ext}_\Delta(f_j) \), \( \theta(\tau) \) is a \( k \) simplex of \( \text{Ext}(\sigma, S) \) corresponding to a map of simplicial categories \( \psi : \mathcal{C}[\Delta^k \times \Delta^{k+1}] \to \mathcal{O}^\otimes \), which may be described as follows:

(i) On objects, the functor \( \psi \) is given by the formula
\[
\psi(n', k') = \begin{cases} 
(m_{n'}) & \text{if } k' = 0 \text{ or } n' \not\in S \\
(m_{n'} + 1) & \text{otherwise}.
\end{cases}
\]

(ii) Fix a pair of vertices \( (n', k'), (n'', k'') \in \Delta^k \times \Delta^{k+1} \). Then \( \psi \) induces a map of simplicial sets \( \phi : \text{Map}_{\mathcal{C}[\Delta^k \times \Delta^{k+1}]}((n', k'), (n'', k'')) \to \text{Map}_{\mathcal{O}^\otimes}(\psi(n', k'), \psi(n'', k'')) \). The left hand side can be identified with the nerve of the partially ordered set \( P \) of chains
\[
(n', k') = (n_0, k_0) \leq (n_1, k_1) \leq \ldots \leq (n_p, k_p) = (n'', k'')
\]
in \( [n] \times [k + 1] \). If \( \psi(n', k') = \langle m_{n'} \rangle \) or \( \psi(n'', k'') = \langle m_{n''} + 1 \rangle \), then \( \phi \) is given by the constant map determined by \( f_{n'} \circ \cdots \circ f_{n''} \). Otherwise, \( \phi \) is given by composing the morphisms \( f_j \circ \cdots \circ f_{n''} \) and \( f_{n'} \circ \cdots \circ f_{n'' + 1} \) with the map
\[
N(P) \xrightarrow{\phi_0} \Delta^k \xrightarrow{\theta} \text{Ext}_\Delta(f_j) \to \text{Map}_{\mathcal{O}^\otimes}(\langle m_{j - 1} + 1 \rangle, \langle m_j \rangle),
\]
where \( \phi_0 \) is induced by the map of partially ordered sets \( P \to [k] \) which carries a chain \( (n', k') = (n_0, k_0) \leq (n_1, k_1) \leq \ldots \leq (n_p, k_p) = (n'', k'') \) to the supremum of the set \( \{k_i - 1 : n_i \in S\} \subseteq [k] \).

**Remark 5.1.1.10.** In the situation of Construction 5.1.1.9, the simplicial set \( \text{Ext}(\sigma, S) \) can be identified with the homotopy fiber of the map
\[
\beta : \text{Map}^\text{act}_{\mathcal{O}^\otimes}(\langle m_{j - 1} + 1 \rangle, \langle m_j \rangle) \to \text{Map}^\text{act}_{\mathcal{O}^\otimes}(\langle m_{j - 1} \rangle, \langle m_j \rangle),
\]
while \( \text{Ext}_\Delta(f_j) \) can be identified with the actual fiber of \( \beta \). The map \( \theta \) of Construction 5.1.1.9 can be identified with the canonical map from the actual fiber to the homotopy fiber.

**Proposition 5.1.1.11.** Let \( \mathcal{O} \) be a fibrant simplicial operad, and assume that every morphism in the underlying simplicial category \( \mathcal{O} = \mathcal{O}^\otimes(1) \) admits a homotopy inverse. Suppose that, for every pair active morphisms \( f_0 : \langle m \rangle \to \langle n \rangle \) and \( g_0 : \langle n \rangle \to \langle 1 \rangle \) in \( \mathcal{O}^\otimes \), there exist morphisms \( f : \langle m \rangle \to \langle n \rangle \), \( h : \langle n \rangle \to \langle n \rangle \), and \( g : \langle n \rangle \to \langle 1 \rangle \) satisfying the following conditions:
(i) The map $f$ is homotopic to $f_0$, the map $g$ is homotopic to $g_0$, and the map $h$ is homotopic to $\text{id}_{(n)}$.

(ii) Each of the sequences

$$\text{Ext}_\Delta(h) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle n+1 \rangle, \langle n \rangle) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle n \rangle, \langle n \rangle)$$

$$\text{Ext}_\Delta(g \circ h) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle n+1 \rangle, \langle 1 \rangle) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle 1 \rangle, \langle 1 \rangle)$$

$$\text{Ext}_\Delta(h \circ f) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle m+1 \rangle, \langle n \rangle) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle m \rangle, \langle n \rangle)$$

$$\text{Ext}_\Delta(g \circ h \circ f) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle m+1 \rangle, \langle 1 \rangle) \rightarrow \text{Map}_{O^\otimes}^{\text{act}}(\langle m \rangle, \langle 1 \rangle)$$

is a homotopy fiber sequence.

(iii) The diagram

$$\begin{array}{ccc}
\text{Ext}_\Delta(h) & \longrightarrow & \text{Ext}_\Delta(g \circ h) \\
\downarrow & & \downarrow \\
\text{Ext}_\Delta(h \circ f) & \longrightarrow & \text{Ext}_\Delta(g \circ h \circ f)
\end{array}$$

is a homotopy pushout square of simplicial sets.

Then the $\infty$-operad $N^\otimes(O)$ is coherent.

Proof. It is clear that $N^\otimes(O)$ satisfies conditions (1) and (2) of Definition 3.3.1.9. We will show that condition (3) is also satisfied. Suppose we are given a degenerate 3-simplex $\sigma :$

$$\begin{array}{c}
\langle n \rangle \\
\downarrow \quad \downarrow f_0 \\
\langle m \rangle \\
\downarrow \quad \downarrow f_0 \\
\langle n \rangle
\end{array}$$

$$\begin{array}{ccc}
\sigma \\
\downarrow \quad \downarrow g_0 \\
\langle 1 \rangle
\end{array}$$

in $N(O)^\otimes$, where $f$ and $g$ are active. We wish to show that the diagram

$$\begin{array}{ccc}
\text{Ext}(\sigma, \{0, 1\}) & \longrightarrow & \text{Ext}(\sigma|\Delta^{(0,1,3)}, \{0, 1\}) \\
\downarrow & & \downarrow \\
\text{Ext}(\sigma|\Delta^{(0,2,3)}, \{0\}) & \longrightarrow & \text{Ext}(\sigma|\Delta^{(0,3)}, \{0\})
\end{array}$$

is a homotopy pushout square of Kan complexes. In proving this, we are free to replace $\sigma$ by any equivalent diagram $\sigma' : \Delta^3 \rightarrow N^\otimes(O)$. We may therefore assume that $\sigma'$ is determined by a triple of morphisms $f : \langle m \rangle \rightarrow \langle n \rangle$, $h : \langle n \rangle \rightarrow \langle n \rangle$, and $g : \langle n \rangle \rightarrow \langle 1 \rangle$ satisfying conditions (ii) and (iii) above. Using Remark 5.1.1.10, we see that Construction 5.1.1.9 determines a weak homotopy equivalence between the diagrams

$$\begin{array}{ccc}
\text{Ext}_\Delta(h) & \longrightarrow & \text{Ext}_\Delta(g \circ h) \\
\downarrow & & \downarrow \\
\text{Ext}_\Delta(h \circ f) & \longrightarrow & \text{Ext}_\Delta(g \circ h \circ f)
\end{array}$$

$$\begin{array}{ccc}
\text{Ext}(\sigma, \{0, 1\}) & \longrightarrow & \text{Ext}(\sigma|\Delta^{(0,1,3)}, \{0, 1\}) \\
\downarrow & & \downarrow \\
\text{Ext}(\sigma|\Delta^{(0,2,3)}, \{0\}) & \longrightarrow & \text{Ext}(\sigma|\Delta^{(0,3)}, \{0\})
\end{array}$$

Since the diagram on the left is a homotopy pushout square by virtue of (iii), the diagram on the right is also a homotopy pushout square. \qed
5.1. DEFINITIONS AND BASIC PROPERTIES

Proof of Theorem 5.1.1.1. Let $O = \text{Sing}^t \mathbb{E}_k$ denote the simplicial operad associated to the topological operad $t \mathbb{E}_k$. We will say that a rectilinear embedding $f \in \text{Rect}(\square^k \times \langle n \rangle^o, \square^k)$ is generic if $f$ can be extended to an embedding $\overline{f} : \overline{\square^k} \times \langle n \rangle^o \to \square^k$, where $\overline{\square^k} = [-1, 1]^k$ is a closed cube of dimension $k$. We will say that an active morphism $f : \langle n \rangle \to \langle m \rangle$ in $O^\otimes$ is generic if it corresponds to a sequence of $m$ rectilinear embeddings which are generic.

We observe the following:

(a) If $f$ is generic, then the difference $\square^k - f(\overline{\square^k} \times \langle n \rangle^o)$ is homotopy equivalent to $\square^k - f(\{0\} \times \langle n \rangle^o)$. It follows that the sequence $\text{Ext}_\Delta(f) \to \text{Map}_{\mathcal{O}^\otimes}(\langle n+1 \rangle, \{1\}) \to \text{Map}_{\mathcal{O}^\otimes}(\langle n \rangle, \{1\})$ is homotopy equivalent to the fiber sequence of configuration spaces (see Lemma 5.1.1.3)

$$\square^k - f(\{0\} \times \langle n \rangle^o) \to \text{Conf}(\langle n+1 \rangle^o, \square^k) \to \text{Conf}(\langle n \rangle^o, \square^k),$$

hence also a homotopy fiber sequence. More generally, if $f : \langle n \rangle \to \langle m \rangle$ is generic, then

$$\text{Ext}_\Delta(f) \to \text{Map}_{\mathcal{O}^\otimes}^{\text{rect}}(\langle n+1 \rangle, \langle m \rangle) \to \text{Map}_{\mathcal{O}^\otimes}^{\text{rect}}(\langle n \rangle, \langle m \rangle),$$

is a fiber sequence.

(b) Every rectilinear embedding $f_0 \in \text{Rect}(\square^k \times \langle n \rangle^o, \square^k)$ is homotopic to a generic rectilinear embedding $f$ (for example, we can take $f$ to be the composition of $f_0$ with the “contracting” map $\square^k \times \langle n \rangle^o \simeq (\frac{1}{2}, \frac{1}{2})^k \times \langle n \rangle^o \hookrightarrow \square^k \times \langle n \rangle^o$). Similarly, every active morphism in $O^\otimes$ is homotopic to a generic morphism.

(c) The collection of generic morphisms in $O^\otimes$ is stable under composition.

To prove that $\mathbb{E}_k^\otimes$ is coherent, it will suffice to show that the simplicial operad $O$ satisfies the criteria of Proposition 5.1.1.11. It is clear that every map in $O$ admits a homotopy inverse (in fact, every rectilinear embedding from $\square^k$ to itself is homotopic to the identity). In view of (a), (b), and (c) above, it will suffice to show that the diagram

$$\begin{array}{ccc}
\text{Ext}_\Delta(h) & \longrightarrow & \text{Ext}_\Delta(g \circ h) \\
\downarrow & & \downarrow \\
\text{Ext}_\Delta(h \circ f) & \longrightarrow & \text{Ext}_\Delta(g \circ h \circ f)
\end{array}$$

is a homotopy pushout square for every triple of active morphisms

$$\langle m \rangle \overset{f}{\longrightarrow} \langle n \rangle \overset{h}{\longrightarrow} \langle n \rangle \overset{g}{\longrightarrow} \langle 1 \rangle$$
in $O^\otimes$, provided that each of the underlying rectilinear embeddings is generic.

Let $U_0 \subseteq U_1 \subseteq U_2$ be the images of $g \circ h \circ f$, $g \circ h$, and $g$, respectively. Let $\overline{U}_i$ denote the closure of $U_i$. We now set

$$V = \square^k - \overline{U}_1 \quad W = U_2 - \overline{U}_0.$$

Note that $V \cup W = \square^k - \overline{U}_0$ and $V \cap W = U_2 - \overline{U}_1$. The argument of Lemma 5.1.1.3 shows that evaluation at the origin of $\square^k$ determines weak homotopy equivalences

$$\text{Ext}_\Delta(h) \to \text{Sing}(V \cap W) \quad \text{Ext}_\Delta(g \circ h) \to \text{Sing}(V)$$

$$\text{Ext}_\Delta(h \circ f) \to \text{Sing}(W) \quad \text{Ext}_\Delta(g \circ h \circ f) \to \text{Sing}(W \cup V).$$

It will therefore suffice to show that the diagram

$$\begin{array}{ccc}
\text{Sing}(V \cap W) & \longrightarrow & \text{Sing}(V) \\
\downarrow & & \downarrow \\
\text{Sing}(W) & \longrightarrow & \text{Sing}(W \cup V)
\end{array}$$

is a homotopy pushout square of Kan complexes, which follows from Theorem A.3.1.
5.1.2 The Additivity Theorem

If \( K \) is a pointed topological space, then the \( k \)-fold loop space \( \Omega^k(K) \) carries an action of the (topological) little cubes operad \( \mathcal{E}_k \). Passing to singular complexes, we deduce that if \( X \in \mathcal{S}_* \), then the \( k \)-fold loop space \( \Omega^k(X) \) can be promoted to an \( E_k \)-algebra object of the \( \infty \)-category \( \mathcal{S} \) of spaces. The work of May provides a converse to this observation: if \( Z \) is a grouplike \( E_k \)-algebra object of \( \mathcal{S} \) (see Definition 5.2.6.6), then \( Z \) is equivalent to \( \Omega^k(Y) \) for some pointed space \( Y \in \mathcal{S}_* \) (see Theorem 5.2.6.15 for a precise statement). The delooping process \( Z \mapsto Y \) is compatible with products in \( Z \). Consequently, if \( Z \) is equipped with a second action of the \( \infty \)-operad \( E_k^\otimes \), which is suitable compatible with the \( E_k \)-action on \( Z \), then we should expect that the space \( Y \) again carries an action of \( E_k^\otimes \), and is therefore itself homotopy equivalent to \( \Omega^k(X) \) for some pointed space \( X \in \mathcal{S}_* \). Then \( Z \simeq \Omega^{k+k'}(X) \) carries an action of the \( \infty \)-operad \( E_{k+k'}^\otimes \). Our goal in this section is to show that this phenomenon is quite general, and applies to algebra objects of an arbitrary symmetric monoidal \( \infty \)-category \( \mathcal{C}^\otimes \): namely, giving an \( E_{k+k'} \)-algebra object of \( \mathcal{C} \) is equivalent to giving an object \( A \in \mathcal{C} \) which is equipped with commuting actions of the \( \infty \)-operads \( E_k^\otimes \) and \( E_{k'}^\otimes \). More precisely, we have a canonical equivalence \( \text{Alg}_{E_{k+k'}}(\mathcal{C}) \simeq \text{Alg}_{E_k}(\mathcal{C}) \otimes \text{Alg}_{E_{k'}}(\mathcal{C}) \) (Theorem 5.1.2.2). Equivalently, we can identify \( E_{k+k'}^\otimes \) with the tensor product of the \( \infty \)-operads \( E_k^\otimes \) and \( E_{k'}^\otimes \) (see Definition 2.2.5.3). We first describe the bifunctor \( E_k^\otimes \times E_{k'}^\otimes \to E_{k+k'}^\otimes \) which gives rise to this identification.

**Construction 5.1.2.1.** Choose nonnegative integers \( k, k' \). We define a topological functor \( \rho : t E_k^\otimes \times t E_{k'}^\otimes \to t E_{k+k'}^\otimes \) as follows:

1. The diagram of functors

\[
\begin{array}{ccc}
t E_k^\otimes \times t E_{k'}^\otimes & \xrightarrow{\rho} & t E_{k+k'}^\otimes \\
\downarrow \quad \downarrow & & \downarrow \\
N(\text{Fin}_n) \times N(\text{Fin}_{n'}) & \xrightarrow{\wedge} & N(\text{Fin}_{n+n'})
\end{array}
\]

commutes, where \( \wedge \) denotes the smash product functor on pointed finite sets (Notation 2.2.5.1). In particular, the functor \( \times \) is given on objects by the formula \( \langle m \rangle \times \langle n \rangle = \langle mn \rangle \).

2. Suppose we are given a pair of morphisms \( \overline{\alpha} : (m) \to (n) \) in \( t E_k^\otimes \) and \( \overline{\beta} : (m') \to (n') \) in \( t E_{k'}^\otimes \). Write \( \overline{\alpha} = (\alpha, \{f_j : \square^k \times \alpha^{-1}(j), \square^k\}_{j \in (n)^e}) \) and \( \overline{\beta} = (\beta, (f'_j : \square^{k'} \times \beta^{-1}(j), \square^{k'})_{j' \in (n')^e}) \). We then define \( \rho(\overline{\alpha}, \overline{\beta}) : (mm') \to (nn') \) to be given by the pair

\[
(\alpha \wedge \beta, \{f_j \times f'_j : \square^{k+k'} \times \alpha^{-1}(j) \times \beta^{-1}(j'), \square^{k+k'}\}_{j \in (n)^e, j' \in (n')^e}).
\]

Passing to homotopy coherent nerves, we obtain a bifunctor of \( \infty \)-operads (see Definition 2.2.5.3) \( E_k^\otimes \times E_{k'}^\otimes \to E_{k+k'}^\otimes \).

A version of the following fundamental result was proven by Dunn (see [41]):

**Theorem 5.1.2.2** (Dunn Additivity Theorem). Let \( k, k' \geq 0 \) be nonnegative integers. Then the bifunctor \( E_k^\otimes \times E_{k'}^\otimes \to E_{k+k'}^\otimes \) of Construction 5.1.2.1 exhibits the \( \infty \)-operad \( E_{k+k'}^\otimes \) as a tensor product of the \( \infty \)-operads \( E_k^\otimes \) and \( E_{k'}^\otimes \) (see Definition 2.2.5.3).

**Example 5.1.2.3** (Baez-Dolan Stabilization Hypothesis). Theorem 5.1.2.2 implies that supplying an \( E_k \)-monoidal structure on an \( \infty \)-category \( \mathcal{C} \) is equivalent to supplying \( k \) compatible monoidal structures on \( \mathcal{C} \). Fix an integer \( n \geq 1 \), and let \( \text{Cat}_{\leq n} \) denote the full subcategory of \( \text{Cat}_{\infty} \) spanned by those \( \infty \)-categories which are equivalent to \( n \)-categories. For \( \mathcal{C}, \mathcal{D} \in \text{Cat}_{\leq n} \), the mapping space \( \text{Map}_{\text{Cat}_{\infty}}(\mathcal{C}, \mathcal{D}) \) is the underlying Kan complex of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \), which is equivalent to an \( n \)-category (Corollary T.2.3.4.8). It follows that \( \text{Cat}_{\leq n} \) is equivalent to an \( (n+1) \)-category. Let us regard \( \text{Cat}_{\leq n} \) as endowed with the Cartesian monoidal structure. Corollary 5.1.1.7 implies that \( \text{CAlg}(\text{Cat}_{\leq n}) \simeq \text{Alg}_{E_k}(\text{Cat}_{\leq n}^\otimes) \) for \( k \geq n+2 \). It follows that if \( \mathcal{C} \) is an \( n \)-category,
then supplying an $E_k$-monoidal structure on $\mathcal{C}$ is equivalent to supplying a symmetric monoidal structure on $\mathcal{C}$ (when $k \geq n + 2$). This can be regarded as a version of the “stabilization hypothesis” proposed in [6] (the formulation above applies to $n$-categories where all $m$-morphisms are invertible for $m > 1$, but the same argument can be applied more generally.)

**Example 5.1.2.4 (Braided Monoidal Categories).** Let $\mathcal{C}$ be an ordinary category. According to Example 5.1.2.3, supplying an $E_k$-monoidal structure on $N(\mathcal{C})$ is equivalent to supplying a symmetric monoidal structure on $\mathcal{C}$ if $k \geq 3$. If $k = 1$, then supplying an $E_k$-monoidal structure on $N(\mathcal{C})$ is equivalent to supplying a monoidal structure on $\mathcal{C}$ (combine Example 2.4.2.4 and Proposition 2.4.2.5) Let us therefore focus our attention on the case $k = 2$. Giving an $E_2$-monoidal structure on $N(\mathcal{C})$ is equivalent to exhibiting $N(\mathcal{C})$ as an $E_2$-algebra object of $\mathcal{C}_{\infty}$. Theorem 5.1.2.2 provides an equivalence $\text{Alg}_{E_2}(\mathcal{C}_{\infty}) \simeq \text{Alg}_{E_1}(\mathcal{C}_{\infty})$. Combining this with Example 2.4.2.4 and Proposition 2.4.2.5, we can view $N(\mathcal{C})$ as an (associative) monoid object in the $\infty$-category $\text{Mon}(\mathcal{C}_{\infty})$ of monoidal $\infty$-categories. This structure allows us to view $\mathcal{C}$ as a monoidal category with respect to some tensor product $\otimes$, together with a second multiplication given by a monoidal functor

$$\boxtimes : (\mathcal{C}, \otimes) \times (\mathcal{C}, \otimes) \to (\mathcal{C}, \otimes).$$

This second multiplication also has a unit, which is a functor from the one-object category $[0]$ into $\mathcal{C}$. Since this functor is required to be monoidal, it carries the unique object of $[0]$ to the unit object $1 \in \mathcal{C}$, up to canonical isomorphism. It follows that $1$ can be regarded as a unit with respect to both tensor product operations $\otimes$ and $\boxtimes$.

We can now exploit the classical Eckmann-Hilton argument to show that the tensor product functors $\otimes, \boxtimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ are isomorphic. Namely, our assumption that $\boxtimes$ is a monoidal functor gives a chain of isomorphisms

$$X \boxtimes Y \simeq (X \otimes 1) \boxtimes (1 \otimes Y) \quad (5.1)$$

$$\simeq (X \otimes 1) \otimes (1 \otimes Y) \quad (5.2)$$

$$\simeq X \otimes Y \quad (5.3)$$

depending naturally on $X$ and $Y$. Consequently, $\boxtimes$ is determined by $\otimes$ as a functor from $\mathcal{C} \times \mathcal{C}$ into $\mathcal{C}$. However, it gives rise to additional data when viewed as a *monoidal* functor: a monoidal structure on the tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ supplies a canonical isomorphism

$$(W \otimes X) \otimes (Y \otimes Z) \simeq (W \otimes Y) \otimes (X \otimes Z).$$

Taking $W$ and $Z$ to be the unit object, we get a canonical isomorphism $\sigma_{X,Y} : X \otimes Y \to Y \otimes X$. Conversely, if we are given a collection of isomorphisms $\sigma_{X,Y} : X \otimes Y \to Y \otimes X$, we can try to endow $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ with the structure of a monoidal functor by supplying the isomorphisms

$$(W \otimes X) \otimes (Y \otimes Z) \simeq W \otimes (X \otimes Y) \otimes Z \overset{\sigma_{X,Y}}{\simeq} W \otimes (Y \otimes X) \otimes Z \simeq (W \otimes Y) \otimes (X \otimes Z)$$

together with the evident isomorphism $1 \otimes 1 \simeq 1$. One can show that construction supplies $\otimes$ with the structure of a monoidal functor if and only if the following conditions are satisfied:

1. For every triple of objects $X, Y, Z \in \mathcal{C}$, the isomorphism $\sigma_{X,Y,\otimes Z}$ is given by the composition

   $$X \otimes (Y \otimes Z) \simeq (X \otimes Y) \otimes Z \overset{\sigma_{X,Y}}{\simeq} (Y \otimes X) \otimes Z \simeq Y \otimes (X \otimes Z) \overset{\sigma_{X,Z}}{\simeq} Y \otimes (Z \otimes X) \simeq (Y \otimes Z) \otimes X.$$

2. For every triple of objects $X, Y, Z \in \mathcal{C}$, the isomorphism $\sigma_{X,\otimes Y,Z}$ is given by the composition

   $$(X \otimes Y) \otimes Z \simeq X \otimes (Y \otimes Z) \overset{\sigma_{X,\otimes Z}}{\simeq} X \otimes (Z \otimes Y) \simeq (X \otimes Z) \otimes Y \overset{\sigma_{X,Y}}{\simeq} (Z \otimes X) \otimes Y \simeq Z \otimes (X \otimes Y).$$

(Equivalently, the inverse maps $\sigma_{X,Y}^{-1} : Y \otimes X \simeq X \otimes Y$ satisfy condition (1).)
A natural isomorphism $\sigma_{X,Y} : X \otimes Y \cong Y \otimes X$ is called a braiding on the monoidal category $(\mathcal{C}, \otimes)$ if it satisfies conditions (1) and (2). A braided monoidal category is a monoidal category equipped with a braiding. We can summarize our discussion as follows: if $\mathcal{C}$ is an ordinary category, then endowing $\mathcal{C}$ with the structure of a braided monoidal category is equivalent to endowing the nerve $N(\mathcal{C})$ with the structure of an $\mathbb{E}_2$-monoidal $\infty$-category.

**Remark 5.1.2.5.** It follows from Example 5.1.2.4 that if $\mathcal{C}$ is a braided monoidal category containing a sequence of objects $X_1, \ldots, X_n$, then the tensor product $X_1 \otimes \cdots \otimes X_n$ is the fiber of a local system of objects of $\mathcal{C}$ over the space $\text{Rect}(\square^2 \times \{1, \ldots, n\}, \square^2)$. In other words, the tensor product $X_1 \otimes \cdots \otimes X_n$ is endowed with an action of the fundamental group $\pi_1 \text{Conf}\{\{1, \ldots, n\}, \mathbb{R}^2\}$ of configurations of $n$ distinct points in the plane $\mathbb{R}^2$ (see Lemma 5.1.1.3). The group $\pi_1 \text{Conf}\{\{1, \ldots, n\}, \mathbb{R}^2\}$ is the Artin pure braid group on $n$ strands. The action of $\pi_1 \text{Conf}\{\{1, \ldots, n\}, \mathbb{R}^2\}$ on $X_1 \otimes \cdots \otimes X_n$ can be constructed by purely combinatorial means, by matching the standard generators of the Artin braid group with the isomorphisms $\sigma_{X_i,X_j}$.

**Corollary 5.1.2.6.** Let $\mathcal{K}$ be some collection of simplicial sets which includes $N(\Delta)^{op}$. Suppose that $\mathcal{C}$ is a symmetric monoidal $\infty$-category which admits colimits indexed by the simplicial sets belonging to $\mathcal{K}$ and for which the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves such colimits separately in each variable. Then for $k \geq 1$, the construction $A \mapsto \text{RMod}_A(\mathcal{C})$ determines a fully faithful functor

$$\text{Alg}_{\mathbb{E}_k}(\mathcal{C}) \to \text{Alg}_{\mathbb{E}_{k-1}}(\text{LMod}_C(\text{Cat}^{\infty}_e(\mathcal{K}))).$$

**Proof.** Combine Corollary 4.8.5.20 and Theorem 5.1.2.2. \qed

**Remark 5.1.2.7.** Corollary 5.1.2.6 furnishes a convenient way of understanding the notion of an $\mathbb{E}_k$-algebra: giving an $\mathbb{E}_k$-algebra object $A \in \text{Alg}_{\mathbb{E}_k}(\mathcal{C})$ is equivalent to giving the underlying associative algebra object $A_0 \in \text{Alg}(\mathcal{C})$, together with an $\mathbb{E}_{k-1}$-structure on the $\infty$-category $\text{RMod}_{A_0}(\mathcal{C})$ of right $A_0$-modules (with unit object given by the module $A_0$ itself).

**Variant 5.1.2.8.** Corollary 5.1.2.6 remains valid (with essentially the same proof) if we assume only that $\mathcal{C}$ is an $\mathbb{E}_k$-monoidal $\infty$-category; in this case, the $\infty$-category $\text{LMod}_C(\text{Cat}^{\infty}_e(\mathcal{K}))$ inherits an $\mathbb{E}_{k-1}$-monoidal structure (see Remark 5.1.2.7).

Let $k, k' \geq 0$ be integers and let $\mathcal{C}$ be an $\mathbb{E}_{k+k'}$-monoidal $\infty$-category. Using the bifunctor of $\infty$-operads $\mathbb{E}_k^\otimes \times \mathbb{E}_{k'}^\otimes \to \mathbb{E}_{k+k'}^\otimes$, we see that $\text{Alg}_{\mathbb{E}_{k+k'}}(\mathcal{C})$ inherits the structure of an $\mathbb{E}_{k'}$-monoidal $\infty$-category. The tensor product on $\text{Alg}_{\mathbb{E}_{k+k'}}(\mathcal{C})$ does not preserve small colimits in general, but it does in the following special case:

**Proposition 5.1.2.9.** Let $k, k' \geq 0$ be integers and let $\mathcal{C}$ be an $\mathbb{E}_{k+k'}$-monoidal $\infty$-category. Let $\kappa$ be an uncountable regular cardinal. Assume that $\mathcal{C}$ admits colimits indexed by $\kappa$-small weakly contractible simplicial sets and that (if $k+k' > 0$) the tensor product on $\mathcal{C}$ preserves colimits indexed by $\kappa$-small weakly contractible simplicial sets separately in each variable. Then:

1. The $\infty$-category $\text{Alg}_{\mathbb{E}_{k+k'}}(\mathcal{C})$ admits colimits indexed by $\kappa$-small weakly contractible simplicial sets.
2. If $k > 0$, then the tensor product

$$\otimes : \text{Alg}_{\mathbb{E}_{k+k'}}(\mathcal{C}) \times \text{Alg}_{\mathbb{E}_{k+k'}}(\mathcal{C}) \to \text{Alg}_{\mathbb{E}_{k+k'}}(\mathcal{C})$$

preserves colimits indexed by $\kappa$-small weakly contractible simplicial sets separately in each variable.

**Proof.** We will assume that $k' > 0$ (the case $k' = 0$ is an immediate consequence of Proposition T.4.4.2.9). We proceed by induction on $k'$. Using Theorem 5.1.2.2, we can reduce to the case $k' = 1$. In this case, assertion (1) follows immediately from Corollary 4.7.4.19. To prove (2), we may assume without loss of
generality that \( k = 1 \) and that \( \mathcal{C} \) is small. Using the constructions described in \S 4.8.1, we can choose a fully faithful \( \mathbb{E}_2 \)-monoidal functor \( f : \mathcal{C} \to \mathcal{C} \) which preserves colimits indexed by \( \kappa \)-small weakly contractible simplicial sets, having the property that \( \mathcal{C} \) is presentable and the tensor product on \( \mathcal{C} \) preserves small colimits separately in each variable. Using Remark 4.7.4.21, we can replace \( \mathcal{C} \) by \( \mathcal{C} \) and thereby reduce to the case where \( \mathcal{C} \) itself is presentable and the tensor product on \( \mathcal{C} \) preserves small colimits separately in each variable. In this case, the construction

\[
A \mapsto \text{RMod}_A(\mathcal{C})
\]
determines a fully faithful embedding \( \theta : \text{Alg}_{\mathbb{E}_2}(\mathcal{C}) \to \text{LMod}_C(\mathcal{P} \mathcal{L}) \) which preserves colimits indexed by \( \kappa \)-small weakly contractible simplicial sets (Corollary 4.8.5.13). Moreover, the functor \( \theta \) is monoidal (see Theorem 4.8.5.16). It will therefore suffice to show that the tensor product on \( \text{LMod}_C(\mathcal{P} \mathcal{L}) \) preserves small colimits separately in each variable. This tensor product factors as a composition

\[
\text{LMod}_C(\mathcal{P} \mathcal{L}) \times \text{LMod}_C(\mathcal{P} \mathcal{L}) \cong \text{LMod}_C \otimes (\mathcal{P} \mathcal{L}) \xrightarrow{F} \text{LMod}_C(\mathcal{P} \mathcal{L}),
\]
where \( F \) is left adjoint to the forgetful functor \( \text{LMod}_C(\mathcal{P} \mathcal{L}) \to \text{LMod}_C \otimes (\mathcal{P} \mathcal{L}) \). We conclude by observing that \( \otimes \) fits into a commutative diagram

\[
\begin{array}{ccc}
\text{LMod}_C(\mathcal{P} \mathcal{L}) \times \text{LMod}_C(\mathcal{P} \mathcal{L}) & \xrightarrow{\otimes} & \text{LMod}_C \otimes (\mathcal{P} \mathcal{L}) \\
\downarrow & & \downarrow \\
\mathcal{P} \mathcal{L} \times \mathcal{P} \mathcal{L} & \xrightarrow{\otimes} & \mathcal{P} \mathcal{L}
\end{array}
\]
where the vertical maps are conservative and preserve small colimits (Corollary 4.2.3.5).

The proof of Theorem 5.1.2.2 will occupy our attention for the remainder of this section. We will need a few auxiliary constructions.

**Construction 5.1.2.10.** Fix integers \( k, k' \geq 0 \). We define a topological category \( W \) as follows:

(a) The objects of \( W \) are finite sequences \( (\langle m_1 \rangle, \ldots, \langle m_b \rangle) \) of objects of \( \text{Fin}_{\ast} \).

(b) Given a pair of objects of \( W = (\langle m_1 \rangle, \ldots, \langle m_b \rangle), W' = (\langle m'_1 \rangle, \ldots, \langle m'_{b'} \rangle) \) of \( W \), the mapping space \( \text{Map}_W(W, W') \) is given by

\[
\prod_{\beta : (b) \to (b')} \text{Map}_{\mathbb{E}_k}(\langle b \rangle, \langle b' \rangle) \times \prod_{\beta(i) = j} \text{Map}_{\mathbb{E}_{k'}}(\langle m_i \rangle, \langle m'_i \rangle).
\]

Here the coproduct is taken over all maps of pointed finite sets \( \beta : \langle b \rangle \to \langle b' \rangle \), and \( \text{Map}_{\mathbb{E}_k}(\langle b \rangle, \langle b' \rangle) \) denotes the inverse image of \( \beta \) under the map \( \text{Map}_{\mathbb{E}_k}(\langle b \rangle, \langle b' \rangle) \to \text{Hom}_{\mathbb{E}_k}(\langle b \rangle, \langle b' \rangle) \).

We observe that there is a canonical isomorphism of \( N(W) \) with the wreath product \( \mathbb{E}_k \wr \mathbb{E}_{k'} \), defined in \S 2.4.4.

There are evident topological functors

\[
\mathcal{T}_k \mathbb{E}_k^\otimes \times \mathcal{T}_k \mathbb{E}_k^\otimes \to W \to \mathcal{T}_k \mathbb{E}_{k+k'}^\otimes,
\]
given on objects by the formulas

\[
(\langle b \rangle, \langle m \rangle) \mapsto (\langle m \rangle, \langle m \rangle, \ldots, \langle m \rangle) \quad (\langle m_1 \rangle, \ldots, \langle m_b \rangle) \mapsto \langle m_1 + \cdots + m_b \rangle,
\]
respectively. Passing to the homotopy coherent nerve, we obtain functors

\[
\mathbb{E}_k^\otimes \times \mathbb{E}_{k'}^\otimes \xrightarrow{\theta'} \mathbb{E}_k^\otimes \wr \mathbb{E}_{k'}^\otimes \cong N(W) \xrightarrow{\theta} \mathbb{E}_{k+k'}^\otimes.
\]
Here \( \theta' \) is the functor described in Remark 2.4.4.2. We will reduce the proof of Theorem 5.1.2.2 to the following:
Proposition 5.1.2.11. Let \( k \geq 0 \) be a nonnegative integer. Then the map \( \theta : E^\otimes_1 \otimes E^\otimes_k \to E^\otimes_{k+1} \) is a weak approximation to the \( \infty \)-operad \( E^\otimes_{k+1} \).

Let us assume Proposition 5.1.2.11 for the moment.

Corollary 5.1.2.12. Let \( k \geq 0 \) be a nonnegative integer. Then the map \( \theta : E^\otimes_1 \otimes E^\otimes_k \to E^\otimes_{k+1} \) described above induces a weak equivalence of \( \infty \)-operads \( (E^\otimes_1 \otimes E^\otimes_k, M) \to E^\otimes_{k+1} \). Here \( M \) denotes the collection of all inert morphisms in \( E^\otimes_1 \otimes E^\otimes_k \) (see Construction 2.4.4.1).

Proof. Let \( \theta_0 \) denote the composition of \( \theta \) with the forgetful functor \( E^\otimes_{k+1} \). We observe that for every object \( X \in E^\otimes_1 \otimes E^\otimes_k \) and every inert morphism \( \alpha : \theta_0(X) \to \langle n \rangle \) in \( \mathcal{N}(\mathcal{F}_{\text{Fin}}) \), there exists a \( \theta_0 \)-coCartesian morphism \( \bar{\sigma} : X \to Y \) lying over \( \alpha \): if \( X = (\langle m_1 \rangle, \ldots, \langle m_b \rangle) \) then we can take \( \bar{\sigma} \) to be the map

\[
(\langle m_1 \rangle, \ldots, \langle m_b \rangle) \to (\langle m'_1 \rangle, \ldots, \langle m'_b \rangle)
\]
determined by a collection of inert morphisms \( \beta_i : (m_i) \to (m'_i) \) with \( \beta_i^{-1}(\langle n \rangle)^\\circ = \alpha^{-1}(\langle n \rangle)^\\circ \cap (m_i)^\\circ \).

Note that the \( \infty \)-category \( \mathcal{E} = (E^\otimes_1 \otimes E^\otimes_k) \times_{\mathcal{N}(\mathcal{F}_{\text{Fin}})} \{1\} \) has a final object \( \langle 1 \rangle \), so that \( \theta \) induces a weak homotopy equivalence \( \mathcal{E} \to E^\otimes_{k+1} \). By the two-out-of-three property, it will suffice to show that a functor \( \phi : E \to E' \) in \( \mathcal{E} \) belongs to \( \mathcal{X} \) if and only if \( F \) carries every inert morphism of \( E^\otimes_1 \otimes E^\otimes_k \) to an inert morphism of \( \mathcal{C}^\otimes \).

Suppose first that \( F \) carries inert morphisms to inert morphisms. Since \( M_0 \) consists of inert morphisms in \( E^\otimes_1 \otimes E^\otimes_k \), it will suffice to show that \( F \) carries every morphism in \( E \to E' \) in \( \mathcal{E} \) to an equivalence in \( \mathcal{C} \). We have a commutative diagram

\[
\begin{array}{ccc}
E & \xrightarrow{\phi} & E' \\
\downarrow \scriptstyle{\langle 1 \rangle} & & \downarrow \scriptstyle{\phi'} \\
\{1\} & & \{1\}
\end{array}
\]

in \( E^\otimes_1 \otimes E^\otimes_k \). By the two-out-of-three property, it will suffice to show that \( F(\phi) \) and \( F(\phi') \) are equivalences in \( \mathcal{C} \), which follows from our assumption since \( \phi \) and \( \phi' \) are inert.

Conversely, suppose that \( F \in \mathcal{X} \); we wish to show that for every inert morphism \( \alpha : X \to X' \) in \( E^\otimes_1 \otimes E^\otimes_k \), the image \( F(\alpha) \) is an inert morphism in \( \mathcal{C}^\otimes \). Arguing as in Remark 2.1.2.9, we can reduce to the case where \( X' \in \mathcal{C} \). Then \( \alpha \) can be written as a composition \( \alpha' \circ \alpha'' \), where \( \alpha'' \in M_0 \) and \( \alpha' \) is a morphism in \( \mathcal{E} \). Our assumption that \( F \in \mathcal{X} \) guarantees that \( F(\alpha') \) is an equivalence and that \( F(\alpha'') \) is inert, so that \( F(\alpha) \) is inert as desired. \( \square \)

Proof of Theorem 5.1.2.2. We proceed by induction on \( k \). If \( k = 0 \), the desired result follows from Proposition 2.3.1.4, since the \( \infty \)-operad \( E^\otimes_k \) is unital. If \( k = 1 \), we consider the factorization

\[
E^\otimes_1 \otimes E^\otimes_k \to (E^\otimes_1 \otimes E^\otimes_k, M) \to E^\otimes_{1+k}
\]

and apply Corollary 5.1.2.12 together with Theorem 2.4.4.3. If \( k > 1 \), we have a commutative diagram

\[
\begin{array}{ccc}
E^\otimes_1 \otimes E^\otimes_{k-1} \otimes E^\otimes_k & \xrightarrow{\otimes} & E^\otimes_k \otimes E^\otimes_{k'} \\
\downarrow \scriptstyle{\otimes} & & \downarrow \scriptstyle{\otimes} \\
E^\otimes_{k+k'} & \rightarrow & E^\otimes_{k+k'}
\end{array}
\]
The inductive hypothesis guarantees that the horizontal maps and the left vertical map are weak equivalences of ∞-preoperads, so that the right vertical map is a weak equivalence as well.

To prove Proposition 5.1.2.11, we first observe that the forgetful functor \( \theta_0 : E_k^* \rightarrow N(\text{Fin}_*) \) satisfies condition \((*)\) of Proposition 2.3.3.11: that is, inert morphisms in \( N(\text{Fin}_*) \) can be lifted to \( \theta_0 \)-coCartesian morphisms in \( E_1 \). For every integer \( n \geq 0 \), we let \( \text{Tup}_n \subseteq N(\text{Fin}_*)/(n) \) be the subcategory whose objects are active maps \( \langle m \rangle \rightarrow \langle n \rangle \) and whose morphisms are equivalences. Fix an object \( X \in E_k \), write \( X = \langle \langle n_1 \rangle, \langle n_2 \rangle, \ldots, \langle n_b \rangle \rangle \), and let \( n = n_1 + \cdots + n_b \). According to Proposition 2.3.3.14, it will suffice to show that the map

\[
(E_1 \times [n])_X \times N(\text{Fin}_*)/(n) \xrightarrow{\text{Tup}_n} (E_1)^{n+1}/(n) \times N(\text{Fin}_*)/(n) \xrightarrow{\text{Tup}_n}
\]

is a weak homotopy equivalence. We define subcategories

\[ (E_1 \times [n])_X \subseteq (E_1)^0_X \subseteq (E_1)^1_X \]

as follows:

- The objects of \( (E_1 \times [n])_X \) are morphisms \( \alpha : \langle \langle m_1 \rangle, \langle m_2 \rangle, \ldots, \langle m_a \rangle \rangle \rightarrow \langle \langle n_1 \rangle, \ldots, \langle n_b \rangle \rangle \) such that the underlying maps \( a \rightarrow b \) and \( m_1 + \cdots + m_a \rightarrow n_1 + \cdots + n_b \) are active morphisms in \( \text{Fin}_* \). Such an object belongs to \( (E_1 \times [n])_X \) if and only if each of the integers \( m_i \) is positive.

- The morphisms in \( (E_1 \times [n])_X \) are given by commutative diagrams

\[
\begin{array}{ccc}
\langle m_1 \rangle, \ldots, \langle m_a \rangle & \xrightarrow{\beta} & \langle m_1', \ldots, m_{a'} \rangle \\
\alpha & & \alpha' \\
\langle n_1 \rangle, \ldots, \langle n_b \rangle & & \\
\end{array}
\]

where \( \alpha \) and \( \alpha' \) belong to \( (E_1 \times [n]) \) and \( \beta \) induces an active map \( \langle a \rangle \rightarrow \langle a' \rangle \) in \( \text{Fin}_* \) and a bijection \( m_1 + \cdots + m_a \rightarrow m_1' + \cdots + m_{a'} \). Such a morphism belongs to \( (E_1 \times [n])_X \) if and only if \( \alpha \) and \( \alpha' \) are objects of \( (E_1 \times [n])_X \).

It is not difficult to see that the inclusions

\[
(E_1 \times [n])_X \subseteq (E_1)^0_X \subseteq (E_1)^1_X
\]

both admit right adjoints, and are therefore weak homotopy equivalences. By the two-out-of-three property, we conclude that the inclusion

\[
(E_1 \times [n])_X \rightarrow (E_1)^0_X \times N(\text{Fin}_*)/(n) \xrightarrow{\text{Tup}_n}
\]

is a weak homotopy equivalence. It will therefore suffice to show that the map

\[
\phi_X : (E_1 \times [n])_X \rightarrow (E_1)^{n+1}/(n) \times N(\text{Fin}_*)/(n) \xrightarrow{\text{Tup}_n}
\]

is a weak homotopy equivalence. We note that \( \phi_X \) is equivalent to a product of maps \( \{ \phi_{\langle \langle n_i \rangle \rangle} \}_{1 \leq i \leq b} \), which allows us to reduce to the case \( b = 1 \). In other words, we can reformulate Proposition 5.1.2.11 as follows:

**Proposition 5.1.2.13.** For each \( n \geq 0 \), the functor \( \theta : E_1 \rightarrow E_k \) induces a weak homotopy equivalence of simplicial sets

\[
\phi : (E_1 \times [n])_X \rightarrow (E_1)^{n+1}/(n) \times N(\text{Fin}_*)/(n) \xrightarrow{\text{Tup}_n}
\]
The remainder of this section is devoted to the proof of Proposition 5.1.2.13.

**Notation 5.1.2.14.** For every topological category \( \mathcal{C} \), we let \( \text{Sing}(\mathcal{C}) \) denote the underlying simplicial category: that is, \( \text{Sing}(\mathcal{C}) \) is the simplicial category having the same objects as \( \mathcal{C} \), with morphism spaces given by

\[
\text{Map}_{\text{Sing}(\mathcal{C})}(X,Y) = \text{Sing}\, \text{Map}_{\mathcal{C}}(X,Y).
\]

If \( F : \mathcal{C} \to \text{Top} \) is a topological functor, we let \( \text{Sing}(F) : \text{Sing}(\mathcal{C}) \to \text{Set}_\Delta \) denote the associated simplicial functor, given by \( \text{Sing}(F)(C) = \text{Sing}(F(C)) \). For every integer \( p \) and every pair of objects \( X, Y \in \mathcal{E}_p \), we let \( \text{Map}^\text{act}_{\mathcal{E}_p}(X,Y) \) denote the summand of the topological space \( \text{Map}^\text{act}_{\mathcal{E}_p}(X,Y) \) spanned by those morphisms whose image in \( \text{Fin}_n \) is active.

Let \( \mathcal{W} \) be the topological category of Construction 5.1.2.10 (so that \( \mathcal{N}(\mathcal{W}) \simeq E_1^{\mathbb{C}} \times E_0^{\mathbb{C}} \)). We let \( \mathcal{W}_0 \) denote the topological subcategory of \( \mathcal{W} \) whose morphisms are maps \( (m_1, \ldots , m_b) \to (m_1', \ldots , m_b') \) which induce an active map \( \langle b \rangle \to \langle b' \rangle \) in \( \text{Fin}_n \), and a bijection \( m_1 + \cdots + m_b \to m_1' + \cdots + m_b' \) in \( \text{Fin}_n \). We define a topological functor \( T : \mathcal{W}_0^{\text{op}} \to \text{Top} \) as follows: for every object \( W = (m_1, \ldots , m_b) \in \mathcal{W}_0 \), we let \( T(W) \) be the summand of \( \text{Map}_{\mathcal{W}}(W, (\langle n \rangle)) \) corresponding to those maps \( (m_1, \ldots , m_b) \to (\langle n \rangle) \) which induce active morphisms \( \langle b \rangle \to (1) \) and \( (m_1 + \cdots + m_b) \to (\langle n \rangle) \) in \( \text{Fin}_n \). We define a counit map. Unwinding the definitions, we obtain a canonical isomorphism of simplicial sets \( (\mathbb{E}_0^1)_{\mathcal{W}_0}^{\text{act}}(\langle n \rangle) \simeq \text{Un}_n \text{Sing}(T) \), where \( \text{Un}_n \) denotes the unstraightening functor of §T.2.2.1.

Let \( \mathcal{E} \) denote the topological subcategory of \( \mathbb{E}_0^1 \) spanned by those morphisms which induce equivalences in \( \mathcal{N}(\text{Fin}_n) \). We define a functor \( U : \mathcal{E}^{\text{op}} \to \text{Top} \) by the formula \( U(E) = \text{Map}^\text{act}_{\mathcal{E}_0^{\mathbb{C}}}(X, \langle n \rangle) \). Let \( U' : \mathcal{C}[\mathcal{N}(\mathcal{E})] \to \text{Sing}(\mathcal{E}) \) be the counit map. Unwinding the definitions, we have a canonical isomorphism of simplicial sets \( (\mathbb{E}_0^1)_{\mathcal{W}_0}^{\text{act}}(\langle n \rangle) \simeq \text{Un}_n \text{Sing}(U) \).

The topological functor \( \xi : \mathcal{W} \to \mathbb{E}_0^1 \) introduced above restricts to a topological functor \( \xi_0 : \mathcal{W}_0 \to \mathcal{E} \). We note that the map \( \phi \) appearing in Proposition 5.1.2.12 can be identified with the map \( \text{Un}_n \text{Sing}(T) \to \text{Un}_n \text{Sing}(U) \) induced by a natural transformation of topological functors \( T \to U \circ \xi_0 \) (which is also determined by \( \xi \)). We will prove that \( \phi \) is a weak homotopy equivalence by assembling \( T \) and \( U \) from simpler constituents. We define a partially ordered set \( P \) as follows:

\( (a) \) The objects of \( P \) are pairs \( (I, \sim) \), where \( I \subseteq (-1, 1) \) is a finite union of open intervals and \( \sim \) is an equivalence relation on the set \( \pi_0 I \). For every point \( x \in I \) we let \( [x] \) denote the corresponding connected component of \( I \). We assume that \( \sim \) is convex in the following sense: if \( x < y < z \) in \( I \) and \( [x] \sim [z] \), then \( [x] \sim [y] \sim [z] \).

\( (b) \) We have \( (I, \sim) \leq (I', \sim') \) if and only if \( I \subseteq I' \) and, for every pair of elements \( x, y \in I \) such that \( [x] \sim' [y] \), we have \( [x] \sim [y] \).

For every element \( (I, \sim) \in P \), we define subfunctors

\[
T_{I, \sim} \subseteq T \quad U_{I, \sim} \subseteq U
\]
as follows:

- Let \( W = (\langle m_1 \rangle, \ldots , \langle m_b \rangle) \) be an object of \( \mathcal{W}_0 \), so that \( T(W) \) is the topological space

\[
\text{Map}^\text{act}_{\mathcal{E}_0^{\mathbb{C}}}(\langle b \rangle, \langle 1 \rangle) \times \coprod_{1 \leq a \leq b} \text{Map}^\text{act}_{\mathcal{E}_0^{\mathbb{C}}}(\langle m_a \rangle, \langle n \rangle)).
\]

We can identify a point of \( T(W) \) with a sequence \( (f, g_1, \ldots , g_b) \), where \( f : \langle b \rangle \to \square^1 \) and \( g_a : \langle m_a \rangle \times \square^k \to \langle n \rangle \times \square^k \) are rectilinear embeddings. We let \( T_{I, \sim}(W) \) be the subset of \( T(W) \) consisting of those sequences which satisfy the following pair of conditions:

\( - \) The image of \( f \) is contained in \( I \). It follows that \( f \) induces a map \( \lambda : \langle b \rangle \to \pi_0 I \).
5.1. DEFINITIONS AND BASIC PROPERTIES

- If \( a, a' \in \langle b \rangle \) satisfy \( \lambda(a) \sim \lambda(a') \), then either \( a = a' \) or the maps \( g_a \) and \( g_{a'} \) have disjoint images.

- Let \( E = \langle m \rangle \) be an object of \( \mathcal{E} \), so that \( U(E) \) is the topological space \( \text{Map}_\Delta^{\text{act}}(\langle m \rangle, \langle n \rangle) = \text{Rect}(\langle m \rangle^\circ \times \square^{k+1}, \langle n \rangle^\circ \times \square^{k+1}) \). Let us identify \( \langle n \rangle^\circ \times \square^{k+1} \) with the product \( \langle n \rangle^\circ \times \square^k \times (-1, 1) \), so that we have projection maps

\[
\langle n \rangle^\circ \times \square^k \xrightarrow{p_0} \langle n \rangle^\circ \times \square^{k+1} \xrightarrow{p_1} (-1, 1).
\]

We let \( U_{I, \sim}(E) \) denote the subspace of \( U(E) \) consisting of those rectilinear embeddings \( f : \langle m \rangle^\circ \times \square^{k+1} \rightarrow \langle n \rangle^\circ \times \square^{k+1} \) satisfying the following conditions:

- The image of \( p_1 \circ f \) is contained in \( I \subseteq (-1, 1) \). Consequently, \( f \) induces a map \( \lambda : \langle n \rangle^\circ \rightarrow \pi_0 I \).

- If \( i, j \in \langle n \rangle \) satisfy \( \lambda(i) \sim \lambda(j) \), then either \( i = j \) or the sets \( \{i\} \times \square^{k+1} \) and \( \{j\} \times \square^{k+1} \) have disjoint images in \( \langle m \rangle^\circ \times \square^k \) (under the map \( p_0 \circ f \)).

It is easy to see that the functors \( T_{I, \sim} : \mathcal{W}_0^{\text{op}} \rightarrow \text{Top} \) and \( U_{I, \sim} : \mathcal{E}^{\text{op}} \rightarrow \text{Top} \) depend functorially on the pair \( (I, \sim) \in P \). Moreover, the natural transformation \( T \rightarrow U \circ \xi_0 \) determined by \( \xi \) restricts to natural transformations \( T_{I, \sim} \rightarrow U_{I, \sim} \circ \xi_0 \). According to Theorem T.2.2.1.2, the unstraightening functor \( U_n \) is a right Quillen equivalence from \( (\text{Set}_\Delta)^{\text{Sing}(\mathcal{W}_0)^{\text{op}}} \) (endowed with the projective model structure) to \( (\text{Set}_\Delta)^{\text{Sing}(\mathcal{W}_0)^{\text{op}}} \) (endowed with the contravariant model structure); it follows that \( U_n \) carries homotopy colimit diagrams between fibrant objects of \( (\text{Set}_\Delta)^{\text{Sing}(\mathcal{W}_0)^{\text{op}}} \) to homotopy colimit diagrams in \( \text{Set}_\Delta \) (with respect to the usual model structure). Similarly, \( U_{\sim n} \) carries homotopy colimit diagrams between fibrant objects of \( (\text{Set}_\Delta)^{\text{Sing}(\mathcal{E})^{\text{op}}} \) to homotopy colimit diagrams in \( \text{Set}_\Delta \). Consequently, to prove Proposition 5.1.2.13 it will suffice to show the following:

**Proposition 5.1.2.16.** The functor \( \text{Sing}(\mathcal{T}) \) is a homotopy colimit of the diagram of functors \( \{\text{Sing}(T_{I, \sim}) : \text{Sing}(\mathcal{W}_0)^{\text{op}} \rightarrow \text{Set}_\Delta\}_{(I, \sim) \in P} \).

**Proposition 5.1.2.17.** The functor \( \text{Sing}(\mathcal{U}) \) is a homotopy colimit of the diagram of functors \( \{\text{Sing}(U_{I, \sim}) : \mathcal{E}^{\text{op}} \rightarrow \text{Set}_\Delta\}_{(I, \sim) \in P} \).

**Proposition 5.1.2.18.** For every element \( (I, \sim) \in P \), the topological functor \( \xi \) induces a weak homotopy equivalence of simplicial sets \( U_n \text{Sing}(T_{I, \sim}) \rightarrow U_{\sim n} \text{Sing}(U_{I, \sim}) \).

**Proof of Proposition 5.1.2.16.** Fix an object \( W = (\langle m_1 \rangle, \ldots, \langle m_b \rangle) \in \mathcal{W}_0 \); we wish to show that \( \text{Sing}(\mathcal{T}(W)) \) is a homotopy colimit of the diagram \( \{\text{Sing}(T_{I, \sim}(W))\}_{(I, \sim) \in P} \). Let \( T'(W) \) denote the configuration space

\[
\text{Conf}(\langle b \rangle^\circ, (-1, 1)) \times \prod_{1 \leq a \leq b} \text{Conf}(\langle m_a \rangle^\circ, \langle n \rangle^\circ \times \square^k).
\]

We can identify \( T'(W) \) with the set of tuples \( (f, g_1, \ldots, g_b) \), where \( f : \langle b \rangle^\circ \rightarrow (-1, 1) \) and and \( g_a : \langle m_a \rangle^\circ \rightarrow \langle n \rangle^\circ \times \square^k \) are injective maps. Given \( (I, \sim) \in P \), let \( T'_{I, \sim}(W) \) be the open subset of \( T'(W) \) consisting of those tuples \( (f, g_1, \ldots, g_b) \) satisfying the following conditions:

- The image of the map \( f \) is contained in \( I \subseteq (-1, 1) \), so that \( f \) induces a map \( \lambda : \langle b \rangle^\circ \rightarrow \pi_0 I \).

- If \( a, a' \in \langle b \rangle \) satisfy \( \lambda(a) \sim \lambda(a') \), then either \( a = a' \) or the maps \( g_a \) and \( g_{a'} \) have disjoint images.

Evaluation at the origins of \( \square^1 \) and \( \square^k \) determines a map \( \mathcal{T}(W) \rightarrow T'(W) \) which restricts to maps \( T_{I, \sim}(W) \rightarrow T'_{I, \sim}(W) \) for each \( (I, \sim) \in P \). It follows from Lemma 5.1.1.3 that each of these maps is a homotopy equivalence. It will therefore suffice to show that \( \text{Sing}(\mathcal{T}(W)) \) is a homotopy colimit of the diagram of simplicial sets \( \{\text{Sing}(T'_{I, \sim}(W))\}_{(I, \sim) \in P} \). According to Theorem A.3.1, it will suffice to prove the following:

(*) Let \( x = (f, g_1, \ldots, g_b) \) be a point of \( T'(W) \), and let \( P_x = \{(I, \sim) \in P : x \in T'_{I, \sim}(W)\} \). Then the simplicial set \( N(P_x) \) is weakly contractible.
Let $x$ be as in $(\ast)$, and let $P'_x$ denote the subset of $P_x$ consisting of those triples where $f$ induces a surjection $\lambda : (\langle b \rangle)^\circ \to \pi_0 I$. The inclusion $N(P'_x) \hookrightarrow N(P_x)$ admits a right adjoint and is therefore a weak homotopy equivalence. It will therefore suffice to show that $N(P'_x)$ is weakly contractible.

Let $Q$ be the collection of all equivalence relations $\sim$ on the set $\langle b \rangle^\circ$ which have the following properties:

(i) If $f(a) \leq f(a') \leq f(a'')$ and $a \sim a''$, then $a \sim a' \sim a''$.

(ii) If $a \sim a'$ and the image of $g_a$ intersects the image of $g_{a'}$, then $a = a'$.

We regard $Q$ as a partially ordered set with respect to refinement. Pullback of equivalence relations along $\lambda$ determines a forgetful functor $\mu : N(P'_x) \to N(Q)^{op}$. It is easy to see that $\mu$ is a Cartesian fibration. The simplicial set $N(Q)$ is weakly contractible, since $Q$ has a smallest element (given by the equivalence relation where $a \sim a'$ if and only if $a = a'$). We will complete the proof of $(\ast)$ by showing that the fibers of $\mu$ are weakly contractible, so that $\mu$ is left cofinal (Lemma T.4.1.3.2) and therefore a weak homotopy equivalence.

Fix an equivalence relation $\sim \in Q$. Unwinding the definitions, we see that $\mu^{-1}\{\sim\}$ can be identified with the nerve of the partially ordered set $R$ consisting of those subsets $I \subseteq (-1, 1)$ satisfying the following conditions:

(a) The set $I$ is a finite union of open intervals.

(b) The set $I$ contains the image of $f$.

(c) If $f(a)$ and $f(a')$ belong to the same connected component of $I$, then $a \sim a'$.

To see that $N(R)$ is contractible, it suffices to observe that the partially ordered set $R^{op}$ is filtered: this follows from the fact that $R$ is nonempty (it contains $\bigcup_{a \in \langle b \rangle^\circ} (f(a) - \epsilon, f(a) + \epsilon)$ for sufficiently small $\epsilon > 0$) and is closed under pairwise intersections.

**Proof of Proposition 5.1.2.17.** The proof is essentially the same as that of Proposition 5.1.2.16, with some minor modifications. Fix an object $E = (m) \in \mathcal{E}$. We wish to show that $\operatorname{Sing}(E)$ is a homotopy colimit of the diagram $\{\operatorname{Sing} U_{I, \sim}(E)\}_{(I, \sim) \in P}$. Write $(n)^{\circ} \times \Box^{k+1}$ as a product $(n)^{\circ} \times 0 \times (-1, 1)$, and consider the projection maps

$$(n)^{\circ} \times \Box^{k} \xrightarrow{P_0} (n)^{\circ} \times \Box^{k+1} \xrightarrow{P_1} (-1, 1).$$

Let $U'(E) = \operatorname{Conf}((m)^{\circ}, (n)^{\circ} \times \Box^{k+1})$ be the collection of injective maps $f = (f_0, f_1) : (m)^{\circ} \to (n)^{\circ} \times \Box^{k} \times (-1, 1)$. For every pair $(I, \sim) \in P$, we let $U'_{I, \sim}(E)$ denote the open subset of $U'(E)$ consisting of those functions $f = (f_0, f_1)$ which satisfy the following conditions:

- The image of $f_1$ is contained in $I \subseteq (-1, 1)$, so that $f_1$ induces a map $\lambda : (m)^{\circ} \to \pi_0 I$.

- If $i, j \in (m)^{\circ}$ satisfy $\lambda(i) \sim \lambda(j)$, then either $i = j$ or $f_0(i) \neq f_0(j)$.

Evaluation at the origin of $\Box^{k+1}$ determines a map $U(E) \to U'(E)$ which restricts to maps $U_{I, \sim}(E) \to U'_{I, \sim}(E)$ for each $E \in \mathcal{E}$. It follows from Lemma 5.1.1.3 that each of these maps is a homotopy equivalence. It will therefore suffice to show that $\operatorname{Sing}(U'(E))$ is a homotopy colimit of the diagram of simplicial sets $\{\operatorname{Sing} U'_{I, \sim}(E)\}_{(I, \sim) \in P}$. According to Theorem A.3.1, it will suffice to prove the following:

$(\ast)$ Let $f = (f_0, f_1)$ be a point of $U'(E)$, and let $P_x = \{(I, \sim) \in P : x \in U'_{I, \sim}(E)\}$. Then the simplicial set $N(P_x)$ is weakly contractible.

Let $f$ be as in $(\ast)$, and let $P'_x$ denote the subset of $P_x$ consisting of those triples where $f_1$ induces a surjection $\lambda : (m)^{\circ} \to \pi_0 I$. The inclusion $N(P'_x) \hookrightarrow N(P_x)$ admits a right adjoint and is therefore a weak homotopy equivalence. It will therefore suffice to show that $N(P'_x)$ is weakly contractible.

Let $Q$ be the collection of all equivalence relations $\sim$ on the set $(m)^{\circ}$ which have the following properties:

(i) If $f_1(i) \leq f_1(i') \leq f_1(i'')$ and $i \sim i''$, then $i \sim i' \sim i''$. 
(ii) If $i \sim i'$ and $f_0(i) = f_0(i')$, then $i = i'$.

We regard $Q$ as a partially ordered set with respect to refinement. Pullback of equivalence relations along $\lambda$ determines a Cartesian fibration functor $\mu : N(P'_E) \to N(Q)^{op}$. The simplicial set $N(Q)$ is weakly contractible, since $Q$ has a smallest element (given by the equivalence relation where $i \sim j$ if and only if $f_1(i) = f_1(j)$).

We will complete the proof of $(\ast)$ by showing that the fibers of $\mu$ are weakly contractible, so that $\mu$ is left cofinal (Lemma T.4.1.3.2) and therefore a weak homotopy equivalence.

Fix an equivalence relation $\sim \in Q$. Unwinding the definitions, we see that $\mu^{-1}(\sim)$ can be identified with the nerve of the partially ordered set $R$ consisting of those subsets $I \subseteq (-1,1)$ satisfying the following conditions:

(a) The set $I$ is a finite union of open intervals.

(b) The set $I$ contains the image of $f_1$.

(c) If $f_0(i)$ and $f_1(j)$ belong to the same connected component of $I$, then $i \sim j$.

To see that $N(R)$ is contractible, it suffices to observe that the partially ordered set $R^{op}$ is filtered: this follows from the fact that $R$ is nonempty (it contains $\bigcup_{i \in \{n\}}(f_1(i) - \epsilon, f_1(i) + \epsilon)$ for sufficiently small $\epsilon > 0$) and closed under pairwise intersections.

Proof of Proposition 5.1.2.18. We define a functor $T^0_{I,\sim} : W_0^{op} \to \text{Top}$ by the formula $T^0_{I,\sim}(\langle m_1, \ldots, m_b \rangle) = \text{Rect}((b)^{\circ} \times (-1,1), I)$. There is an evident natural transformation $T^0_{I,\sim} \to T^0_{I,\sim}$ which induces a (projective) fibration of simplicial functors $\text{Sing}(T^0_{I,\sim}) \to \text{Sing}(T^0_{I,\sim})$ and therefore a right fibration of simplicial sets $\chi : \text{Un}_n \text{Sing}(T^0_{I,\sim}) \to \text{Un}_n \text{Sing}(T^0_{I,\sim})$. Unwinding the definitions, we can identify an object of $\text{Un}_n \text{Sing}(T^0_{I,\sim})$ with an object $W = (\langle m_1, \ldots, m_b \rangle) \in W_0$ and a rectilinear embedding $f : (b)^{\circ} \times (-1,1) \to I$. Let $X \subseteq \text{Un}_n \text{Sing}(T^0_{I,\sim})$ be the full subcategory of $\text{Un}_n \text{Sing}(T^0_{I,\sim})$ spanned by those pairs $(W,f)$ for which $f$ induces a bijection $(b)^{\circ} \to \pi_0 I$. It is not difficult to see that the inclusion $X \subseteq \text{Un}_n \text{Sing}(T^0_{I,\sim})$ admits a left adjoint and is therefore left cofinal. Since $\chi$ is a right fibration, we deduce that the inclusion

$$X \times_{\text{Un}_n \text{Sing}(T^0_{I,\sim})} \text{Un}_n \text{Sing}(T^0_{I,\sim}) \to \text{Un}_n \text{Sing}(T^0_{I,\sim})$$

is also left cofinal (Lemma T.4.1.3.2), and therefore a weak homotopy equivalence.

Define a functor $U^0_{I,\sim} : \mathcal{E} \to \text{Top}$ by the formula $U^0_{I,\sim}(m) = \text{Hom}_{\text{Set}}((m)^{\circ}, \pi_0 I)$. We have a commutative diagram

$$\begin{array}{ccc}
X \times_{\text{Un}_n \text{Sing}(T^0_{I,\sim})} \text{Un}_n \text{Sing}(T^0_{I,\sim}) & \xrightarrow{\gamma} & \text{Un}_{n'} \text{Sing}(U^0_{I,\sim}) \\
\downarrow & & \downarrow \\
X & \xrightarrow{F_0} & \text{Un}_{n'} \text{Sing}(U^0_{I,\sim}).
\end{array}$$

We will complete the proof by showing that the upper horizontal map is an equivalence of $\infty$-categories. Unwinding the definitions, we deduce easily that $F_0$ is an equivalence of $\infty$-categories: both the domain and codomain of $F_0$ are equivalent to the Kan complex $\text{Tup}_{\pi_0 I}$. The vertical maps are right fibrations; it will therefore suffice to show that $F$ induces a homotopy equivalence between the fibers of the vertical maps.

This amounts to the following assertion:

$(\ast)$ For every object $W = (\langle m_1, \ldots, m_b \rangle) \in W_0$ having image $E = \langle m_1 + \cdots + m_b \rangle = \langle m \rangle$ in $\mathcal{E}$, if $\eta \in T^0_{I,\sim}(W)$ determines an isomorphism $(b)^{\circ} \simeq \pi_0 I$ having image $\eta' \in U^0_{I,\sim}(E)$, then the induced map

$$\gamma : \text{Sing}(T^0_{I,\sim}(W)) \times_{T^0_{I,\sim}(W)} \{\eta\} \to \text{Sing}(U^0_{I,\sim}(E)) \times_{U^0_{I,\sim}(E)} \{\eta'\}$$

is a homotopy equivalence.
In fact, $\gamma$ is the product of an identity map with the inclusion of a point into the product

$$\prod_{1 \leq i \leq m} \text{Rect}((-1,1), I_i),$$

where $I_i$ denotes the connected component of $I$ which is the image of $i \in \langle m \rangle \circ$ under the map $\eta' : \langle m \rangle \circ \to \pi_0 I$.

The desired result now follows from the fact that each embedding space $\text{Rect}((-1,1), I_i)$ is contractible (Lemma 5.1.1.3).□

### 5.1.3 Tensor Products of $\mathbb{E}_k$-Modules

Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category and let $A \in \text{Alg}_{\mathbb{E}_k}(\mathcal{C})$ be an $\mathbb{E}_k$-algebra object of $\mathcal{C}$. Under some mild assumptions, the $\infty$-category $\text{Mod}_{\mathbb{E}_k}(\mathcal{C})$ of has the structure of an $\mathbb{E}_k$-monoidal $\infty$-category (see Corollary 3.4.4.6). In particular, if $k \geq 1$ then we have a tensor product operation

$$\otimes : \text{Mod}_{\mathbb{E}_k}(\mathcal{C}) \times \text{Mod}_{\mathbb{E}_k}(\mathcal{C}) \to \text{Mod}_{\mathbb{E}_k}(\mathcal{C}).$$

Our goal in this section is to show that this operation is, in some sense, independent of $n$. More precisely, we show that there is a monoidal forgetful functor $\text{Mod}_{\mathbb{E}_k}(\mathcal{C}) \to \text{Mod}_{\mathbb{E}_{1}}(\mathcal{C})$ is monoidal, where $A'$ denotes the image of $A$ in $\text{Alg}(\mathcal{C})$. In other words, there is a forgetful functor from $\text{Mod}_{\mathbb{E}_k}(\mathcal{C})$ to the $\infty$-category $\text{BMod}_{\mathcal{C}}(\mathcal{C})$ of $A$-$A$-bimodule objects of $\mathcal{C}$, and that the tensor product $\otimes$ corresponds (under this forgetful functor) to the relative tensor product $\otimes_A$ of §4.4.2.

**Construction 5.1.3.1.** Let $f : \mathcal{O} \otimes \to \mathcal{O}' \otimes$ be a map of coherent $\infty$-operads. Then $f$ induces a map $F : \mathcal{K}_{\mathcal{O}} \to \mathcal{K}_{\mathcal{O}'}$ (see Notation 3.3.2.1). Suppose we are given a fibration of $\infty$-operads $\mathcal{E} \otimes \to \mathcal{O} \otimes$, and set $\mathcal{E}^\otimes = \mathcal{E} \otimes \times_{\mathcal{O} \otimes} \mathcal{O}' \otimes$. Composition with $F$ determines a map $\text{Mod}^{\mathcal{O}}(\mathcal{E})^\otimes \times_{\mathcal{O} \otimes} \mathcal{O}' \otimes \to \text{Mod}^{\mathcal{O}'}(\mathcal{E}')^\otimes$. This map fits into a commutative diagram

$$
\begin{array}{ccc}
\text{Mod}^{\mathcal{O}}(\mathcal{E})^\otimes \times_{\mathcal{O} \otimes} \mathcal{O}' \otimes & \longrightarrow & \text{Mod}^{\mathcal{O}'}(\mathcal{E}')^\otimes \\
\downarrow & & \downarrow \\
\text{Alg}_{/\mathcal{O}}(\mathcal{E}) & \longrightarrow & \text{Alg}_{/\mathcal{O}'}(\mathcal{E}').
\end{array}
$$

Consequently, for every algebra object $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ having image $A' \in \text{Alg}_{/\mathcal{O}'}(\mathcal{C})$, we obtain a map $\text{Mod}^{\mathcal{O}}(\mathcal{E})^\otimes \times_{\mathcal{O} \otimes} \mathcal{O}' \otimes \to \text{Mod}^{\mathcal{O}'}(\mathcal{E}')^\otimes$.

We can now state our main result:

**Theorem 5.1.3.2.** Let $k \geq 1$ be an integer and let $q : \mathcal{E}^\otimes \to \mathbb{B}_k^\otimes$ be a coCartesian fibration of $\infty$-operads. Assume that $\mathcal{E}$ admits geometric realizations of simplicial objects and that the tensor product functor $\otimes : \mathcal{E} \times \mathcal{E} \to \mathcal{E}$ preserves geometric realizations of simplicial objects. Let $A \in \text{Alg}_{/\mathcal{E}_k}(\mathcal{C})$. Then:

(1) The map $\text{Mod}_{\mathbb{E}_k}(\mathcal{C})^\otimes \to \mathbb{B}_k^\otimes$ is a coCartesian fibration of $\infty$-operads.

(2) Let $A'$ denote the image of $A$ in $\text{Alg}_{/\mathcal{E}_k}(\mathcal{C})$. Then the map

$$F : \text{Mod}_{\mathbb{E}_k}(\mathcal{C})^\otimes \times_{\mathbb{B}_k^\otimes} \mathbb{B}_1^\otimes \to \text{Mod}_{\mathbb{E}_k}(\mathcal{C})$$

of Construction 5.1.3.1 is a monoidal functor.

**Remark 5.1.3.3.** We can regard Theorem 4.5.2.1 as a limiting case of Theorem 5.1.3.2, where we take $k = \infty$. 

---

580 \ CHAPTER 5. LITTLE CUBES AND FACTORIZABLE SHEAVES
The remainder of this section is devoted to the proof of Theorem 5.1.3.2. Like the proof of Theorem 5.1.2.2, it rests on a calculation of the homotopy type of certain configuration spaces.

**Notation 5.1.3.4.** Fix an integer \( n \geq 0 \). We let \( \mathcal{J}_n \) denote the subcategory of \( \mathcal{F}_{\text{inj}}(\mathcal{J}_n) \) whose objects are injective maps \( (m) \rightarrow (m') \) and whose morphisms are commutative diagrams

\[
\begin{array}{ccc}
(m) & \xrightarrow{\alpha} & (m') \\
\downarrow & & \downarrow \\
(a) & & (a')
\end{array}
\]

where \( \alpha \) is a bijection. We define a category \( \mathcal{J}_n \) as follows:

- **The objects of** \( \mathcal{J}_n \) **are sequences** \( (\langle m_1 \rangle, \ldots, \langle m_k \rangle) \), **where** \( (\langle m_1 \rangle, \ldots, \langle m_k \rangle) \) **is an object of** \( \mathcal{N}(\mathcal{F}_{\text{inj}})^{\leq k} \) **and** \( \rho : (a)^\circ \rightarrow (m_1 + \cdots + m_k)^\circ \) **is an injection which induces an injection** \( (a)^\circ \rightarrow (b)^\circ \).

- **A morphism in** \( \mathcal{J}_n \) **from** \( (\langle m_1 \rangle, \ldots, \langle m_k \rangle) \) **to** \( (\langle m'_1 \rangle, \ldots, \langle m'_{k'} \rangle) \) **is a morphism**

\[
(\langle m_1 \rangle, \ldots, \langle m_k \rangle) \rightarrow (\langle m'_1 \rangle, \ldots, \langle m'_{k'} \rangle)
\]

**which induces an active map** \( (b) \rightarrow (b') \) **and a bijection** \( \alpha : (m_1 + \cdots + m_k) \rightarrow (m'_1 + \cdots + m'_{k'}) \) **such that** \( \rho' = \alpha \circ \rho \).

Let \( W \) be the topological category of Construction 5.1.2.10 (so that \( \mathcal{N}(W) \cong \mathcal{E}_k \)). We let \( W_n \) denote the fiber product \( W \times_{\mathcal{K}(\mathcal{N}(\mathcal{F}_{\text{inj}})^{\leq k})} \mathcal{J}_n \). We define a topological functor \( T^a : W^a \rightarrow \mathcal{T} \mathcal{op} \rightarrow \text{Top} \) as follows: for every object \( (W, \rho) \in W_n \), we let \( T(W) \) be the summand of \( \text{Map}_{W}(W, ((1))) \) corresponding to those maps \( W = (\langle m_1 \rangle, \ldots, \langle m_k \rangle) \rightarrow ((1)) \) which induce active morphisms \( (b) \rightarrow (1) \) and \( (m_1 + \cdots + m_k) \rightarrow (1) \) in \( \mathcal{F}_{\text{inj}} \).

Let \( U^n \) denote the space \( \text{Rect}(\langle a \rangle^\circ \times \Box^1, \Box^1) \times \text{Rect}(\Box^{k-1}, \Box^{k-1})^a \). For each \( (W, \rho) \in W_n \), composition with \( \rho \) determines a continuous map \( T^a(W, \rho) \rightarrow U^n \).

Let \( \mathcal{E}_a \) denote the topological category \( \mathcal{E}_k \times_{\mathcal{F}_{\text{inj}}} \mathcal{J}_n \). We will identify objects of \( \mathcal{E}_a \) with pairs \( (\langle m \rangle, \rho) \), where \( (\langle m \rangle) \in \mathcal{E}_k \) and \( \rho : (a) \rightarrow (m) \) is an injective map of finite linearly ordered sets. We define a topological functor \( U^a : \mathcal{E}_a \rightarrow \text{Top} \) by the formula \( U^a((\langle m \rangle), \rho) = \text{Map}_{\mathcal{E}_k}(\langle m \rangle, (1)) \). Let \( U^0_a \) be the topological space \( \text{Map}_{\mathcal{E}_k}(\langle 1 \rangle, (1)) = \text{Rect}(\langle a \rangle^\circ \times \Box^k, \Box^k) \), so that for every object \( (\langle m \rangle, \rho) \in \mathcal{E}_a \) composition with \( \rho \) determines a map of topological spaces \( U^a((\langle m \rangle), \rho) \rightarrow U^0_a \).

**Remark 5.1.3.5.** The functors \( T^a \) and \( U^a \) of Notation 5.1.3.4 are given by the composition

\[
\begin{array}{ccc}
W_a^\text{op} & \xrightarrow{T} & \mathcal{T} \mathcal{op} \\
\xrightarrow{U^a} & & \text{Top},
\end{array}
\]

where \( T \) and \( U^a \) are the functors defined in Notation 5.1.2.14 in the special case \( n = 1 \). If \( a = 0 \), then we can identify \( T^a \) with \( T \) and \( U^a \) with \( U \), and the topological spaces \( T^a_0 \) and \( U^0 \) consist of a single point.

Let \( \nu : \mathcal{C}[\mathcal{N}(W_a)] \rightarrow \text{Sing}(W_a) \) and \( \nu' : \mathcal{C}[\mathcal{N}(\mathcal{E}_a)] \rightarrow \text{Sing}(\mathcal{E}_a) \) be the counit maps. We let \( \ast \) denote the simplicial category consisting of a single object, and regard the simplicial sets \( \text{Sing}(U^a_0) \) and \( \text{Sing}(T^a_0) \) as simplicial functors \( \ast \rightarrow \mathcal{S} \). Let \( \nu'' : \mathcal{C}[\Delta^0] \rightarrow \ast \) be the canonical equivalence. The topological functor \( \xi : W \rightarrow \mathcal{E}_k \) restricts to a topological functor \( \xi_0 : W_a \rightarrow \mathcal{E}_a \), and we have a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\text{Un}_\nu \text{Sing}(T^a_0) & \xrightarrow{\text{Un}_\nu} & \text{Un}_\nu \text{Sing}(T^a_0) \\
\downarrow & & \downarrow \\
\text{Un}_\nu \text{Sing}(U^a) & \xrightarrow{\text{Un}_\nu} & \text{Un}_\nu \text{Sing}(U^a),
\end{array}
\]

where \( \text{Un} \) denotes the unstraightening functor of §T.2.2.1.

We will need the following result:
Proposition 5.1.3.6. For every integer \( a \geq 0 \), the diagram of simplicial sets \( \sigma : \)

\[
\begin{array}{ccc}
\text{Un}_v \text{Sing}(T^a) & \longrightarrow & \text{Un}_v \text{Sing}(T_0^a) \\
\downarrow & & \downarrow \\
\text{Un}_{v'} \text{Sing}(U^a) & \longrightarrow & \text{Un}_{v'} \text{Sing}(U_0^a)
\end{array}
\]

is a homotopy pullback square (with respect to the usual model structure on \( \text{Set}_\Delta \)).

Remark 5.1.3.7. In the situation of Proposition 5.1.3.6, the simplicial sets \( \text{Un}_v \text{Sing}(U^a) \), \( \text{Un}_{v'} \text{Sing}(T_0^a) \), and \( \text{Un}_{v'} \text{Sing}(T_0^a) \) are Kan complexes, but \( \text{Un}_v \text{Sing}(T^a) \) is merely an \( \infty \)-category. Consequently, \( \sigma \) is not a homotopy pullback diagram with respect to the Joyal model structure. Let \( S \) denote the homotopy fiber product \( (\text{Un}_v \text{Sing}(U^a)) \times_{\text{Un}_{v'} \text{Sing}(T_0^a)} (\text{Un}_{v'} \text{Sing}(T_0^a)) \), so that \( \sigma \) determines a functor \( f : \text{Un}_v \text{Sing}(T^a) \to S \). Proposition 5.1.3.6 is equivalent to the assertion that the homotopy fibers of \( f \) (computed with respect to the Joyal model structure) are weakly contractible.

Remark 5.1.3.8. In the special case \( a = 0 \), Proposition 5.1.3.6 follows from Proposition 5.1.2.13.

We will prove Proposition 5.1.3.6 at the end of this section. Let us now see that it implies Theorem 5.1.3.2.

Proof of Theorem 5.1.3.2. Let \( q' : \text{Mod}^E_A(\mathcal{C})^\otimes \to \mathcal{E}_{k}^\otimes \) and \( q'' : \text{Mod}^E_A(\mathcal{C})^\otimes \to \mathcal{E}_1^\otimes \) be the projection maps. Fix an object \( \tilde{M} \in \text{Mod}^E_A(\mathcal{C})^\otimes \) and a morphism \( \gamma : \langle n \rangle \to \langle m \rangle \) in \( \mathcal{E}_{k}^\otimes \). To prove (1), we must show that \( \gamma \) can be lifted to a \( q'\)-coCartesian morphism \( \tilde{\gamma} : \tilde{M} \to N \in \text{Mod}^E_A(\mathcal{C})^\otimes \). We may assume without loss of generality that \( \gamma \) is the image of a morphism \( \gamma_0 : \langle n \rangle \to \langle m \rangle \) in \( \mathcal{E}_1^\otimes \), so that \( \tilde{\gamma} \) determines a map \( T(\tilde{\gamma}) \) in \( \text{Mod}^E_A(\mathcal{C}) \). To prove (2), we must show that \( F(\tilde{\gamma}) \) is \( q''\)-coCartesian.

For \( 1 \leq i \leq m \), let \( n_i \) denote the cardinality of the inverse image of \( \{ i \} \) under the map of pointed finite sets \( \langle n \rangle \to \langle m \rangle \). Factor the map \( \gamma_0 \) as a composition

\[
\langle n \rangle \xrightarrow{\gamma_0'} \langle n' \rangle \xrightarrow{\gamma_0''} \langle m \rangle,
\]

where \( \gamma_0' \) is inert and \( \gamma_0'' \) is active. Replacing \( \gamma_0 \) with \( \gamma_0'' \), we can reduce to the case where \( \gamma_0 \) is active. Then \( \gamma_0 \) is an amalgam of active maps \( \langle n_i \rangle \to \langle 1 \rangle \); we may therefore assume that \( m = 1 \). If \( n = 0 \), the desired result follows from Example 3.4.4.7. If \( n = 1 \), the map \( \gamma_0 \) is an equivalence and there is nothing to prove. If \( n > 2 \), then the map \( \gamma_0 \) factors as a composition

\[
\langle n \rangle \to \langle n - 1 \rangle \to \langle 1 \rangle
\]

each of which has fibers of cardinality \( < n \), and the desired result follows from the inductive hypothesis. We may therefore assume without loss of generality that \( n = 2 \).

Let \( D = \Delta^1 \times_{\mathcal{E}_k} \mathcal{K}_{\mathbb{Z}_k} \) and \( D' = \Delta^1 \times_{\mathcal{E}_1} \mathcal{K}_{\mathbb{Z}_1} \), be as in the statement of Theorem 3.4.4.3. Let \( D' \in \overline{D'} \) correspond to the identity map \( \langle 1 \rangle \to \langle 1 \rangle \) in \( \mathcal{E}_1 \), and let \( D \) be the image of \( D' \) in \( D \). Set \( D = \overline{D} \times_{\Delta^1} \{ 0 \} \) and \( D' = \overline{D'} \times_{\Delta^1} \{ 0 \} \). Let \( D_{\text{act}^1} \) be the full subcategory of \( \overline{D} \times_{\Delta^1} D \) spanned by those diagrams

\[
\begin{array}{ccc}
\langle 2 \rangle & \xrightarrow{\alpha} & X \\
\downarrow \gamma & & \downarrow \beta \\
\langle 1 \rangle & \longrightarrow & \langle 1 \rangle
\end{array}
\]

where \( \beta \) is active (here \( \alpha \) is semi-inert), and let \( D'_{\text{act}^1} \) be defined similarly.
According to Theorem 3.4.4.3, assertion (1) will follow if we can solve the lifting problem depicted in the diagram

\[
\begin{array}{ccc}
\mathcal{D}_{/D}^{\text{act}} & \xrightarrow{f} & \mathcal{C}^\otimes \\
\downarrow & & \downarrow q \\
(\mathcal{D}_{/D}^{\text{act}})^{\circ} & \xrightarrow{f^\circ} & \mathcal{E}_{k}^\otimes
\end{array}
\]

so that \( f \) is an operadic \( q \)-colimit diagram. Moreover, assertion (2) will follow if we show that the composite map \((\mathcal{D}_{/D'}^{\text{act}})^{^\circ} \rightarrow (\mathcal{D}_{/D}^{\text{act}})^{^\circ} \xrightarrow{f^\circ} \mathcal{E}^\otimes\) is also an operadic \( q \)-colimit diagram.

We will prove the following:

(*) The map of \( \infty \)-operads \( E_1 \rightarrow E_k \) induces a left cofinal functor \( \mathcal{D}_{/D'}^{\text{act}} \rightarrow \mathcal{D}_{/D}^{\text{act}} \).

Assuming (*), we are reduced to the problem of solving the lifting problem

\[
\begin{array}{ccc}
\mathcal{D}_{/D'}^{\text{act}} & \xrightarrow{f'} & \mathcal{C}^\otimes \\
\downarrow & & \downarrow q \\
(\mathcal{D}_{/D'}^{\text{act}})^{\circ} & \xrightarrow{f'^\circ} & \mathcal{E}_{k}^\otimes
\end{array}
\]

so that \( f' \) is an operadic \( q \)-colimit diagram. The equivalence \( E_1^\otimes \rightarrow \text{Ass}^\otimes \) of Example 5.1.0.7 induces an equivalence of \( \mathcal{D}_{/D'}^{\text{act}} \) with the full subcategory \( \mathcal{J} \) of \( \text{Ass}^\otimes \langle 2 \rangle / \langle 1 \rangle \) spanned by those factorizations

\[
\begin{array}{ccc}
\langle a \rangle & \xrightarrow{\alpha} & \langle 1 \rangle \\
\downarrow & & \downarrow \\
\langle 2 \rangle & \xrightarrow{\beta} & \langle 1 \rangle
\end{array}
\]

where \( \alpha \) is injective and \( \beta \) is active. The map \( \beta \) determines a linear ordering of \( \langle a \rangle^\circ \). Let \( \mathcal{J}_0 \) be the full subcategory of \( \mathcal{J} \) spanned by those diagrams for which the image of \( \alpha \) contains the smallest and largest elements of \( \langle a \rangle^\circ \). The inclusion \( \mathcal{J}_0 \hookrightarrow \mathcal{J} \) admits a left adjoint, and is therefore left cofinal. It will therefore suffice to show that every lifting problem of the form

\[
\begin{array}{ccc}
\mathcal{J}_0 & \longrightarrow & \mathcal{C}^\otimes \\
\downarrow & & \downarrow q \\
\mathcal{J}_0 & \longrightarrow & \mathcal{E}_{k}^\otimes
\end{array}
\]

admits a solution, where \( g \) is an operadic \( q \)-colimit diagram. This follows from Proposition 3.1.1.20, since there is an equivalence of \( \infty \)-categories \( \mathcal{J}_0 \simeq N(\Delta)^{op} \).

It remains to prove (*). Let \( W \) be as in Construction 5.1.2.10, so that the inclusion \( i : E_1^\otimes \to E_k^\otimes \) factors as a composition

\[
E_1^\otimes \hookrightarrow i' \to N(W) \to E_k^\otimes
\]

(see Construction 5.1.2.10). Let \( \mathcal{D}' \) denote the subcategory of

\[
\text{Fun}(\Delta^1, N(W)) /_{\text{id}_{\langle 1 \rangle}} \times_{\text{Fun}(\Delta^1, N(W)) /_{\langle 1 \rangle}} \{ \{1\}, \{1\} \}
\]

whose objects are diagrams

\[
\begin{array}{ccc}
\{1\} & \xrightarrow{\alpha} & \{m_1, \ldots, m_k\} \\
\downarrow & & \downarrow \\
\{1\} & \xrightarrow{\beta} & \{1\}
\end{array}
\]
where the maps \( (2) \to (b) \) and \( (2) \to (m_1 + \cdots + m_b) \) determined by \( \alpha \) are injective, and the maps \( (b) \to (1) \) and \( (m_i) \to (1) \) determined by \( \beta \) are active. Morphisms in \( \D'' \) are given by diagrams

\[
\begin{array}{ccc}
(1, 1) & \longrightarrow & (\langle m'_1, \ldots, m'_b \rangle) \\
\downarrow & & \downarrow \beta' \\
(1, 1) & \longrightarrow & (\langle m_1, \ldots, m_b \rangle) \\
\downarrow & & \downarrow \\
(1, 1) & \longrightarrow & (1)
\end{array}
\]

where \( \beta' \) induces an active map \( \langle b' \rangle \to \langle b \rangle \). The map \( i' \) induces a functor \( \D^{\text{act}} \to \D'' \). This functor admits a left adjoint and is therefore left cofinal. Consequently, to prove \( (*) \) it will suffice to show that \( i'' \) induces a left cofinal functor \( Q : \D'' \to \D^{\text{act}} \).

Fix an object \( E \in \D^{\text{act}}_D \). According to Theorem T.4.1.3.1, it will suffice to show that \( \infty \)-category \( X = (\D^{\text{act}}_D)^{\otimes 0} \times_{\D^{\text{act}}_D} \D'' \) is weakly contractible. We can identify objects of \( X \) with pairs \( (E, u : E \to Q(E)) \), where \( E \) is an object of \( \D'' \) and \( u \) is a morphism in \( \D^{\text{act}}_D \). Let \( X^0 \) be the full subcategory of \( X \) spanned by those objects for which \( u \) is an equivalence. Using Proposition 5.1.2.11 and Theorem T.4.1.3.1, we deduce that the inclusion \( X^0 \to X \) is right cofinal, and therefore a weak homotopy equivalence. It will therefore suffice to show that \( X^0 \) is weakly contractible. The \( \infty \)-category \( X^0 \) can be identified with a homotopy fiber of the map \( \Un_\varepsilon \text{Sing}(\Top^2) \to S \) appearing in Remark 5.1.3.7, and is therefore weakly contractible by Proposition 5.1.3.6.

We now turn to the proof of Proposition 5.1.3.6. We begin by defining a functor \( \tilde{T}^a : \W_a^{\text{op}} \to \Top \), given on objects by the formula \( \tilde{T}^a(W, \rho) = T^a(W) \times (\Box^k)^a \). Given a morphism \( \alpha : (W, \rho) \to (W', \rho') \) in \( \W_a^{\text{op}} \), we let

\[
\tilde{T}^a(\alpha) : T^a(W) \times (\Box^k)^a \to T^a(W') \times (\Box^k)^a
\]

be given by

\[
(f, \{p_i \in \Box^k\}_{1 \leq i \leq a}) \mapsto (T^a(\alpha)(f), \{\phi_i(p_i) \in \Box^k\}_{1 \leq i \leq a}),
\]

where \( \phi_i : \Box^k \to \Box^k \) denotes the rectilinear embedding determined by restricting \( \alpha \) to the cube indexed by \( \rho(i) \). Define \( \tilde{U}^a : \E_a^{\text{op}} \to \Top \) similarly, so that we have natural transformations of functors

\[
\tilde{T}^a \to T^a \quad \tilde{U}^a \to U
\]

which induce a commutative diagram

\[
\begin{array}{ccc}
\Un_{\varepsilon} \text{Sing}(\tilde{T}^a) & \longrightarrow & \Un_{\varepsilon} \text{Sing}(T^a) \\
\downarrow & & \downarrow \\
\Un_{\varepsilon'} \text{Sing}(\tilde{U}^a) & \longrightarrow & \Un_{\varepsilon'} \text{Sing}(U^a)
\end{array}
\]

\[
\begin{array}{ccc}
\Un_{\varepsilon} \text{Sing}(\tilde{T}_0^a) & \longrightarrow & \Un_{\varepsilon} \text{Sing}(T_0^a) \\
\downarrow & & \downarrow \\
\Un_{\varepsilon'} \text{Sing}(\tilde{U}_0^a) & \longrightarrow & \Un_{\varepsilon'} \text{Sing}(U_0^a)
\end{array}
\]

Since \( (\Box^k)^a \) is contractible, the horizontal maps on the left of the diagram are categorical equivalences (and therefore weak homotopy equivalences). Consequently, to prove Proposition 5.1.3.6, it will suffice to show that the outer rectangle is a homotopy pullback square.

Let \( U_0^a \) denote the open subset of \( \Conf((a)^0, \Box^k) \times U_0^a = \Conf((a)^0, \Box^k) \times \Rect((a)^0 \times \Box^k, \Box^k) \) consisting of those pairs \((p, f)\), where \( p : (a)^0 \to \Box^k \) is an injective map and \( f : (a)^0 \times \Box^k \to \Box^k \) is a rectilinear embedding satisfying \( p(i) \in f(\{i\} \times \Box^k) \) for \( 1 \leq i \leq a \). Let \( T_0^a \) denote the fiber product \( T_0^a \times_{U_0^a} U_0^a \). We
regard $\text{Sing}(T_0^a)$ and $\text{Sing}(U_0^a)$ as simplicial functors $\ast \to \text{Set}_\Delta$, so that we have a commutative diagram

$$
\begin{array}{c}
\text{Un}_v \text{Sing}(\hat{T}^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(\hat{U}^a)
\end{array}
\quad \begin{array}{c}
\text{Un}_v \text{Sing}(T_0^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(U_0^a)
\end{array}
\quad \begin{array}{c}
\text{Un}_v \text{Sing}(\tilde{T}_0^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(U_0^a)
\end{array}
\quad \begin{array}{c}
\text{Un}_v \text{Sing}(\hat{T}_0^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(\hat{U}_0^a)
\end{array}

Here the left horizontal maps are trivial Kan fibrations. We are therefore reduced to showing that the square on the right is a homotopy pullback.

Let $U_0^{\prime\prime}$ denote the configuration space $\text{Conf}(\langle a \rangle^o, \square^k)$ and let $T_0^{\prime\prime}$ denote the open subset of $U_0^{\prime\prime}$ consisting of configurations such that the composite map $\langle a \rangle^o \to \square^1$ is injective. There are canonical projection maps

$$
U_0^{\prime\prime} \to U_0^{\prime\prime} \quad T_0^{\prime\prime} \to T_0^{\prime\prime}
$$

and it follows easily from Lemma 5.1.1.3 that these maps are homotopy equivalences. We regard $\text{Sing}(T_0^{\prime\prime})$ and $\text{Sing}(U_0^{\prime\prime})$ as simplicial functors $\ast \to \text{Set}_\Delta$, so that we have a commutative diagram

$$
\begin{array}{c}
\text{Un}_v \text{Sing}(\hat{T}^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(\hat{U}^a)
\end{array}
\quad \begin{array}{c}
\text{Un}_v \text{Sing}(T_0^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(U_0^a)
\end{array}
\quad \begin{array}{c}
\text{Un}_v \text{Sing}(\tilde{T}_0^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(\tilde{U}_0^a)
\end{array}
\quad \begin{array}{c}
\text{Un}_v \text{Sing}(\hat{T}_0^a) \\
\downarrow \\
\text{Un}_v \text{Sing}(\hat{U}_0^a)
\end{array}

where the left horizontal maps are categorical equivalences. It will therefore suffice to show that the outer rectangle is a homotopy pullback square.

Fix a point $p \in T_0^{\prime\prime}$, which we identify with an injective map $\langle a \rangle^o \to \square^k$. We will show that the homotopy fiber of the map $\phi : \text{Un}_v \text{Sing}(\hat{T}^a) \to \text{Un}_v \text{Sing}(\tilde{T}_0^a)$ over the point $p$ is weakly homotopy equivalent to the homotopy fiber of the map $\phi' : \text{Un}_v \text{Sing}(\hat{U}^a) \to \text{Un}_v \text{Sing}(\tilde{U}_0^a)$ over $p$. For every object $(W, \rho) \in W_a^o$, the map $T^a(W, \rho) \to T_0^{\prime\prime}$ is a Serre fibration; let us denote its fiber over $p$ by $\hat{T}(W, \rho)$. Similarly, for $(E, \rho) \in E_a^o$, the map $U^a(E, \rho) \to U_0^{\prime\prime}$ is a Serre fibration, and we will denote its fiber by $\hat{U}(E, \rho)$. We regard $\hat{T}$ as a topological functor $W_a^o \to \text{Top}$ and $\hat{U}$ as a topological functor $E_a^o \to \text{Top}$. Note that the homotopy fibers of $\phi$ and $\phi'$ can be identified with $\text{Un}_v \text{Sing}(\hat{T})$ and $\text{Un}_v \text{Sing}(\hat{U})$, respectively. Consequently, we can reformulate Proposition 5.1.3.6 as follows:

**Proposition 5.1.3.9.** For every $a \geq 0$ and every point $p \in \text{Conf}(\langle a \rangle^o, \square^1 \times \square^{k-1})$ which determines an injective map $\langle a \rangle^o \to \square^1$, the induced map $\text{Un}_v \text{Sing}(\hat{T}) \to \text{Un}_v \text{Sing}(\hat{U})$ is a weak homotopy equivalence of simplicial sets.

**Remark 5.1.3.10.** In what follows, we let

$$
T : W_0^{op} \to \text{Top} \quad U : E^{op} \to \text{Top}
$$

be as in Notation 5.1.2.14 (where we take the parameter $n$ appearing in Notation 5.1.2.14 to be equal to 1). Unwinding the definitions, we see that for $W = (\langle m_1 \rangle, \ldots, \langle m_k \rangle) \in W$ and $(W, \rho) \in W_a$, we can identify $\hat{T}(W, \rho)$ with the open subset of $T(W)$ consisting of those embeddings $f : \langle m_1 \rangle + \cdots + \langle m_k \rangle \to \square^k$ such that $p(i) \in f(\langle \rho(i) \rangle \times \square^k)$ for $1 \leq i \leq a$. Similarly, if $(\langle m \rangle, \rho) \in E_a$, then $\hat{U}(\langle m \rangle, \rho)$ can be identified with the open subset of $U(\langle m \rangle)$ consisting of those embeddings $f : \langle m \rangle \to \square^k$ such that $p(i) \in f(\langle \rho(i) \rangle \times \square^k)$ for $1 \leq i \leq a$.

We will prove Proposition 5.1.3.9 using the same strategy as our proof of Proposition 5.1.2.13: namely, we will assemble $\hat{T}$ and $\hat{U}$ by forming homotopy colimits of simpler functors, for which the desired conclusion is easier to verify.
we define subfunctors (here we take the parameter \( n \) appearing in Construction 5.1.2.15 to be 1). For every element \((I, \sim) \in P\), we define subfunctors

\[
\hat{T}_{I, \sim} \subseteq \hat{T} \quad \hat{U}_{I, \sim} \subseteq \hat{U}
\]

by the formulas

\[
\hat{T}_{I, \sim}(W, \rho) = \hat{T}(W, \rho) \times_{T(W)} T_{I, \sim}(W) \quad \hat{U}_{I, \sim}(E, \rho) = \hat{U}(E, \rho) \times_{U(E)} U_{I, \sim}(E).
\]

As in the proof of Proposition 5.1.2.13, we are reduced to proving the following trio of assertions:

Proposition 5.1.3.12. The functor \( \text{Sing}(\hat{T}) \) is a homotopy colimit of the diagram of functors \( \{ \text{Sing}(\hat{T}_{I, \sim}) : \text{Sing}(W_{\alpha})^{\text{op}} \rightarrow \text{Set}_{\Delta^1} \}_{(I, \sim) \in P} \).

Proposition 5.1.3.13. The functor \( \text{Sing}(\hat{U}) \) is a homotopy colimit of the diagram of functors \( \{ \text{Sing}(\hat{U}_{I, \sim}) : \text{Sing}(E)^{\text{op}} \rightarrow \text{Set}_{\Delta^1} \}_{(I, \sim) \in P} \).

Proposition 5.1.3.14. For every element \((I, \sim) \in P\), the canonical map \( \text{Un}_v \hat{T}_{I, \sim} \rightarrow \text{Un}_v \hat{U}_{I, \sim} \) is a weak homotopy equivalence.

Proof of Proposition 5.1.3.12. Fix an object \( W = (\langle m_1 \rangle, \ldots, \langle m_b \rangle) \in W_0 \) and an object \((W, \rho) \in W_a\); we wish to show that \( \text{Sing}(\hat{T}(W, \rho)) \) is a homotopy colimit of the diagram \( \{ \text{Sing}(\hat{T}_{I, \sim}(W, \rho)) \}_{(I, \sim) \in P} \). For \( 1 \leq i \leq a \), we let \( \rho_{-}(i) \) denote the image of \( i \) in \( (b)_{\ast}^{\circ} \), and \( \rho_{+}(i) \) the corresponding element of \( (m_{\rho_{-}(i)})_{\ast}^{\circ} \).

Let \( X \) denote the subspace of

\[
\text{Conf}(\langle b \rangle_{\ast}^{\circ}, (-1, 1)) \times \prod_{1 \leq a \leq b} \text{Conf}(\langle m_a \rangle_{\ast}^{\circ}, \Box^k)
\]

consisting of tuples \((f, g_1, \ldots, g_b)\) such that, for \( 1 \leq i \leq a \), we have \( p(i) = (f(\rho_{-}(i)), g_{\rho_{-}(i)}(\rho_{+}(i))) \). For each \((I, \sim) \in P\), we let \( X_{I, \sim} \) denote the open subset of \( X \) consisting of those tuples \((f, g_1, \ldots, g_b)\) satisfying the following conditions:

- The image of the map \( f \) is contained in \( I \subseteq (-1, 1) \), so that \( f \) induces a map \( \lambda : (b)_{\ast}^{\circ} \rightarrow \pi_0 I \).
- If \( a, a' \in \langle b \rangle_{\ast}^{\circ} \) satisfy \( \lambda(a) \sim \lambda(a') \), then either \( a = a' \) or the maps \( g_a \) and \( g_{a'} \) have disjoint images.

Lemma 5.1.3 determines a homotopy equivalence \( \hat{T}(W, \rho) \rightarrow X \) which restricts to a homotopy equivalence \( \hat{T}_{I, \sim}(W, \rho) \rightarrow X_{I, \sim} \) for each \((I, \sim) \in P\). It will therefore suffice to show that \( \text{Sing}(X) \) is the homotopy colimit of the diagram \( \{ \text{Sing} X_{I, \sim} \}_{(I, \sim) \in P} \). According to Theorem A.3.1, it will suffice to prove the following:

\((\ast)\) Let \( x = (f, g_1, \ldots, g_b) \) be a point of \( X \), and let \( P_x = \{ (I, \sim) \in P : x \in X_{I, \sim} \} \). Then the simplicial set \( N(P_x) \) is weakly contractible.

The proof now proceeds exactly as in the proof of Proposition 5.1.2.16. Let \( x \) be as in \((\ast)\), and let \( P'_x \) denote the subset of \( P_x \) consisting of those triples where \( f \) induces a surjection \( \lambda : (b)_{\ast}^{\circ} \rightarrow \pi_0 I \). The inclusion \( N(P'_x) \hookrightarrow N(P_x) \) admits a right adjoint and is therefore a weak homotopy equivalence. It will therefore suffice to show that \( N(P'_x) \) is weakly contractible.

Let \( Q \) be the collection of all equivalence relations \( \sim \) on the set \( \langle b \rangle_{\ast}^{\circ} \) which have the following properties:

(i) If \( f(i) \leq f(i') \leq f(i'') \) and \( i \sim i'' \), then \( i \sim i' \sim i'' \).

(ii) If \( i \sim i' \) and the image of \( g_i \) intersects the image of \( g_{i'} \), then \( i = i' \).
5.1. DEFINITIONS AND BASIC PROPERTIES

We regard $Q$ as a partially ordered set with respect to refinement. Pullback of equivalence relations along $\lambda$ determines a forgetful functor $\mu : N(P'_x) \to N(Q)^{op}$. It is easy to see that $\mu$ is a Cartesian fibration. The simplicial set $N(Q)$ is weakly contractible, since $Q$ has a smallest element (given by the equivalence relation where $i \sim i'$ if and only if $i = i'$). We will complete the proof of $(\ast)$ by showing that the fibers of $\mu$ are weakly contractible, so that $\mu$ is left cofinal (Lemma T.4.1.3.2) and therefore a weak homotopy equivalence.

Fix an equivalence relation $\sim \in Q$. Unwinding the definitions, we see that $\mu^{-1}(\sim)$ can be identified with the nerve of the partially ordered set $R$ consisting of those subsets $I \subseteq (-1, 1)$ satisfying the following conditions:

(a) The set $I$ is a finite union of open intervals.

(b) The set $I$ contains the image of $f$.

(c) If $f(a)$ and $f(a')$ belong to the same connected component of $I$, then $a \sim a'$.

To see that $N(R)$ is contractible, it suffices to observe that the partially ordered set $R^{op}$ is filtered: this follows from the fact that $R$ is nonempty (it contains $\bigcup_{\epsilon > 0} (f(a) - \epsilon, f(a) + \epsilon)$ for sufficiently small $\epsilon > 0$) and is closed under pairwise intersections. \hfill $\square$

**Proof of Proposition 5.1.3.13.** The proof is essentially the same as that of Proposition 5.1.3.12, with some minor modifications. Fix an object $E = \langle m \rangle \in E$ and an lifting $(E, \rho) \in E_{a}$; we wish to show that $\text{Sing} \bar{U}(W, \rho)$ is a homotopy colimit of the diagram $\{\text{Sing} \bar{U}_I(E, \rho)\}_{(I, \sim) \in P}$. Let $X$ denote the subspace of $\text{Conf}(\langle m \rangle^0, \square^k)$ consisting of injective maps $f : \langle m \rangle^0 \to \square^k$ satisfying $f(\rho(i)) = p(i)$ for $1 \leq i \leq a$. We identify such a map $f$ with a pair of maps $(f_0, f_1)$, where $f_0 : \langle m \rangle^0 \to \square^{k-1}$ and $f_1 : \langle m \rangle^0 \to \square^1$. For each $(I, \sim) \in P$, we let $X_{I, \sim}$ denote the open subset of $X$ consisting of those maps $f = (f_0, f_1)$ satisfying the following condition:

- The image of the map $f_1$ is contained in $I$, so that $f_1$ induces a map $\lambda : \langle m \rangle^0 \to \pi_0 I$.

- If $i, j \in \langle m \rangle^0$ satisfy $\lambda(i) \sim \lambda(j)$, then either $i = j$ or $f_0(i) \neq f_0(j)$.

Lemma 5.1.1.3 determines a homotopy equivalence $\bar{U}(E, \rho) \to X$ which restricts to a homotopy equivalence $\bar{T}_{I, \sim}(W, \rho) \to X_{I, \sim}$ for each $(I, \sim) \in P$. It will therefore suffice to show that $\text{Sing}(X)$ is the homotopy colimit of the diagram $\{\text{Sing} X_{I, \sim} \}_{(I, \sim) \in P}$. According to Theorem A.3.1, it will suffice to prove the following:

$(\ast)$ Let $f = (f_0, f_1)$ be a point of $X$, and let $P_x = \{(I, \sim) \in P : f \in X_{I, \sim}\}$. Then the simplicial set $N(P_x)$ is weakly contractible.

Let $f$ be as in $(\ast)$, and let $P'_x$ denote the subset of $P_x$ consisting of those triples where $f_1$ induces a surjection $\lambda : \langle m \rangle^0 \to \pi_0 I$. The inclusion $N(P'_x) \hookrightarrow N(P_x)$ admits a right adjoint and is therefore a weak homotopy equivalence. It will therefore suffice to show that $N(P'_x)$ is weakly contractible.

Let $Q$ be the collection of all equivalence relations $\sim$ on the set $\langle m \rangle^0$ which have the following properties:

(i) If $f_1(i) \leq f_1(i')$ and $i \sim i'$, then $i \sim i' \sim i''$.

(ii) If $i \sim i'$ and $f_0(i) = f_0(i')$, then $i = i'$.

We regard $Q$ as a partially ordered set with respect to refinement. Pullback of equivalence relations along $\lambda$ determines a Cartesian fibration functor $\mu : N(P'_x) \to N(Q)^{op}$. The simplicial set $N(Q)$ is weakly contractible since $Q$ has a smallest element (given by the equivalence relation where $i \sim j$ if and only if $f_1(i) = f_1(j)$). We will complete the proof of $(\ast)$ by showing that the fibers of $\mu$ are weakly contractible so that $\mu$ is left cofinal (Lemma T.4.1.3.2) and therefore a weak homotopy equivalence.

Fix an equivalence relation $\sim \in Q$. Unwinding the definitions, we see that $\mu^{-1}(\sim)$ can be identified with the nerve of the partially ordered set $R$ consisting of those subsets $I \subseteq (-1, 1)$ satisfying the following conditions:

(a) The set $I$ is a finite union of open intervals.
(b) The set $I$ contains the image of $f_1$.

(c) If $f_0(i)$ and $f_1(j)$ belong to the same connected component of $I$, then $i \sim j$.

To see that $N(R)$ is contractible, it suffices to observe that the partially ordered set $R^\op$ is filtered: this follows from the fact that $R$ is nonempty (it contains $\bigcup_{i \in \langle a \rangle^\circ} (f_1(i) - \epsilon, f_1(i) + \epsilon)$ for sufficiently small $\epsilon > 0$) and closed under pairwise intersections.

**Proof of Proposition 5.1.3.14.** Identify $\square^k$ with the product $\square^{k-1} \times \square^1$, and let

$$
\pi_0 : \square^k \to \square^{k-1} \quad \pi_1 : \square^k \to \square^1
$$

be the projection maps. We define a functor $\pi_0 : \hat{T}_{I,\sim}^0 : \mathcal{W}_a^\op \to \text{Top}$ by the formula

$$
\hat{T}_{I,\sim}^0((\langle m_1 \rangle, \ldots, \langle m_b \rangle), \rho) = \{ f \in \text{Rect}(\langle b \rangle^\circ \times \square^1, I) : \pi_1(p(i)) \in f(\langle \rho_-(i) \} \times \square^1) \},
$$

where $\rho_-(a^\circ) \to \langle b \rangle^\circ$ is defined as in the proof of Proposition 5.1.3.12. There is an evident natural transformation $\hat{T}_{I,\sim} \to \hat{T}_{I,\sim}^0$, which induces a (projective) fibration of simplicial functors $\text{Sing}(\hat{T}_{I,\sim}) \to \text{Sing}(\hat{T}_{I,\sim}^0)$ and therefore a right fibration of simplicial sets $\chi : \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}) \to \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0)$. Unwinding the definitions, we can identify an object of $\text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0)$ with an object $W = ((m_1), \ldots, (m_b)) \in \mathcal{W}_a$, an injective map of pointed finite sets $\rho : \langle a \rangle \to (m_1 + \cdots + m_b)$, and a rectilinear embedding $f : \langle b \rangle^\circ \times \square^1 \to I$. Let $X \subseteq \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0)$ be the subcategory of $\text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0)$ spanned by those pairs $(W, \rho, f)$ for which $f$ induces a bijection $\langle b \rangle^\circ \to \pi_0 I$. It is not difficult to see that the inclusion $X \subseteq \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0)$ admits a left adjoint and is therefore left cofinal. Since $\chi$ is a right fibration, we deduce that the inclusion

$$
X \times \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0) \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}) \to \text{Un}_n \text{Sing}(\hat{T}_{I,\sim})
$$

is also left cofinal (Lemma T.4.1.3.2), and therefore a weak homotopy equivalence.

Define a functor $U_{I,\sim}^0 : \mathcal{E}_a \to \text{Top}$ by the formula

$$
U_{I,\sim}^0((m), \rho) = \{ \lambda \in \text{Hom}_{\text{Set}}(\langle m \rangle^\circ, \pi_0 I) : (\forall i \in \langle a \rangle^\circ)(\pi_1(p(i)) \in \lambda(\rho(i))) \}.
$$

We have a commutative diagram

$$
\begin{array}{ccc}
\chi \times \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0) \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}) & \xrightarrow{F} & \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}) \\
\downarrow & & \downarrow \text{F} \\
\chi & \xrightarrow{F_a} & \text{Un}_n \text{Sing}(\hat{T}_{I,\sim}^0).
\end{array}
$$

We will complete the proof by showing that the upper horizontal map is an equivalence of $\infty$-categories. Unwinding the definitions, we deduce easily that this will be true if $F_0$ is a categorical equivalence. The vertical maps are right fibrations; it will therefore suffice to show that $F$ induces a homotopy equivalence between the fibers of the vertical maps. This amounts to the following assertion:

(*) For every object $(W, \rho) = ((\langle m_1 \rangle, \ldots, \langle m_b \rangle), \rho) \in \mathcal{E}_a$ having image $(E, \rho) = ((\langle m_1 \rangle, \ldots, \langle m_b \rangle), \rho)$ in $\mathcal{E}_a$, if $\eta \in \hat{T}_{I,\sim}^0(W, \rho)$ determines an isomorphism $\langle b \rangle^\circ \simeq \pi_0 I$ having image $\eta' \in U_{I,\sim}^0(E, \rho)$, then the induced map

$$
\gamma : \text{Sing}(\hat{T}_{I,\sim}(W) \times \hat{T}_{I,\sim}^0(W) \{ \eta \}) \to \text{Sing}(\hat{T}_{I,\sim}(E) \times U_{I,\sim}^0(E) \{ \eta' \})
$$

is a homotopy equivalence.

Let $X$ denote the product $\prod_{1 \leq i \leq m} \text{Rect}(\square^1, I_i)$, where $I_1$ denotes the connected component of $I$ which is the image of $i \in \langle m \rangle^\circ$ under the map $\eta_0 : \langle m \rangle^\circ \to \pi_0 I$. Let $U$ denote the open subset of $X$ consisting of those sequences of embeddings $(f_i)_{1 \leq i \leq m}$ having the property that $\pi_1(p(j)) \in f_1(\rho(j))$ for $1 \leq j \leq a$. We note that $\gamma$ is the product of an identity map with the inclusion of a point into $\text{Sing}(U)$. We complete the proof by observing that $U$ is contractible (Lemma 5.1.1.3).
5.1.4 Comparison of Tensor Products

Let $R$ be a commutative ring, and let $\mathcal{C}$ denote the category of $R$-modules. Then $\mathcal{C}$ inherits a symmetric monoidal structure, which can be described in (at least) two different ways:

(a) Let $M$ and $N$ be $R$-modules. Then we can regard $M$ as a right $R$-module and $N$ as a left $R$-module, and consider the relative tensor product $M \otimes_R N$.

(b) The absolute tensor product $M \otimes N$ can be viewed as a module over the tensor product $R \otimes R$. The relative tensor product $M \otimes_R N$ is the $R$-module determined by base change of $M \otimes N$ along the ring homomorphism $m : R \otimes R \to R$ encoding the multiplication on $R$.

These two constructions agree: that is, there is a canonical isomorphism

$$M \otimes_R N \simeq (M \otimes N) \otimes_{R \otimes R} R.$$

Our goal in this section is to prove a generalization of this assertion, where the ordinary category of abelian groups is replaced by a symmetric monoidal $\infty$-category $\mathcal{C}$.

We begin by formulating a somewhat more general problem. Let $k \geq 1$ be an integer, and let $A$ be an $E_k$-algebra object of a symmetric monoidal $\infty$-category $\mathcal{C}$. We can then consider the $\infty$-category $\text{Mod}^E_A(\mathcal{C})$ of $E_k$-modules over $A$ (see §3.3.3). In good cases, $\text{Mod}^E_A(\mathcal{C})$ inherits the structure of an $E_k$-monoidal $\infty$-category (Theorem 3.4.4.2). On the other hand, we can regard $A$ as an associative algebra object of $\mathcal{C}$ using the forgetful functor

$$\text{Alg}^E_{E_k}(\mathcal{C}) \to \text{Alg}^E_k(\mathcal{C}) \simeq \text{Alg}(\mathcal{C}),$$

so that we can consider the $\infty$-category $\text{RMod}_A(\mathcal{C})$ of right $A$-module objects of $\mathcal{C}$. It follows from Corollary 4.8.5.20 that (under mild hypotheses) we can regard $\text{RMod}_A(\mathcal{C})$ as an $E_k$-monoidal $\infty$-category. Our main goal in this section is to show that (under the same hypotheses) there is an $E_k$-monoidal $\infty$-category $\text{Mod}^E_{\mathcal{C}}(\mathcal{C})$ and consider the relative tensor product $\text{RMod}_A(\mathcal{C}) \otimes_{\text{Mod}^E_{\mathcal{C}}(\mathcal{C})} \text{Mod}^E_{\mathcal{C}}(\mathcal{C})$.

We begin by setting up a bit of notation.

**Notation 5.1.4.1.** Let $p : N(\Delta)^{op} \to \text{Ass}^\otimes$ be as in Construction 4.1.2.5 and let $E_1 \to \text{Ass}^\otimes$ be the equivalence of Example 5.1.0.7. We let $\text{Ass}^\otimes$ denote the fiber product $N(\Delta)^{op} \times_{\text{Ass}^\otimes} E_1$, so that the projection map $\text{Ass}^\otimes \to N(\Delta)^{op}$ is a trivial Kan fibration.

Let $N(\Delta)^{op} \times \Delta^1 \to \mathcal{M}^\otimes$ be defined as in Remark 4.2.2.8 and set

$$\mathcal{X} = (N(\Delta)^{op} \times \Delta^1) \times_{\mathcal{M}^\otimes} (\mathcal{M}^\otimes \times_{\text{Ass}^\otimes} E_1).$$

There is a unique vertex $x \in \mathcal{X}$ lying over the initial object $[0], 0 \in N(\Delta)^{op} \times \Delta^1$. We let $\mathcal{L}M^\square$ denote the $\infty$-category $\mathcal{X}^{\square}/$. Example 5.1.0.7 implies that the map $\mathcal{X} \to N(\Delta)^{op} \times \Delta^1$ is a trivial Kan fibration, so that $x \in \mathcal{X}$ is an initial object and therefore the map $\mathcal{L}M^\square \to N(\Delta)^{op} \times \Delta^1$ is also a trivial Kan fibration. Moreover, the fiber product $\mathcal{L}M^\square \times_{\Delta^1} \{1\}$ is isomorphic to $\text{Ass}^\otimes$.

We will say that a morphism $f$ in $\text{Ass}^\otimes$ or $\mathcal{L}M^\square$ is *inert* if its image in $\mathcal{L}M^\square$ is inert.

**Construction 5.1.4.2.** Let $S$ be a simplicial set, and let $\mathcal{C}^\otimes \to E_1 \times S$ be an coCartesian $S$-family of $E_1$-monoidal $\infty$-categories. We let $\text{Alg}^\square(\mathcal{C})$ denote the full subcategory of

$$\text{Fun}_{E_1}(\text{Ass}^\otimes, \mathcal{C}^\otimes) \times_{\text{Fun}(\text{Ass}^\otimes, S)} S$$

spanned by those vertices which correspond to a vertex $s \in S$ and a map $\text{Ass}^\otimes \to \mathcal{C}^\otimes$ which carries every inert morphism in $\text{Ass}^\otimes$ to an inert morphism in $\mathcal{C}^\otimes$. We let $\text{RMod}^\square(\mathcal{C})$ denote the full subcategory of

$$\text{Fun}_{E_1}(\mathcal{L}M^\square, \mathcal{C}^\otimes) \times_{\text{Fun}(\mathcal{L}M^\square, S)} S$$

spanned by those vertices which correspond to a vertex $s \in S$ and a map $\mathcal{L}M^\square \to \mathcal{C}^\otimes$ which carries inert morphisms in $\mathcal{L}M^\square$ to inert morphisms in $\mathcal{C}^\otimes$. 

**Remark 5.1.4.3.** Let $C^0 \to E_1^\otimes \times S$ be a coCartesian $S$-family of $E_1$-monoidal $\infty$-categories. It follows from Proposition T.3.1.2.1 that the projection maps $p : \Alg^\otimes(C) \to S$, $q : \RMod^\otimes(C) \to S$ are coCartesian fibrations. Moreover, the restriction map $\RMod^\otimes(C) \to \Alg^\otimes(C)$ carries $q$-coCartesian morphisms to $p$-coCartesian morphisms.

**Example 5.1.4.4.** Let $C^0 \to \Ass^\otimes \times S$ be a coCartesian $S$-family of monoidal $\infty$-categories, let $C^0 = C^0_0 \times_{\Ass^\otimes} E_1^\otimes$, and let $M^\otimes = C^0_0 \times_{\Ass^\otimes} \RMod^\otimes$. Let $\Alg(C_0)$ and $\RMod(M)$ be defined as in Notation 4.8.3.11. Composition with the forgetful functors $\Ass^\otimes \to \Ass$ and $\LMod \to \LMod$ determines restriction maps that fit into a commutative diagram

\[
\begin{array}{ccc}
\RMod(M) & \longrightarrow & \RMod^\otimes(C) \\
\downarrow & & \downarrow \\
\Alg(C_0) & \longrightarrow & \Alg^\otimes(C).
\end{array}
\]

Using Propositions 4.1.2.15, 4.2.2.11, and T.3.3.1.5, we deduce that the horizontal maps are categorical equivalences.

**Remark 5.1.4.5.** Let $q : C^0 \to E_1^\otimes \times S$ be a coCartesian $S$-family of $E_1$-monoidal $\infty$-categories. Using Example 5.1.0.7, we deduce that $q$ is equivalent to $C^0_0 \times_{\Ass^\otimes} E_1^\otimes$, for some coCartesian $S$-family of monoidal $\infty$-categories $C^0_0 \to E_1^\otimes \times S$. It follows that the $\infty$-categories $\RMod^\otimes(C)$ and $\Alg^\otimes(C)$ can be understood in terms of the constructions described in §4.8.3, as explained in Example 5.1.4.4.

**Construction 5.1.4.6.** Let $k \geq 1$, let $C^\otimes \to E_k^\otimes$ be a coCartesian fibration of $\infty$-operads and let $D^\otimes = C^\otimes \times_{E_k^\otimes(E_1^\otimes \times E_{k-1}^\otimes)}$, so that $D^\otimes \to E_1^\otimes \times E_{k-1}^\otimes$ is a $E_{k-1}$-family of $E_1$-monoidal $\infty$-categories. Let $A \in \Alg_{/E_k}(C)$, so that composition with $A$ determines a section $s$ of the coCartesian fibration $\Alg^\otimes(D) \to E_{k-1}^\otimes$. We let $\RMod_A^\otimes(C)$ denote the fiber product $E_{k-1}^\otimes \times_{\Alg^\otimes(D)} \RMod^\otimes(D)$.

Combining Remark 5.1.4.5, Example 5.1.4.4, and Lemma 4.8.3.15, we obtain the following:

**Proposition 5.1.4.7.** Let $k \geq 1$ and let $C^\otimes \to E_k^\otimes$ be a coCartesian fibration of $\infty$-operads. Assume that $C$ admits geometric realizations of simplicial objects and that the tensor product $C \times C \to C$ preserves geometric realizations of simplicial objects. Then the projection map $\RMod_A^\otimes(C) \to E_{k-1}^\otimes$ is a coCartesian fibration of $\infty$-operads.

**Remark 5.1.4.8.** In the situation of Construction 5.1.4.6, the $\infty$-category $C$ admits a monoidal structure and $A$ determines an algebra object $A' \in \Alg(C)$. We have a canonical equivalence of $\infty$-categories $\RMod_A^\otimes(C) \simeq \RMod_{A'}(C)$.

**Construction 5.1.4.9.** By construction, there is a canonical map $\LMod \times \Delta^1 \to E_1^\otimes$, which determines a functor $\LMod \to \Fun(\Delta^1, E_1^\otimes)$. Combining this with the bifunctor of $\infty$-operads $E_1^\otimes \times E_{k-1}^\otimes \to E_k^\otimes$ of Construction 5.1.2.1, we obtain a functor

\[
\gamma : \LMod \times E_{k-1}^\otimes \to \K_{E_{k}} \subseteq \Fun(\Delta^1, E_{k}^\otimes),
\]

where $\K_{E_{k}}$ denotes the full subcategory of $\Fun(\Delta^1, E_{k}^\otimes)$ spanned by the semi-inert morphisms (see Notation 3.3.2.1).

Suppose that $C^\otimes \to E_k^\otimes$ is a coCartesian fibration of $\infty$-operads and let $A \in \Alg_{/E_k}(C)$. Then composition with $\gamma$ determines a functor

\[
\Mod^\otimes_A(C) \times_{E_k^\otimes} E_{k-1}^\otimes \to \RMod_A^\otimes(C).
\]

We can now state our main result as follows:
5.1. DEFINITIONS AND BASIC PROPERTIES

**Theorem 5.1.4.10.** Let $k \geq 1$, and let $q : \mathcal{E}^\otimes \to \mathcal{E}_k^\otimes$ be a coCartesian fibration of $\infty$-operads. Assume that the $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, and that the tensor product on $\mathcal{C}$ preserves geometric realizations separately in each variable. Then for each $A \in \text{Alg}_{/ \mathcal{E}_k}(\mathcal{C})$, the functor

$$\text{Mod}^E_A(\mathcal{E})^\otimes \times_{\mathcal{E}_k^\otimes} \mathcal{E}_{k-1}^\otimes \to \text{RMod}_A^1(\mathcal{E})^\otimes$$

is an $\mathcal{E}_{k-1}$-monoidal functor.

**Corollary 5.1.4.11.** Let $\mathcal{E}^\otimes \to \text{N}(\text{Fin}_*)$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product on $\mathcal{C}$ preserves geometric realizations of simplicial objects. Let $A \in \text{CAlg}(\mathcal{C})$ and let $A'$ be the image of $A$ in $\text{CAlg}(\text{Alg}(\mathcal{C}))$. Then there is a canonical equivalence of symmetric monoidal $\infty$-categories

$$\text{Mod}_A(\mathcal{E})^\otimes \simeq \text{RMod}_{A'}(\mathcal{E})^\otimes,$$

where $\text{Mod}_A(\mathcal{E})^\otimes$ is the symmetric monoidal $\infty$-category of Theorem 4.5.2.1.

**Proof.** Let $D^\otimes = \mathcal{E}^\otimes \times_{\text{N}(\text{Fin}_*)}(\mathcal{E}_1^\otimes \times \text{N}(\text{Fin}_*))$, and regard $D^\otimes$ as a coCartesian $\text{N}(\text{Fin}_*)$-family of $E_1$-monoidal $\infty$-categories. The commutative algebra $A$ determines a section of the coCartesian fibration $\text{Alg}^\otimes(D) \to \text{N}(\text{Fin}_*)$, and set $E^\otimes = \text{RMod}^D(D) \times_{\text{Alg}^\otimes(D)} \text{N}(\text{Fin}_*)$. Arguing as in Example 5.1.4.4, we see that the forgetful functor $\mathcal{L}^D \to \mathcal{R}^D$ induces an equivalence $\text{RMod}_A(\mathcal{E})^\otimes \to \mathcal{E}^\otimes$ of symmetric monoidal $\infty$-categories. Combining the bifunctor of $\infty$-operads $\mathcal{E}^\otimes \times \text{N}(\text{Fin}_*) \to \text{N}(\text{Fin}_*)$ with the map $\mathcal{L}^D \to \text{Fun}(\Delta^1, E^\otimes)$ of Construction 5.1.4.9, we obtain a map $\gamma : \mathcal{L}^D \times \text{N}(\text{Fin}_*) \to \mathcal{X}_{\text{Comm}} \subseteq \text{Fun}(\Delta^1, \text{N}(\text{Fin}_*))$. Composition with $\gamma$ determines a functor $\theta : \text{Mod}_A(\mathcal{E})^\otimes \to \mathcal{E}^\otimes$. We will complete the proof by showing that $\theta$ is an equivalence of symmetric monoidal $\infty$-categories. Using Proposition 4.5.1.4, we deduce that the underlying map $\text{Mod}_A(\mathcal{E}) \to \mathcal{E}$ is an equivalence of $\infty$-categories. It will therefore suffice to show that the functor $\theta$ is symmetric monoidal. Since every morphism in $\text{N}(\text{Fin}_*)$ can be lifted to a morphism in $E_1^\otimes$, it suffices to show that the induced map

$$\phi : \text{Mod}_A(\mathcal{E})^\otimes \times_{\text{N}(\text{Fin}_*)} E_1^\otimes \to \mathcal{E}^\otimes \times_{\text{N}(\text{Fin}_*)} E_1^\otimes$$

is symmetric monoidal. Let $B$ be the image of $A$ in $\text{Alg}_{/ \mathcal{E}_k}(\mathcal{C})$. Then $\phi$ factors as a composition

$$\text{Mod}_A(\mathcal{E})^\otimes \times_{\text{N}(\text{Fin}_*)} E_1^\otimes \xrightarrow{\phi'} \text{Mod}_B^k(\mathcal{E})^\otimes \times_{\mathcal{E}_k^\otimes} \mathcal{E}_{k-1}^\otimes \xrightarrow{\phi''} \text{RMod}_B^1(\mathcal{E})^\otimes,$$

where Theorem 5.1.4.10 implies that $\phi''$ is an $E_1$-monoidal functor. The forgetful functor $\text{Mod}_B^k(\mathcal{E}) \to \text{Mod}_B^1(\mathcal{E})$ is conservative (Corollary 3.4.3.4) and $E_1$-monoidal (Theorem 5.1.3.2). It will therefore suffice to show that the composite functor $\text{Mod}_A(\mathcal{E})^\otimes \times_{\text{N}(\text{Fin}_*)} E_1^\otimes \to \text{Mod}_B^1(\mathcal{E})^\otimes$ is $E_1$-monoidal; this follows from Theorem 4.5.2.1 and Example 5.1.0.7.

The proof of Theorem 5.1.4.10 will require a simple combinatorial lemma.

**Lemma 5.1.4.12.** Let $\star : \Delta \times \Delta \to \Delta$ be the join functor, given by $([m], [n]) \mapsto [m] \star [n] \simeq [m + n + 1]$. Then the induced map

$$N(\Delta) \times N(\Delta) \to N(\Delta)$$

is right cofinal.

**Proof.** Using Theorem 4.1.3.1, we are reduced to proving the following: let $[n] \in \Delta$, and let $\ell = (\Delta \times \Delta) \times (\Delta_{[n]})$ be the category of triples $([m], [m'], \alpha : [m] \star [m'] \to [n])$. Then the simplicial set $N(\ell)$ is weakly contractible. Let $\mathcal{C}_0$ be the full subcategory of $\mathcal{C}$ spanned by those triples $([m], [m'], \alpha)$ for which $\alpha$ induces a bijection from $[m]$ to $\{0, 1, \ldots, i\}$ and a bijection from $[m']$ to $\{j, \ldots, n\}$ for some $0 \leq i \leq j \leq n$. The inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ admits a left adjoint, so that the map $N(\mathcal{C}_0) \to N(\mathcal{C})$ is a weak homotopy equivalence. We conclude by observing that $\mathcal{C}_0$ has an initial object, given by the triple $([0], [0], \alpha : [1] \to [n])$ with $\alpha(0) = 0$, $\alpha(1) = n$.

□
Proof of Theorem 5.1.4.10. It is easy to see that the functor
\[
\text{Mod}^k_A(\mathcal{E}) \otimes_{\mathcal{E}^\otimes_k} \mathcal{E}^\otimes_{k-1} \to \text{RMod}^\otimes_A(\mathcal{E})
\]
is a map of \(\infty\)-operads which preserves unit objects. If \(k = 1\), this completes the proof. For \(k \geq 2\), we note that every morphism in \(\mathcal{E}^\otimes_{k-1}\) is equivalent to the image of a morphism in \(\mathcal{E}^\otimes_1\). It therefore suffices to show that the induced functor \(\theta : \text{Mod}^k_A(\mathcal{E}) \otimes_{\mathcal{E}^\otimes_k} \mathcal{E}^\otimes_1 \to \text{RMod}^\otimes_A(\mathcal{E}) \otimes_{\mathcal{E}^\otimes_{k-1}} \mathcal{E}^\otimes_1\) is \(\mathcal{E}_1\)-monoidal. Let \(A'\) denote the image of \(A\) in \(\text{Alg}_{E_2/E_k}(\mathcal{E})\). The functor \(\theta\) factors as a composition
\[
\text{Mod}^k_A(\mathcal{E}) \otimes_{\mathcal{E}^\otimes_k} \mathcal{E}^\otimes_1 \otimes' \text{Mod}^k_A(\mathcal{E}) \otimes_{\mathcal{E}^\otimes_k} \mathcal{E}^\otimes_1 \otimes'' \text{RMod}^\otimes_A(\mathcal{E}) \otimes_{\mathcal{E}^\otimes_{k-1}} \mathcal{E}^\otimes_1,
\]
where \(\theta'\) is an \(\mathcal{E}_1\)-monoidal functor by Theorem 5.1.3.2. It will therefore suffice to show that \(\theta''\) is \(\mathcal{E}_1\)-monoidal. We may therefore replace \(A\) by \(A'\) and thereby reduce to the case \(k = 2\).

Let \(p : \text{Mod}^2_A(\mathcal{E}) \otimes \to \mathcal{E}^\otimes_2\) and \(p' : \text{RMod}^\otimes_A(\mathcal{E}) \otimes \to \mathcal{E}^\otimes_1\) be the projection maps. We wish to show that if \(\alpha\) is a \(p\)-coCartesian morphism in \(\text{Mod}^2_A(\mathcal{E}) \otimes\) whose image in \(\mathcal{E}^\otimes_2\) is contained in \(\mathcal{E}^\otimes_1\), then \(\theta'(\alpha)\) is a \(p'\)-coCartesian morphism in \(\text{RMod}^\otimes_A(\mathcal{E}) \otimes\). Since it suffices to show that \(\theta\) preserves tensor products of pairs of object, we may assume without loss of generality that \(\alpha\) covers the map \(\alpha_0 : (2) \to (1)\) in \(\mathcal{E}^\otimes_2\) corresponding to the rectilinear embedding
\[
\square^2 \times (2) \otimes \sim ((-1,0) \times (-1,1)) \coprod ((0,1) \times (-1,1)) \hookrightarrow \square^2.
\]
Then \(\alpha_0\) determines a map \(\Delta^1 \to \mathcal{E}^\otimes_2\). We let \(\mathcal{K}\) denote the fiber product \(\Delta^1 \times_{\mathcal{E}^\otimes_2} \mathcal{K}_{\mathcal{E}_2}\), so that \(\alpha\) determines a functor \(F : \mathcal{K} \to \mathcal{E}^\otimes\).

We now introduce an auxiliary construction. We define a topological category \(\mathcal{E}\) as follows:

(a) The set of objects of \(\mathcal{E}\) is given by \(\{X, Z\} \cup \{Y_n\}_{n \geq 0}\).

(b) Morphism spaces in \(\mathcal{E}\) are given by
\[
\text{Map}_\mathcal{E}(X, X) = \text{Map}_\mathcal{E}(Z, Z) = * \quad \text{Map}_\mathcal{E}(Z, Y_n) \simeq \text{Map}_\mathcal{E}(Z, X) \simeq \text{Map}_\mathcal{E}(Y_n, X) = \emptyset
\]
\[
\text{Map}_\mathcal{E}(X, Y_n) = \text{Rect}(\square^2 \times \{-\infty\}, \square^2 \times \{-\infty\}) \times \text{Rect}(\square^2 \times \{\infty\}, \square^2 \times \{\infty\})
\]
\[
\text{Map}_\mathcal{E}(X, Z) = \text{Rect}(\square^2 \times \{-\infty, \infty\}, \square^2)
\]
\[
\text{Map}_\mathcal{E}(Y_n, Z) = \text{Rect}(\square^2 \times \{-\infty, -n, -n+1, \ldots, n, \infty\}, \square^2).
\]
If \(m, n \geq 0\), then \(\text{Map}_\mathcal{E}(Y_m, Y_n)\) is the disjoint union, over all nondecreasing maps \(\beta : [n] \to [m]\), of the product of the spaces
\[
\text{Rect}(\square^2 \times \{-\infty, -m, \ldots, -\beta(n) + 1\}, \square^2 \times \{-\infty\})
\]
\[
\prod_{1 \leq i \leq n} \text{Rect}(\square^2 \times \{-\beta(i), \ldots, -\beta(i-1) + 1\}, \square^2 \times \{-i\})
\]
\[
\text{Rect}(\square^2 \times \{-\beta(0), \beta(0) + 1, \ldots, \beta(0)\}, \square^2 \times \{0\})
\]
\[
\prod_{1 \leq i \leq n} \text{Rect}(\square^2 \times \{\beta(i-1) + 1, \ldots, \beta(i)\}, \square^2 \times \{i\})
\]
\[
\text{Rect}(\square^2 \times \{\beta(n) + 1, \ldots, m, \infty\}, \square^2 \times \{\infty\}),
\]
(which we can regard as a subspace of the collection of all maps from \(\square^2 \times \{-\infty, -m, \ldots, m, \infty\}\) to \(\square^2 \times \{-\infty, -n, \ldots, n, \infty\}\)).

(c) Composition of morphisms is given by composition of rectilinear embeddings.
5.1. DEFINITIONS AND BASIC PROPERTIES

There is an evident forgetful functor $\psi : \mathcal{E} \to \mathbb{R}_2^\otimes$, and $\alpha_0$ lifts uniquely to a morphism $\pi_0 : X \to Z$ in $\mathcal{E}$. We define a topological subcategory $\mathcal{E}_0^0 \subseteq \mathcal{E}$, having the same objects as $\mathcal{E}$, as follows:

- A rectilinear embedding $f : \square^2 \times \{\infty, \infty\} \to \square^k$ belongs to $\text{Map}_{\mathcal{E}_0^0}(X, Z)$ if and only if there is a rectilinear embedding $f_0 : (-1, 1) \to (-1, 1)$ such that
  
  \[ f(s, t, -\infty) = \left(\frac{s-1}{2}, f_0(t)\right), \quad f(s, t, \infty) = \left(\frac{s+1}{2}, f_0(t)\right). \]

- A pair of rectilinear embeddings $f_- : \square^2 \times \{\infty\} \to \square^2 \times \{\infty\}$, $f_+ : \square^2 \times \{\infty\} \to \square^2 \times \{\infty\}$ belongs to $\text{Map}_{\mathcal{E}_0^0}(X, Y_n)$ if and only if there is a rectilinear embedding $f_0 : (-1, 1) \to (-1, 1)$ such that $f_+(s, t) = (s, f_0(t)) = f_-(s, t)$.

- A rectilinear embedding $f : \square^2 \times \{-\infty, -\infty, \ldots, -n, \infty\} \to \square^2$ belongs to $\text{Map}_{\mathcal{E}_0^0}(Y_n, Z)$ if and only if there exists a rectilinear embedding $f_0 : \square^1 \times \{-\infty, -\infty, \ldots, 0\} \to \square^1$ such that $f_0(t, i) < f_0(t, j)$ for $i < j$, and
  
  \[ f(s, t, i) = \begin{cases} 
  (s, f_0(t, i)), & \text{if } i < 0 \\
  (s, f_0(t, i)), & \text{if } i = 0 \\
  (s, f_0(t, i)), & \text{if } i > 0.
  \end{cases} \]

- If $f : \square^2 \times \{-\infty, -m, \ldots, m, \infty\} \to \square^2 \times \{-\infty, -n, \ldots, n, \infty\}$ is a morphism from $Y_m$ to $Y_n$ in $\mathcal{E}$ covering a map of linearly ordered sets $\beta : [n] \to [m]$, then $f$ belongs to $\mathcal{E}_0^0$ if and only if there exists a rectilinear embedding $f_0 : \square^1 \times \{-\infty, -m, \ldots, 0\} \to \square^1 \times \{-\infty, -n, \ldots, 0\}$ such that $f_0(t, i) < f_0(t, j)$ for $i < j$ and
  
  \[ f(s, t, i) = \begin{cases} 
  (s, f_0(t, i)), & \text{if } i < -\beta(0) \\
  (s, f_0(t, i)), & \text{if } -\beta(0) \leq i < 0 \\
  (s, f_0(t, i)), & \text{if } i = 0 \\
  (s, f_0(t, i)), & \text{if } 0 < i \leq \beta(0) \\
  (s, f_0(t, i)), & \text{if } \beta(0) < i.
  \end{cases} \]

Note that $\pi_0$ is a morphism from $X$ to $Z$ in $\mathcal{E}_0^0$. Let $\mathcal{E}^0$ be the full subcategory of $(N(\mathcal{E}_0^0)/Z)^X$ spanned by those diagrams of the form

\[
\begin{array}{ccc}
X & \xrightarrow{\pi_0} & Z \\
\uparrow & & \uparrow \\
Y_n & & \\
\end{array}
\]

There is an evident forgetful functor $\mathcal{E}^0 \to \text{N}(\Delta)^{op}$ which is an equivalence of $\infty$-categories. The functor $F : \mathcal{K} \to \mathcal{E}^0$ induces a functor $\sigma : \mathcal{E}^0 \to \mathcal{E}^0$. Using Lemma 4.8.3.15, we see that $\theta(\alpha)$ is $q$-coCartesian if and only if $\delta^0$ is an operadic $q$-colimit diagram.

We now define another topological subcategory $\mathcal{E}^v \subseteq \mathcal{E}$. Let $\sigma : \square^2 \to \square^2$ be the reflection given by $\sigma(s, t) = (-s, s)$.

- A rectilinear embedding $f : \square^2 \times \{-\infty, \infty\} \to \square^k$ belongs to $\text{Map}_{\mathcal{E}^v}(X, Z)$ if and only if there exist rectilinear embeddings $f_0, f_1 : \square^1 \to \square^1$
  
  \[ f(s, t, -\infty) = \left(-\frac{f_0(-s) - 1}{2}, f_1(t)\right), \quad f(s, t, \infty) = \left(\frac{f_0(s) + 1}{2}, f_1(t)\right). \]

- A pair of rectilinear embeddings $f_- : \square^2 \times \{-\infty\} \to \square^2 \times \{-\infty\}$, $f_+ : \square^2 \times \{\infty\} \to \square^2 \times \{\infty\}$ belongs to $\text{Map}_{\mathcal{E}^v}(X, Y_n)$ if and only if $f_+ \circ \sigma = \sigma \circ f_-$.
Let $\pi_0, \pi_1 : \square^2 \to \square^1$ be the projection onto the first and second factors, respectively. A rectilinear embedding $f : \square^2 \times \{\infty, -n, \ldots, n, \infty\} \to \square^2$ belongs to $\Map_{\mathcal{E}}(X_m, Z)$ if and only if $\sigma f(s, t, i) = f(-s, t, -i)$. $\pi_1 f(s, t, i) < \pi_1 f(s', t', i')$ whenever $i < i' \leq 0$, and $\pi_0 f(s, t, i) < 0$ for $i < 0$ (so that $\pi_0 f(s, t, i) > 0$ for $i > 0$).

If $f : \square^2 \times \{\infty, -m, \ldots, m, \infty\} \to \square^2 \times \{\infty, -n, \ldots, n, \infty\}$ is a morphism from $Y_m$ to $Y_n$ in $\mathcal{E}$ covering a map of linearly ordered sets $\beta : [n] \to [m]$ given by a collection of maps $\{f_i : \square^2 \to \square^2\}_{i \in \{-\infty, -m, \ldots, m, \infty\}}$, then $f$ belongs to $\mathcal{E}^v$ if and only if $\sigma \circ f_i = f_{-i} \circ \sigma$ and $\pi_1 f_i(s, t) < \pi_1 f_i(s', t')$ whenever $i < i' \leq 0$ and $f$ carries $\square^2 \times \{i\}$ and $\square^2 \times \{i'\}$ to the same connected component of $\square^2 \times \{\infty, -n, \ldots, n, \infty\}$.

Note that $\mathcal{E}^v$ contains $\mathcal{E}^0$, and that the inclusion $\mathcal{E}^0 \hookrightarrow \mathcal{E}^v$ is a weak equivalence of topological categories. Let $\mathcal{X}^v$ be the full subcategory of $(\mathcal{N}(\mathcal{E}^v)/Z)^X$ spanned by those diagrams of the form

\[
Y_n \xrightarrow{\pi_0} X \xrightarrow{\pi_0} Z.\]

Then $F$ determines a functor $\delta^v : (\mathcal{X}^v)^\circ \to \mathcal{C}^\circ$. Since the inclusion $\mathcal{X}^0 \hookrightarrow \mathcal{X}^v$ is a categorical equivalence, we are reduced to proving that $\delta^v$ is an operadic $q$-colimit diagram.

We define another subcategory $\mathcal{E}^h \subseteq \mathcal{E}$ as follows:

- A rectilinear embedding $f : \square^2 \times \{\infty\} \to \square^k$ belongs to $\Map_{\mathcal{E}^h}(X, Z)$ if and only if it belongs to $\mathcal{E}^v$.

- A pair of rectilinear embeddings $f_- : \square^2 \times \{\infty\} \to \square^2 \times \{\infty\}$ belongs to $\Map_{\mathcal{E}^h}(X, Y_n)$ if and only if $f_+ \circ \sigma = \sigma \circ f_-$.

- A rectilinear embedding $f : \square^2 \times \{\infty, -n, \ldots, n, \infty\} \to \square^2$ belongs to $\Map_{\mathcal{E}^h}(Y_n, Z)$ if and only if $\sigma f(s, t, i) = f(-s, t, -i)$ and $\pi_0 f(s, t, i) < \pi_0 f(s', t', i')$ whenever $i < i' \leq 0$ and $f$ carries $\square^2 \times \{i\}$ and $\square^2 \times \{i'\}$ to the same component of $\square^2 \times \{\infty, -n, \ldots, n, \infty\}$.

If $f : \square^2 \times \{-\infty, -m, \ldots, m, \infty\} \to \square^2$ is a morphism from $Y_m$ to $Y_n$ in $\mathcal{E}$ covering a map of linearly ordered sets $\beta : [n] \to [m]$ given by a collection of maps $\{f_i : \square^2 \to \square^2\}_{i \in \{-\infty, -m, \ldots, m, \infty\}}$, then $f$ belongs to $\mathcal{E}^v$ if and only if $\sigma \circ f_i = f_{-i} \circ \sigma$ and $\pi_0 f_i(s, t) < \pi_0 f_i(s', t')$ whenever $i < i' \leq 0$ and $f$ carries $\square^2 \times \{i\}$ and $\square^2 \times \{i'\}$ to the same component of $\square^2 \times \{-\infty, -n, \ldots, n, \infty\}$.

Let $\mathcal{E}^{h,v} = \mathcal{E}^h \cap \mathcal{E}^v$. We observe that the inclusions

\[\mathcal{E}^v \hookrightarrow \mathcal{E}^{h,v} \hookrightarrow \mathcal{E}^v\]

are weak equivalences of topological categories. Let $\mathcal{X}^h$ be the full subcategory of $(\mathcal{N}(\mathcal{E}^h)/Z)^X$ spanned by those diagrams of the form

\[
Y_n \xrightarrow{\pi_0} X \xrightarrow{\pi_0} Z,\]

and let $\mathcal{X}^{h,v}$ be defined similarly. Then $F$ determines a functor $\delta^h : (\mathcal{X}^h)^\circ \to \mathcal{C}^\circ$. Since $\delta^h | (\mathcal{X}^{h,v})^\circ = \delta^v | (\mathcal{X}^{h,v})^\circ$ and the inclusions $\mathcal{X}^h \hookrightarrow \mathcal{X}^{h,v} \hookrightarrow \mathcal{X}^v$ are categorical equivalences, we conclude that $\delta^v$ is an operadic $q$-colimit diagram if and only if $\delta^h$ is an operadic $q$-colimit diagram.
Let $E^1$ be the topological subcategory of $E^h$ whose morphisms are given by rectilinear embeddings which commute with projection onto the second coordinate. The inclusion $E^1 \hookrightarrow E^h$ is a weak equivalence of topological categories. Let $X^1$ be the full subcategory of $(N(E^1)/Z)^X$ spanned by those diagrams of the form

$$
\begin{array}{c}
Y_n \\
\downarrow \alpha_0 \\
X \\
\downarrow \pi_0 \\
Z,
\end{array}
$$

so that the inclusion $X^1 \rightarrow X^h$ is a categorical equivalence. We are therefore reduced to proving that $\delta^1 = \delta^h|\langle X^1 \rangle^p$ is an operadic $q$-colimit diagram.

Let $\mathcal{Y}$ denote the full subcategory of $((E^1)_1)\langle 1 \rangle \langle 2 \rangle / \langle 2 \rangle$ spanned by those diagrams $\langle 2 \rangle \gamma' \downarrow \downarrow \langle 1 \rangle$ such that $\gamma$ is semi-inert, $\gamma'$ is active, and image of $\gamma$ contains the smallest and largest elements of $\langle n \rangle^p$ (with respect to the ordering induced by $\gamma'$). The map $\delta^1$ factors as a composition

$$(\langle X^1 \rangle)^p \rightarrow \mathcal{Y}^p \delta' \rightarrow \mathcal{C}.$$

Since $\alpha$ is $p$-coCartesian, the proof of Theorem 5.1.3.2 shows that $\delta'$ is an operadic $q$-colimit diagram. It will therefore suffice to show that the map $X^1 \rightarrow \mathcal{Y}$ is left cofinal. We have a commutative diagram of $\infty$-categories

$$
\begin{array}{c}
\mathcal{X}^1 \\
\downarrow \\
N(\Delta)^{op} \xrightarrow{u} N(\Delta)^{op}
\end{array}
$$

where the vertical maps are categorical equivalences and $u$ is the functor given by $[n] \mapsto [n] \ast [n]^{op} \simeq [2n + 1]$. The functor $u$ factors as a composition

$$
N(\Delta)^{op} \xrightarrow{u'} N(\Delta)^{op} \times N(\Delta)^{op} \xrightarrow{u''} N(\Delta)^{op} \times N(\Delta)^{op} \xrightarrow{u'''} N(\Delta)^{op}.
$$

The map $u'$ is left cofinal by Lemma T.5.5.8.4, the map $u''$ is an isomorphism (given by order-reversal on the second coordinate), and the map $u'''$ is induced by the join operation which is a left cofinal functor (Lemma 5.1.4.12). It follows that $u$ is left cofinal so that $X^1 \rightarrow \mathcal{Y}$ is also left cofinal, as desired.

5.2 Bar Constructions and Koszul Duality

Let $X$ be a topological space equipped with a base point $x \in X$, let $k$ be a positive integer, and let $\Omega^k X = \{f : ([0, 1]^k, \partial[0, 1]^k) \rightarrow (X, x)\}$ be the $k$-fold loop space of $X$. Then $\Omega^k X$ can be equipped with action of the topological operad $E_k$. If $X$ is $k$-connective, then it is possible to reconstruct $X$ (up to weak homotopy equivalence) from $\Omega^k X$ together with its $E_k$-algebra structure (see Theorem 5.2.6.15). More precisely, one can recover $X$ by applying an iterated bar construction to the space $\Omega^k X$. Our goal in this section is to study the iterated bar construction and the closely related theory of Koszul duality for $E_k$-algebras.
Let us begin by considering the case $k = 1$. For any pointed topological space $X$, the loop space $G = \Omega X$ can be regarded as a group object in the $\infty$-category of spaces. If $X$ is connected, then it can be recovered as the classifying space of $G$: that is, the geometric realization of the simplicial space

$$\cdots \rightarrow G \times G \rightarrow G \rightarrow \ast$$

which encodes the multiplication on $G$. If we regard the $\infty$-category $S$ as endowed with the symmetric monoidal structure given by the Cartesian product, then this classifying space can be described as the relative tensor product $\ast \otimes_{G} \ast$, where we regard $G$ as an associative algebra object of $S$ and the one-point space $\ast$ as a left and right module over $G$.

The above construction makes sense in much greater generality. Let $\mathcal{C}$ be a monoidal $\infty$-category with unit object $\mathbf{1}$ and let $A$ be an algebra object of $\mathcal{C}$. Suppose that $A$ is equipped with an augmentation: that is, a morphism $\epsilon : A \rightarrow \mathbf{1}$ in $\text{Alg}(\mathcal{C})$. Let us assume further that the $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product

$$\otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$$

preserves geometric realizations of simplicial objects, so that the relative tensor product $\mathbf{1} \otimes_A \mathbf{1}$ is well-defined. We will denote this tensor product by $\text{Bar}(A)$ and refer to it as the bar construction on the augmented algebra $A$.

Our goal in §5.2.2 is to study the bar construction $A \mapsto \text{Bar}(A)$ and establish some of its basic properties. The most important of these properties is that (under mild hypotheses) it carries augmented algebra objects of $\mathcal{C}$ to augmented coalgebra objects of $\mathcal{C}$: that is, augmented algebra objects of the opposite $\infty$-category $\mathcal{C}^{\text{op}}$. To study this phenomenon, we will need to understand the relationship between the monoidal structure on $\mathcal{C}$ and the induced monoidal structure on $\mathcal{C}^{\text{op}}$. To this end, in §5.2.1 we will introduce another $\infty$-category $\text{TwArr}(\mathcal{C})$ called the twisted arrow $\infty$-category of $\mathcal{C}$. By definition, the objects of $\text{TwArr}(\mathcal{C})$ are morphisms $f : C \rightarrow D$ in $\mathcal{C}$, with a morphism from $(f : C \rightarrow D)$ to $(f' : C' \rightarrow D')$ given by a commutative diagram

$$
\begin{array}{ccc}
C & \overset{f}{\rightarrow} & D \\
\downarrow & & \uparrow \\
C' & \overset{f'}{\rightarrow} & D'.
\end{array}
$$

Any monoidal structure on $\mathcal{C}$ determines a monoidal structure on $\text{TwArr}(\mathcal{C})$ (Example 5.2.2.23), and the construction

$$(f : C \rightarrow D) \mapsto (C, D)$$

determines a monoidal functor from $\text{TwArr}(\mathcal{C})$ to $\mathcal{C} \times \mathcal{C}^{\text{op}}$. We will see that the construction

$$(C, D) \mapsto \text{Alg}(\text{TwArr}(\mathcal{C})) \times_{\text{Alg}(\mathcal{C}) \times \text{Alg}(\mathcal{C}^{\text{op}})} \{(C, D)\}$$

determines a functor $\chi : \text{Alg}(\mathcal{C})^{\text{op}} \times \text{Alg}(\mathcal{C}^{\text{op}})^{\text{op}} \rightarrow S$. Our main result asserts that if the unit object $\mathbf{1} \in \mathcal{C}$ is final, then for each $A \in \text{Alg}(\mathcal{C})$ the functor $B \mapsto \chi(A, B)$ is representable by an object $B_0 \in \text{Alg}(\mathcal{C}^{\text{op}})$, and that the image of $B_0$ in $\mathcal{C}^{\text{op}}$ can be identified with the bar construction $\text{Bar}(A)$ (Theorem 5.2.2.17). The hypothesis that the unit object $\mathbf{1}$ be final is mainly for convenience, since it allows us to ignore the distinction between algebra objects of $\mathcal{C}$ and augmented algebra objects of $\mathcal{C}$; we will discuss the general case (where we do not assume that $\mathbf{1}$ is final) in §5.2.4.

Suppose now that the symmetric monoidal structure on $\mathcal{C}$ is symmetric. Then the bar construction $A \mapsto \text{Bar}(A) = 1 \otimes_A 1$ is a symmetric monoidal functor. In particular, if $A$ is an (augmented) $\mathbb{E}_k$-algebra object of $\mathcal{C}$ for $k > 0$, then we can regard $A$ as an (augmented) $\mathbb{E}_{k-1}$-algebra object of $\text{Alg}(\mathcal{C})$ so that $\text{Bar}(A)$ inherits the structure of an (augmented) $\mathbb{E}_{k-1}$-algebra object of $\mathcal{C}$. Using this observation, we can define an iterated bar construction $\text{Bar}^{(k)}$ for (augmented) $\mathbb{E}_k$-algebras using the formula

$$\text{Bar}^{(k)}(A) = \text{Bar}^{(k-1)}(\text{Bar}(A)).$$
In §5.2.3, we will show that the iterated bar construction $A \mapsto \text{Bar}^{(k)}(A)$ carries augmented $\mathbb{E}_k$-algebra objects of $\mathcal{C}$ to $\mathbb{E}_k$-coalgebra objects of $\mathcal{C}$. Moreover, we will see that the $\mathbb{E}_k$-coalgebra $\text{Bar}^{(k)}(A)$ is universal among those objects $B \in \mathcal{C}^{\text{op}}$ for which the pair $(A, B)$ can be lifted to an $\mathbb{E}_k$-algebra object of $\text{TwArr}(\mathcal{C})$: this gives a direct (non-recursive) definition of the iterated bar construction $\text{Bar}^{(k)}$ (and one which makes sense in slightly greater generality).

If the monoidal structure on $\mathcal{C}$ is symmetric, then the $\infty$-category $\text{Alg}_{\mathbb{E}_k}(\mathcal{C})$ of augmented $\mathbb{E}_k$-algebra objects of $\mathcal{C}$ inherits a monoidal structure. Given a pair of augmented $\mathbb{E}_k$-algebras $A, B$ in $\text{Alg}_{\mathbb{E}_k}(\mathcal{C})$ (Proposition 5.2.5.1 for a precise statement). Moreover, we will see that $\text{Bar}^{(k)}$ can be realized as the dual of the $\infty$-category of $\text{Alg}_{\mathbb{E}_k}(\mathcal{C})$-algebra objects of $\mathcal{C}$. Roughly speaking, the objects of $\text{TwArr}(\mathcal{C})$, called the twisted arrow $\infty$-category of $\mathcal{C}$, are morphisms $f : C \to D$ in $\mathcal{C}$, and morphisms in $\text{TwArr}(\mathcal{C})$ are given by commutative diagrams

$$
\begin{array}{ccc}
C & \xrightarrow{f} & D \\
\downarrow & & \downarrow \\
C' & \xrightarrow{f'} & D.
\end{array}
$$

We will give a precise definition of $\text{TwArr}(\mathcal{C})$ below (Construction 5.2.1.1) and prove that the construction $(f : C \to D) \mapsto (C, D)$ determines a right fibration $\lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}}$ (Proposition 5.2.1.3). The right fibration $\lambda$ is classified by a functor $\mu : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}$, which we can view in turn as a functor $\mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$. In [97], we gave an explicit construction of $\mu$, which does not rely on the theory of simplicial categories.

Our goal in this section is to give another construction of $\mathcal{C}$ to its Koszul dual can be regarded as a special case of the formation of centralizers, which we will study in §5.3 (see Example 5.3.1.5).

In §5.2.6, we will specialize to the case where $\mathcal{C}$ is the $\infty$-category of spaces (endowed with the symmetric monoidal structure given by the Cartesian product). In this case, we show that the iterated bar construction $\text{Bar}^{(k)}$ induces an equivalence from the $\infty$-category of grouplike $\mathbb{E}_k$-algebra objects of $\mathcal{C}$ to the $\infty$-category of $k$-connective pointed spaces (Theorem 5.2.6.15), and that this equivalence is homotopy inverse to the construction $X \mapsto \Omega^k X$ described above (Theorem 5.2.6.10).

### 5.2.1 Twisted Arrow $\infty$-Categories

Let $\mathcal{C}$ be an $\infty$-category. Recall that a functor $F : \mathcal{C}^{\text{op}} \to \mathcal{S}$ is representable if there exists an object $C \in \mathcal{C}$ and a point $\eta \in F(C)$ such that evaluation on $\eta$ induces a homotopy equivalence $\text{Map}_\mathcal{C}(C', C) \to F(C')$ for each $C' \in \mathcal{C}$. The $\infty$-categorical version of Yoneda’s lemma asserts that there is a fully faithful embedding $j : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ (Proposition T.5.1.3.1), whose essential image is the full subcategory of $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ spanned by the representable functors. The functor $j$ classifies a map $\mu : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}$, given at the level of homotopy categories by the formula $(C, D) \mapsto \text{Map}_\mathcal{C}(C, D)$. In [97], we gave an explicit construction of $\mu$ by choosing an equivalence of $\mathcal{C}$ with the nerve of a fibrant simplicial category (see §T.5.1.3).
We will show that this functor is equivalent to the Yoneda embedding (Proposition 5.2.1.11); in particular, it is fully faithful and its essential image is the collection of representable functors $F : \mathcal{C}^\text{op} \to \mathcal{S}$.

The twisted arrow $\infty$-category $\text{TwArr}(\mathcal{C})$ will play an important role when we discuss the bar construction in §5.2.2. For our applications, it is important to know that the construction $\mathcal{C} \mapsto \text{TwArr}(\mathcal{C})$ is functorial and commutes with small limits. To prove this, it will be convenient to describe $\text{TwArr}(\mathcal{C})$ by means of a universal property. We will provide two such descriptions at the end of this section (see Corollary 5.2.1.19).

**Construction 5.2.1.1.** If $I$ is a linearly ordered set, we let $I^\text{op}$ denote the same set with the opposite ordering. If $I$ and $J$ are linearly ordered sets, we let $I \ast J$ denote the coproduct $I \coprod J$, equipped with the unique linear ordering which restricts to the given linear orderings of $I$ and $J$, and satisfies $i \leq j$ for $i \in I$ and $j \in J$. Let $\Delta$ denote the category of combinatorial simplices: that is, the category whose objects sets of the form $[n] = \{0, 1, \ldots, n\}$ for $n \geq 0$, and whose morphisms are nondecreasing maps between such sets. Then $\Delta$ is equivalent to the larger category consisting of all nonempty finite linearly ordered sets. The construction $I \mapsto I \ast I^\text{op}$ determines a functor $Q$ from the category $\Delta$ to itself, given on objects by $[n] \mapsto [2n + 1]$. If $\mathcal{C}$ is a simplicial set (regarded as a functor $\mathcal{C} \to \mathcal{S}$), we let $\text{TwArr}(\mathcal{C})$ denote the simplicial set given by

$$[n] \mapsto \mathcal{C}(Q[n]) = \mathcal{C}([2n + 1]).$$

Let $\mathcal{C}$ be an $\infty$-category. By construction, the vertices of $\text{TwArr}(\mathcal{C})$ are edges $f : C \to D$ in $\mathcal{C}$. More generally, the $n$-simplices of $\text{TwArr}(\mathcal{C})$ are given by $(2n+1)$-simplices of $\mathcal{C}$, which it may be helpful to depict as diagrams

$$C_0 \leftarrow C_1 \rightarrow \cdots \rightarrow C_n \leftarrow D_0 \rightarrow \cdots \rightarrow D_n.$$

**Example 5.2.1.2.** Let $\mathcal{C}$ be an ordinary category. Then the simplicial set $\text{TwArr}(N(\mathcal{C}))$ is isomorphic to the nerve of an ordinary category, which we will will denote by $\text{TwArr}(\mathcal{C})$ (so that we have $\text{TwArr}(N(\mathcal{C})) \simeq N(\text{TwArr}(\mathcal{C}))$). Concretely, this category can be described as follows:

- The objects of $\text{TwArr}(\mathcal{C})$ are morphisms $f : C \to D$ in $\mathcal{C}$.
- A morphism from $(f : C \to D)$ to $(f' : C' \to D')$ in $\text{TwArr}(\mathcal{C})$ consists of a pair of morphisms $g : C \to C'$ and $h : D' \to D$ in $\mathcal{C}$ satisfying $f = h \circ f' \circ g$.

The construction $(f : C \to D) \mapsto (C, D)$ determines a forgetful functor from $\lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^\text{op}$. This functor exhibits $\text{TwArr}(\mathcal{C})$ as fibered in sets over $\mathcal{C} \times \mathcal{C}^\text{op}$, where the fiber over an object $(C, D) \in \mathcal{C} \times \mathcal{C}^\text{op}$ is given by the set of morphisms $\text{Hom}_\mathcal{C}(C, D)$. Consequently, $\text{TwArr}(\mathcal{C})$ can be identified with category given by applying the Grothendieck construction to the functor

$$\mathcal{C}^\text{op} \times \mathcal{C} \to \text{Set}$$

$$(C, D) \mapsto \text{Hom}_\mathcal{C}(C, D).$$

Let $\mathcal{C}$ be an arbitrary simplicial set. For any linearly ordered set $I$, we have canonical inclusions

$$I \hookrightarrow I \ast I^\text{op} \hookrightarrow I^\text{op}.$$

Composition with these inclusions determines maps of simplicial sets

$$\mathcal{C} \hookrightarrow \text{TwArr}(\mathcal{C}) \to \mathcal{C}^\text{op}.$$

**Proposition 5.2.1.3.** Let $\mathcal{C}$ be an $\infty$-category. Then the canonical map $\lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^\text{op}$ is a right fibration of simplicial sets. In particular, $\text{TwArr}(\mathcal{C})$ is also an $\infty$-category.
Proof. We must show that the map \( \lambda \) has the right lifting property with respect to the inclusion of simplicial sets \( \Lambda^n_i \hookrightarrow \Delta^n \) for \( 0 < i \leq n \). Unwinding the definitions, we must show that every lifting problem of the form

\[
\begin{array}{ccc}
K & \xrightarrow{f} & C \\
\downarrow & & \downarrow \\
\Delta^{2n+1} & \xrightarrow{\sigma} & \Delta^0
\end{array}
\]

admits a solution, where \( K \) denotes the simplicial subset of \( \Delta^{2n+1} \) consisting of those faces \( \sigma \) which satisfy one of the following three conditions:

- The vertices of \( \sigma \) are contained in the set \( \{0, \ldots, n\} \).
- The vertices of \( \sigma \) are contained in the set \( \{n + 1, \ldots, 2n + 1\} \).
- There exists an integer \( j \neq i \) such that \( 0 \leq j \leq n \) and neither \( j \) nor \( 2n + 1 - j \) is a vertex of \( \sigma \).

Since \( C \) is an \( \infty \)-category, it will suffice to show that the inclusion \( K \hookrightarrow \Delta^{2n+1} \) is an inner anodyne map of simplicial sets.

Let us say that a face \( \sigma \) of \( \Delta^{2n+1} \) is primary if it does not belong to \( K \) and does not contain any vertex in the set \( \{0, 1, \ldots, i - 1\} \), and secondary if it does not belong to \( K \) and does contain a vertex in the set \( \{0, 1, \ldots, i - 1\} \). Let \( S \) be the collection of all simplices of \( \Delta^{2n+1} \) which are either primary and do not contain the vertex \( i \), or secondary and do not contain the vertex \( 2n + 1 - i \). If \( \sigma \in S \), we let \( \sigma' \) denote the face obtained from \( \sigma \) by adding the vertex \( 2n + 1 - i \) if \( \sigma \) is primary, and by adding the vertex \( i \) if \( \sigma \) is secondary.

Note that every face of \( \Delta^{2n+1} \) either belongs to \( K \), belongs to \( S \), or has the form \( \sigma'_p \) for a unique \( \sigma \in S \).

Choose an ordering \( \{\sigma_1, \sigma_2, \sigma_3, \ldots, \sigma_m\} \) of \( S \) with the following properties:

- If \( p \leq q \), then the dimension of \( \sigma_p \) is less than or equal to the dimension of \( \sigma_q \).
- If \( p \leq q \), the simplices \( \sigma_p \) and \( \sigma_q \) have the same dimension, and \( \sigma_q \) is primary, then \( \sigma_p \) is also primary.

For \( 0 \leq q \leq m \), let \( K_q \) denote the simplicial subset of \( \Delta^{2n+1} \) obtained from \( K \) by adjoining the simplices \( \sigma_p \) and \( \sigma'_p \) for \( 1 \leq p \leq q \). We have a sequence of inclusions

\[ K = K_0 \hookrightarrow K_1 \hookrightarrow \cdots \hookrightarrow K_m = \Delta^{2n+1}. \]

It will therefore suffice to show that each of the maps \( K_{q-1} \hookrightarrow K_q \) is inner anodyne. Let \( d \) denote the dimension of the simplex \( \sigma'_q \). It now suffices to observe that there is a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\Lambda^d_j & \xrightarrow{f} & K_{q-1} \\
\downarrow & & \downarrow \\
\Delta^d & \xrightarrow{\sigma'_q} & K_q,
\end{array}
\]

where \( 0 < j < d \).

Remark 5.2.1.4. Let \( \mathcal{C} \) be an \( \infty \)-category containing a morphism \( f : C \to D \). Then \( f \) can be regarded as an object of the \( \infty \)-category \( \text{TwArr}(\mathcal{C}) \). Moreover, there is a canonical isomorphism of simplicial sets

\[ \text{TwArr}(\mathcal{C})/f \simeq \text{TwArr}(\mathcal{C}_{/f\downarrow D}); \]

here \( \mathcal{C}_{/f\downarrow D} \) denotes the \( \infty \)-category whose objects are commutative diagrams

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{f} & D \\
\downarrow & & \downarrow \\
X
\end{array}
\]
Definition 5.2.1.5. A pairing of ∞-categories is a triple \((\mathcal{C}, \mathcal{D}, \lambda : M \to \mathcal{C} \times \mathcal{D})\), where \(\mathcal{C}\) and \(\mathcal{D}\) are ∞-categories and \(\lambda\) is a right fibration of ∞-categories.

Remark 5.2.1.6. In the situation of Definition 5.2.1.5, we will generally abuse terminology by simply referring to the map \(\lambda : M \to \mathcal{C} \times \mathcal{D}\) as a pairing of ∞-categories. In this case, we will also say that \(\lambda\) is a pairing of \(\mathcal{C}\) with \(\mathcal{D}\).

Example 5.2.1.7. Let \(\mathcal{C}\) be an ∞-category. Proposition 5.2.1.3 asserts that the forgetful functor

\[ \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}} \]

is a pairing of ∞-categories.

Definition 5.2.1.8. Let \(\lambda : M \to \mathcal{C} \times \mathcal{D}\) be a pairing of ∞-categories, and let \(M \in \mathcal{M}\) be an object having image \((C, D) \in \mathcal{C} \times \mathcal{D}\). We will say that \(M\) is left universal if it is a final object of \(\mathcal{M} \times \mathcal{C}\) \{\(C\)\}, and right universal if it is a final object of \(\mathcal{M} \times \mathcal{D}\) \{\(D\)\}. We let \(\mathcal{M}^L\) and \(\mathcal{M}^R\) denote the full subcategories of \(\mathcal{M}\) spanned by the left universal and right universal objects, respectively. We say that \(\lambda\) is left representable if, for each object \(C \in \mathcal{C}\), there exists a left universal object \(M \in \mathcal{M}\) lying over \(C\). We will say that \(\lambda\) is right representable if, for each object \(D \in \mathcal{D}\), there exists a right universal object \(M \in \mathcal{M}\) lying over \(D\).

Construction 5.2.1.9. Let \(\lambda : M \to \mathcal{C} \times \mathcal{D}\) be a pairing of ∞-categories. As a right fibration, \(\lambda\) is classified by a functor \(\chi : \mathcal{C}^{\text{op}} \times \mathcal{D}^{\text{op}} \to S\). Note that \(\lambda\) is left representable if and only if, for each object \(C \in \mathcal{C}\), the restriction \(\chi_C : \lambda \downarrow \mathcal{C} \to \mathcal{D}^{\text{op}}\) is representable by an object \(D \in \mathcal{D}\). In this case, we can view \(\chi\) as a map \(\mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{D}^{\text{op}}, S)\) which is homotopic to a composition

\[ \mathcal{C}^{\text{op}} \xrightarrow{\Delta} \mathcal{D} \xrightarrow{j} \text{Fun}(\mathcal{D}^{\text{op}}, S) \]

for some essentially unique functor \(\Delta : \mathcal{C}^{\text{op}} \to \mathcal{D}\) (here \(j : \mathcal{D} \to \text{Fun}(\mathcal{D}^{\text{op}}, S)\) denotes the Yoneda embedding). We will refer to \(\Delta\) as the duality functor associated to \(\lambda\); it carries each object \(C \in \mathcal{C}\) to an object \(\Delta(C) \in \mathcal{D}\) which represents the functor \(\chi_C\) (that is, the image in \(\mathcal{D}\) of a left universal object \(M \in \mathcal{M}\) lying over \(C \in \mathcal{C}\)). More concretely, the functor \(\Delta\) is characterized by the existence of functorial homotopy equivalences

\[ \text{Map}_\mathcal{D}(D, \Delta(C)) \simeq \chi(C, D) \simeq \mathcal{M} \times \mathcal{C} \times \mathcal{D} \{\{C, D\}\}. \]

Similarly, if the pairing \(\lambda\) is right representable, then it determines a duality functor \(\Delta : \mathcal{D}^{\text{op}} \to \mathcal{C}\), which we will also refer to as the duality functor associated to \(\lambda\). If \(\lambda\) is both left and right representable, then \(\Delta\) is right adjoint to the duality functor \(\mathcal{D}^{\text{op}} : \mathcal{D} \to \mathcal{C}^{\text{op}}\).

Proposition 5.2.1.10. Let \(\mathcal{C}\) be an ∞-category. Then the pairing \(\lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}}\) of Proposition 5.2.1.3 is both left and right representable. Moreover, the following conditions on an object \(M \in \text{TwArr}(\mathcal{C})\) are equivalent:

(a) The object \(M\) is left universal (in the sense of Definition 5.2.1.8).

(b) The object \(M\) is right universal (in the sense of Definition 5.2.1.8).

(c) When viewed as a morphism in the ∞-category \(\mathcal{C}\), the object \(M\) is an equivalence.

Proof. We will prove that \((c) \Rightarrow (b)\). Then for every object \(C \in \mathcal{C}\), the identity morphism \(\text{id}_C\) is a right universal object of \(\text{TwArr}(\mathcal{C})\) lying over \(C \in \mathcal{C}^{\text{op}}\), which proves that \(\lambda\) is right representable. Since a right universal object of \(\text{TwArr}(\mathcal{C})\) lying over \(C \in \mathcal{C}^{\text{op}}\) is determined uniquely up to equivalence, we may also conclude that \((b) \Rightarrow (c)\). By symmetry, we can also conclude that \((a) \Leftrightarrow (c)\) and that the pairing \(\lambda\) is left representable.

Fix an object \(D \in \mathcal{C}^{\text{op}}\), and let \(\text{TwArr}(\mathcal{C})_D\) denote the fiber product \(\text{TwArr}(\mathcal{C}) \times \mathcal{C}^{\text{op}} \{D\}\). Then \(\lambda\) induces a right fibration of simplicial sets \(\lambda_D : \text{TwArr}(\mathcal{C})_D \to \mathcal{C}\). We wish to prove that if \(M\) is an object of \(\text{TwArr}(\mathcal{C})_D\) given by an equivalence \(f : C \to D\) in \(\mathcal{C}\), then \(M\) represents the right fibration \(\lambda_D\).
For every linearly ordered set $I$, there is an evident map of linearly ordered sets $I \star I^{op} \to I \star [0]$, depending functorially on $I$. Composing with these maps, we obtain a functor $\psi : C/\partial \to \TwArr(\mathcal{C})$. This map is bijective on vertices (vertices of both $C/\partial$ and $\TwArr(\mathcal{C})$ can be identified with edges $f : C \to D$ of the simplicial set $\mathcal{C}$). Since the right fibration $C/\partial \to \mathcal{C}$ is representable by any equivalence $f : C \to D$ (see the proof of Proposition T.4.4.4.5), it will suffice to show that the map $\psi$ is a categorical equivalence.

We now define an auxiliary simplicial set $M$ as follows. For every $[n] \in \Delta$, we let $M([n])$ denote the simplicial subset of $\mathcal{C}([n] \star [0] \star [n]^{op})$ consisting of those $(2n + 2)$-simplices of $\mathcal{C}$ whose restriction to $[0] \star [n]^{op}$ is the constant $(n + 1)$-simplex at the vertex $D$. The inclusions of linearly ordered sets

$$[n] \star [0] \hookrightarrow [n] \star [0] \star [n]^{op} \leftarrow [n] \star [n]^{op}$$

induce maps of simplicial sets

$$\mathcal{C}/\partial \stackrel{\phi}{\to} M \stackrel{\phi'}{\longrightarrow} \TwArr(\mathcal{C}).$$

The map $\psi : C/\partial \to \TwArr(\mathcal{C})$ can be obtained by composing $\phi'$ with a section of $\phi$. To prove that $\psi$ is a categorical equivalence, it will suffice to show that $\phi$ and $\phi'$ are categorical equivalences. We will complete the proof by showing that $\phi$ and $\phi'$ are trivial Kan fibrations.

We first show that $\phi$ is a trivial Kan fibration: that is, that $\phi$ has the right lifting property with respect to every inclusion $\partial \Delta^n \hookrightarrow \Delta^n$. Unwinding the definitions, we are reduced to solving a lifting problem of the form

$$\begin{array}{ccc}
K & \to & \mathcal{C} \\
\downarrow & & \downarrow \\
\Delta^n \star \Delta^0 \star \Delta^n & \to & \Delta^0
\end{array}$$

where $K$ denotes the simplicial subset of $\Delta^n \star \Delta^0 \star \Delta^n \simeq \Delta^{2n+2}$ spanned by $\Delta^n \star \Delta^0$, $\Delta^0 \star \Delta^n$, and $\Delta^I \star \Delta^0 \star \Delta^{I^{op}}$ for every proper subset $I \subsetneq [n]$. Since $\mathcal{C}$ is an $\infty$-category, it suffices to show that the inclusion $K \hookrightarrow \Delta^n \star \Delta^0 \star \Delta^n$ is a categorical equivalence.

Lemma T.5.4.5.10 implies that the composite map

$$(\Delta^n \star \Delta^0) \coprod_{\Delta^0} (\Delta^0 \star \Delta^n) \xrightarrow{i} K \to \Delta^n \star \Delta^0 \star \Delta^n$$

is a categorical equivalence. It will therefore suffice to show that the map $i$ is a categorical equivalence. Let $K_0$ denote the simplicial subset of $K$ spanned by those faces of the form $\Delta^I \star \Delta^0 \star \Delta^{I^{op}}$, where $I$ is a proper subset of $[n]$. We have a pushout diagram of simplicial sets

$$\begin{array}{ccc}
(\partial \Delta^n \star \Delta^0) \coprod_{\Delta^0} (\Delta^0 \star \partial \Delta^n) & \xrightarrow{i_0} & K_0 \\
\downarrow & & \downarrow \\
(\Delta^n \star \Delta^0) \coprod_{\Delta^0} (\Delta^0 \star \Delta^n) & \xrightarrow{i} & K.
\end{array}$$

Since the Joyal model structure is left proper, we are reduced to proving that the map $i_0$ is a categorical equivalence. We can write $i_0$ as a homotopy colimit of morphisms of the form

$$(\Delta^I \star \Delta^0) \coprod_{\Delta^0} (\Delta^0 \star \Delta^{I^{op}}) \to \Delta^I \star \Delta^0 \star \Delta^{I^{op}},$$

where $I$ ranges over all proper subsets of $[n]$. Since each of these maps is a categorical equivalence (Lemma T.5.4.5.10), we conclude that $i_0$ is a categorical equivalence as desired.

We now prove that $\phi'$ is a trivial Kan fibration. We must show that $\phi'$ has the right lifting property with respect to every inclusion of simplicial sets $\partial \Delta^n \hookrightarrow \Delta^n$. To prove this, we must show that every lifting
problem of the form

\[
\begin{array}{ccc}
L & \to & \mathcal{C} \\
\downarrow f_0 \quad & & \downarrow \\
\Delta^n \ast \Delta^0 \ast \Delta^n & \to & \Delta^0
\end{array}
\]

has a solution, where \(L\) denotes the simplicial subset of \(\Delta^n \ast \Delta^0 \ast \Delta^n \simeq \Delta^{2n+2}\) given by the union of \(\Delta^0 \ast \Delta^n\), \(\Delta^n \ast \Delta^n\), and \(K_0\), and \(f_0\) is a map whose restriction to \(\Delta^0 \ast \Delta^n\) is constant.

Let \(\sigma\) be a face of \(\Delta^{2n+2}\) which does not belong to \(L\). Let \(i(\sigma)\) denote the first vertex of \(\Delta^{2n+2}\) which belongs to \(\sigma\). Since \(\sigma\) does not belong to \(\Delta^0 \ast \Delta^n \subseteq L\), we must have \(i(\sigma) \leq n\). For \(j < i(\sigma)\), we have \(j \notin \sigma\). Since \(\sigma\) is not contained in \(K_0\), we conclude that \(2n + 2 - j \in \sigma\). Let us say that \(\sigma\) is large if it contains the vertex \(2n + 2 - i(\sigma)\), and small if it does not contain the vertex \(2n + 2 - i(\sigma)\). Let \(S\) be the collection of small faces of \(\Delta^{2n+2}\) (which are not contained in \(L\)). For each \(\sigma \in S\), we let \(\sigma'\) denote the face obtained from \(\sigma\) by adding the vertex \(2n + 2 - i(\sigma)\). Choose an ordering of \(S = \{\sigma_1, \sigma_2, \ldots, \sigma_m\}\) with the following properties:

(a) If \(p \leq q\), then the dimension of \(\sigma_p\) is less than or equal to the dimension of \(\sigma_q\).

(b) If \(p \leq q\) and the simplices \(\sigma_p\) and \(\sigma_q\) have the same dimension, then \(i(\sigma_q) \leq i(\sigma_p)\).

For \(0 \leq q \leq m\), let \(L_q\) denote the simplicial subset of \(\Delta^{2n+2}\) obtained from \(L\) by adding the faces \(\sigma_p\) and \(\sigma'_p\) for \(p \leq q\). We have a sequence of inclusions

\[
L_0 \subseteq L_1 \subseteq L_2 \subseteq \cdots \subseteq L_m = \Delta^{2n+2}.
\]

To complete the proof, it will suffice to show that the map \(f_0 : L_0 \to \mathcal{C}\) can be extended to a compatible sequence of maps \(\{f_q : L_q \to \mathcal{C}\}_{0 \leq q \leq m}\). We proceed by induction. Assume that \(q > 0\) and that \(f_{q-1} : L_{q-1} \to \mathcal{C}\) has already been constructed. Let \(d\) be the dimension of \(\sigma'_q\), and observe that there is a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\Lambda^d_{d-i(\sigma_q)} & \to & L_{q-1} \\
\downarrow & & \downarrow \\
\Delta^d & \to & L_q.
\end{array}
\]

Consequently, to prove the existence of \(f_q\), it will suffice to show that the map \(f_{q-1}|\Lambda^d_{d-i(\sigma_q)}\) can be extended to a \(d\)-simplex of \(\mathcal{C}\). Since \(d > i(\sigma_q)\), the existence of such an extension follows from the assumption that \(\mathcal{C}\) is an \(\infty\)-category provided that \(i(\sigma_q) > 0\). In the special case \(i(\sigma) = 0\), it suffices to show that the map \(f_{q-1}|\Lambda^d_d\) carries the final edge of \(\Lambda^d_d\) to an equivalence in \(\mathcal{C}\). This follows from our assumption that \(f_0|((\Delta^0 \ast \Delta^n))\) is a constant map (note that \(\sigma'_q\) automatically contains the vertices \(n + 1\) and \(2n + 2\), so that the final edge of \(\sigma'_q\) is contained in \(\Delta^0 \ast \Delta^n \subseteq \Delta^n \ast \Delta^0 \ast \Delta^n \simeq \Delta^{2n+2}\)).

**Proposition 5.2.1.11.** Let \(\mathcal{C}\) be an \(\infty\)-category, and let \(\chi : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}\) classify the right fibration \(\lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}}\). The map \(\mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})\) determined by \(\chi\) is homotopic to the Yoneda embedding (see §T.5.1.3).

**Remark 5.2.1.12.** Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}}\) be the pairing of Proposition 5.2.1.3. Proposition 5.2.1.10 implies that \(\lambda\) is right and left representable, so that Construction 5.2.1.9 yields a pair of adjoint functors

\[
\mathcal{D}_\lambda^{\text{op}} : \mathcal{C} \to \mathcal{C} \quad \mathcal{D}_\lambda : \mathcal{C} \to \mathcal{C}.
\]

Proposition 5.2.1.11 asserts that these functors are homotopic to the identity.
5.2. BAR CONSTRUCTIONS AND KOSZUL DUALITY

Proof: We begin by recalling the construction of the Yoneda embedding $\mathcal{C} \to \text{Fun}(\mathcal{C}^{op}, \mathcal{S})$. Choose a fibrant simplicial category $\mathcal{D}$ and an equivalence of $\infty$-categories $\psi : \mathcal{C} \to N(\mathcal{D})$. The construction $(D, D') \mapsto \text{Map}_{\mathcal{D}}(D, D')$ determines a simplicial functor $\mathcal{F} : \mathcal{D}^{op} \times \mathcal{D} \twoheadrightarrow \mathcal{Xan}$, where $\mathcal{Xan}$ denote the (simplicial) category of Kan complexes. Passing to homotopy coherent nerves, we obtain a functor

$$\mu : \mathcal{C} \times \mathcal{C}^{op} \to N(\mathcal{D}) \times N(\mathcal{D})^{op} \simeq N(\mathcal{D} \times \mathcal{D}^{op}) \to N(\mathcal{Xan}) = \mathcal{S}$$

which we can identify with Yoneda embedding $\mathcal{C} \to \text{Fun}(\mathcal{C}^{op}, \mathcal{S})$. We are therefore reduced to proving that the functor $\mu$ classifies the right fibration $\text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{op}$.

Let $\mathcal{E} : \text{Set}_{\Delta} \to \text{Cat}_{\Delta}$ denote the left adjoint to the simplicial nerve functor and let $\phi : \mathcal{C}[\mathcal{C} \times \mathcal{C}^{op}] \to \mathcal{D} \times \mathcal{D}^{op}$ be the equivalence of simplicial categories determined by $\psi$, and let

$$\text{Un}_{\phi} : \text{Set}_{\Delta} \times \mathcal{D} \to (\text{Set}_{\Delta})/\mathcal{C} \times \mathcal{C}^{op}$$

denote the unstraightening functor defined in §T.2.2.1. To complete the proof, it will suffice to construct an equivalence $\beta : \text{TwArr}(\mathcal{C}) \to \text{Un}_{\phi}(\mathcal{F})$ of right fibrations over $\mathcal{C} \times \mathcal{C}^{op}$.

We begin by constructing the map $\beta$. Let $\mathcal{E}$ be the simplicial category obtained from $\mathcal{D} \times \mathcal{D}^{op}$ by adjoining a new element $v$, with mapping spaces given by

$$\text{Map}_{\mathcal{E}}(v, (D, D')) = \emptyset, \quad \text{Map}_{\mathcal{E}}((D, D'), v) = \text{Map}_{\mathcal{D}}(D, D').$$

Unwinding the definitions, we see that giving the map $\beta$ is equivalent to constructing a map $\gamma : \text{TwArr}(\mathcal{C})^{op} \to N(\mathcal{E})$ carrying the cone point of $\text{TwArr}(\mathcal{C})$ to $v$ and such that $\gamma|_{\text{TwArr}(\mathcal{C})}$ is given by the composition

$$\text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{op} \to N(\mathcal{D} \times \mathcal{D}^{op}) \hookrightarrow N(\mathcal{E}).$$

To describe the map $\gamma$, it suffices to define the composite map

$$\gamma_{\sigma} : \Delta^{n+1} \xrightarrow{\sigma^{op}} \text{TwArr}(\mathcal{C})^{op} \xrightarrow{\gamma} N(\mathcal{E})$$

for every $n$-simplex $\sigma : \Delta^n \to \text{TwArr}(\mathcal{C})$. We will identify $\gamma_{\sigma}$ with a map of simplicial categories $\mathcal{C}[\Delta^{n+1}] \to \mathcal{E}$, carrying the final vertex of $\Delta^{n+1}$ to $v$ and given on $\mathcal{C}[\Delta^n]$ by the composite map

$$\mathcal{C}[\Delta^n] \xrightarrow{\sigma \times \sigma^{op}} \mathcal{C}[\mathcal{C}] \times \mathcal{C}[\mathcal{C}]^{op} \to \mathcal{D} \times \mathcal{D}^{op} \subseteq \mathcal{E}.$$

We can identify $\sigma$ with a map $\Delta^{2n+1} \to \mathcal{C}$, which induces a functor of simplicial categories $\nu_{\sigma} : \mathcal{C}[\Delta^{2n+1}] \to \mathcal{C}[\mathcal{C}] \to \mathcal{D}$.

To complete the definition of $\gamma_{\sigma}$, it suffices to describe the induced maps

$$\text{Map}_{\mathcal{E}[\Delta^{n+1}]}(i, n+1) \to \text{Map}_{\mathcal{E}}(\gamma_{\sigma}(i), v) = \text{Map}_{\mathcal{D}}(\nu_{\sigma}(i), \nu_{\sigma}(2n+1-i)).$$

for $0 \leq i \leq n$. These maps will be given by a composition

$$\text{Map}_{\mathcal{E}[\Delta^{n+1}]}(i, n+1) \xrightarrow{\alpha} \text{Map}_{\mathcal{E}[\Delta^{2n+1}]}(i, 2n+1-i) \xrightarrow{\beta} \text{Map}_{\mathcal{D}}(\nu_{\sigma}(i), \nu_{\sigma}(2n+1-i)).$$

Recall that for $0 \leq j \leq k \leq m$, the mapping space $\text{Map}_{\mathcal{E}[\Delta^{m}])(j,k)}$ can be identified with the nerve of the partially ordered collection of subsets of $[m]$ having infimum $j$ and supremum $k$ (see Definition T.1.1.5.1). Under this identification, $\alpha$ corresponds to the map of partially ordered sets given by

$$S \cup \{n+1\} \mapsto S \cup \{2n+1-j : j \in S\}.$$

It is not difficult to see that these maps determine a simplicial functor $\mathcal{C}[\Delta^{n+1}] \to \mathcal{E}$, giving a map of simplicial sets $\gamma_{\sigma} : \Delta^{n+1} \to N(\mathcal{E})$. The construction is functorial in $\sigma$, and therefore arises from the desired map $\gamma : \text{TwArr}(\mathcal{C})^{op} \to N(\mathcal{E})$. 
It remains to prove that $\beta$ is a homotopy equivalence. Since the maps

$$\text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}} \leftarrow \text{Un}_{\phi}(\mathcal{F})$$

are right fibrations, it will suffice to prove that $\beta$ induces a homotopy equivalence

$$\beta_{C,C'} : \text{TwArr}(\mathcal{C}) \times_{\mathcal{C} \times \mathcal{C}^{\text{op}}} \{ (C,C') \} \to (\text{Un}_{\phi}\mathcal{F}) \times_{\mathcal{C} \times \mathcal{C}'} \{ (C,C') \}$$

for every pair of objects $C,C' \in \mathcal{C}$. Consider the map

$$u : \mathcal{C}/C' \to \text{TwArr}(\mathcal{C}) \times_{\mathcal{C} \times \mathcal{C}^{\text{op}}} \{ C' \}$$

appearing in the proof of Proposition 5.2.1.10. Since $u$ induces a homotopy equivalence

$$\text{Hom}_{\mathcal{R}}(\mathcal{C},C') = \{ C \} \times_{\mathcal{C}/C'} \mathcal{C}/C' \to \text{TwArr}(\mathcal{C}) \times_{\mathcal{C} \times \mathcal{C}^{\text{op}}} \{ (C,C') \},$$

we are reduced to proving that the composite map

$$\text{Hom}_{\mathcal{R}}(\mathcal{C},C') \to \text{TwArr}(\mathcal{C}) \times_{\mathcal{C} \times \mathcal{C}^{\text{op}}} \{ (C,C') \} \to (\text{Un}_{\phi}\mathcal{F}) \times_{\mathcal{C} \times \mathcal{C}'} \{ (C,C') \}$$

is a homotopy equivalence. This follows from Proposition T.2.2.4.1.

Our next goal is to characterize the twisted arrow $\infty$-category $\text{TwArr}(\mathcal{C})$ by a universal property. In fact, we will give two such universal properties.

**Definition 5.2.1.13.** Let $\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ and $\lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}'$ be pairings of $\infty$-categories. A **morphism of pairings** from $\lambda$ to $\lambda'$ is a triple of maps

$$\alpha : \mathcal{C} \to \mathcal{C}' \quad \beta : \mathcal{D} \to \mathcal{D}' \quad \gamma : \mathcal{M} \to \mathcal{M}'$$

for which the diagram

$$\begin{array}{ccc}
\mathcal{M} & \xrightarrow{\gamma} & \mathcal{M}' \\
\downarrow{\lambda} & & \downarrow{\lambda'} \\
\mathcal{C} \times \mathcal{D} & \xrightarrow{\alpha \times \beta} & \mathcal{C}' \times \mathcal{D}'
\end{array}$$

commutes. We let $\text{CPair}_\Delta$ denote the category whose objects are pairings $(\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D})$ and whose morphisms are defined as above.

**Construction 5.2.1.14.** The category $\text{CPair}_\Delta$ of Definition 5.2.1.13 is equipped with a natural simplicial enrichment, where the mapping spaces $\text{Map}_{\text{CPair}_\Delta}(\lambda,\lambda')$ are characterized by the following universal property: for every simplicial set $K$, there is a canonical bijection between $\text{Hom}_{\text{Set}_\Delta}(K,\text{Map}_{\text{CPair}_\Delta}(\lambda,\lambda'))$ and the set of triples $(\alpha,\beta,\gamma)$ where $\alpha : K \times \mathcal{C} \to \mathcal{C}'$ is a map of simplicial sets carrying each edge of $K$ to an equivalence in $\text{Fun}(\mathcal{C},\mathcal{C}')$, $\beta : K \times \mathcal{D} \to \mathcal{D}'$ is a map of simplicial sets carrying each edge of $K$ to an equivalence in $\text{Fun}(\mathcal{D},\mathcal{D}')$, and $\gamma : K \times \mathcal{M} \to \mathcal{M}'$ is a map fitting into a commutative diagram

$$\begin{array}{ccc}
K \times \mathcal{M} & \xrightarrow{\gamma} & \mathcal{M}' \\
\downarrow{\lambda} & & \downarrow{\lambda'} \\
K \times K \times \mathcal{C} \times \mathcal{D} & \xrightarrow{\alpha \times \beta} & \mathcal{C}' \times \mathcal{D}'
\end{array}$$

(it then follows automatically that $\gamma$ carries each edge of $K$ to an equivalence in $\text{Fun}(\mathcal{M},\mathcal{M}')$). It is not difficult to see that the mapping spaces $\text{Map}_{\text{CPair}_\Delta}(\lambda,\lambda')$ are Kan complexes (see Lemma 5.2.1.23 below), so that the homotopy coherent nerve $N(\text{CPair}_\Delta)$ is an $\infty$-category. We will denote this $\infty$-category by $\text{CPair}$ and refer to it as the $\infty$-category of pairings of $\infty$-categories.
Remark 5.2.1.15. It follows from Proposition T.4.2.4.4 that CPair is equivalent to the full subcategory of Fun(\(\Lambda^n_2, \text{Cat}_{\infty}\)) spanned by those diagrams \(\mathcal{C} \leftarrow \mathcal{M} \to \mathcal{D}\) for which the induced map \(\mathcal{M} \to \mathcal{C} \times \mathcal{D}\) is equivalent to a right fibration. This subcategory is a localization of Fun(\(\Lambda^n_2, \text{Cat}_{\infty}\)); in particular, we can identify CPair with a full subcategory of Fun(\(\Lambda^n_2, \text{Cat}_{\infty}\)) which is closed under small limits.

Variant 5.2.1.16. Suppose that \(\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}\) and \(\lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}'\) are left representable pairings of \(\infty\)-categories. We will say that a morphism of pairings

\[
\begin{array}{c}
\mathcal{M} \xrightarrow{\gamma} \mathcal{M}' \\
\downarrow \quad \downarrow \\
\mathcal{C} \times \mathcal{D} \xrightarrow{\alpha \times \beta} \mathcal{C}' \times \mathcal{D}'
\end{array}
\]

is left representable if the functor \(\gamma\) carries left universal objects of \(\mathcal{M}\) to left universal objects of \(\mathcal{N}\). We let CPair\(_L^\ast\) denote the subcategory of CPair whose objects are left representable pairings of \(\infty\)-categories and whose morphisms are left representable morphisms of pairings. We will refer to CPair\(_L^\ast\) as the \(\infty\)-category of left representable pairings of \(\infty\)-categories.

Dually, if \(\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}\) and \(\lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}'\) are right representable pairings, then we say that a morphism of pairings

\[
\begin{array}{c}
\mathcal{M} \xrightarrow{\gamma} \mathcal{M}' \\
\downarrow \quad \downarrow \\
\mathcal{C} \times \mathcal{D} \xrightarrow{\alpha \times \beta} \mathcal{C}' \times \mathcal{D}'
\end{array}
\]

is right representable if \(\gamma\) carries right universal objects of \(\mathcal{M}\) to right universal objects of \(\mathcal{N}\). We let CPair\(_R^\ast\) denote the subcategory of CPair whose objects are right representable pairings of \(\infty\)-categories and whose morphisms are right representable morphisms of pairings. We will refer to CPair\(_R^\ast\) as the \(\infty\)-category of right representable pairings of \(\infty\)-categories.

The relevance of the left representability condition on a morphism of pairings can be described as follows:

Proposition 5.2.1.17. Let \(\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}\) and \(\lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}'\) be left representable pairings of \(\infty\)-categories, which induce functors \(\mathcal{D}_\lambda : \mathcal{C}^{\text{op}} \to \mathcal{D}\) and \(\mathcal{D}_{\lambda'} : \mathcal{C}'^{\text{op}} \to \mathcal{D}'\). Let \((\alpha, \beta, \gamma)\) be a left representable morphism of pairings from \(\lambda\) to \(\lambda'\). Then the diagram

\[
\begin{array}{ccc}
\mathcal{C}^{\text{op}} & \xrightarrow{\mathcal{D}_\lambda} & \mathcal{D} \\
\downarrow \beta & \downarrow \gamma \\
\mathcal{C}'^{\text{op}} & \xrightarrow{\mathcal{D}_{\lambda'}} & \mathcal{D}'
\end{array}
\]

commutes up to canonical homotopy.

Proof. The right fibrations \(\lambda\) and \(\lambda'\) are classified by functors

\[
\mathcal{C}^{\text{op}} \times \mathcal{D}^{\text{op}} \to \mathcal{S} \quad \mathcal{C}'^{\text{op}} \times \mathcal{D}'^{\text{op}} \to \mathcal{S},
\]

which we can identify with maps \(\chi : \mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{D}^{\text{op}}, \mathcal{S})\) and \(\chi' : \mathcal{C}'^{\text{op}} \to \text{Fun}(\mathcal{D}'^{\text{op}}, \mathcal{S})\). Let

\[
G : \text{Fun}(\mathcal{D}'^{\text{op}}, \mathcal{S}) \to \text{Fun}(\mathcal{C}'^{\text{op}}, \mathcal{S})
\]

be the functor given by composition with \(\beta\). Then \(\alpha\) induces a natural transformation \(\chi \to G \circ \chi' \circ \beta\). Let \(F\) denote a left adjoint to \(G\), so that we obtain a natural transformation \(u : F \circ \chi \to \chi' \circ \beta\) of functors from \(\mathcal{C}^{\text{op}}\) to \(\text{Fun}(\mathcal{D}'^{\text{op}}, \mathcal{S})\). Let \(j_D : \mathcal{D} \to \text{Fun}(\mathcal{D}^{\text{op}}, \mathcal{S})\) and \(j_{D'} : \mathcal{D}' \to \text{Fun}(\mathcal{D}'^{\text{op}}, \mathcal{S})\) denote the Yoneda embeddings.
Then \( \chi \simeq j_D \circ \Omega_\lambda \) and \( \chi' \simeq j_{D'} \circ \Omega_{\lambda'} \), and Proposition T.5.2.6.3 gives an equivalence \( F \circ j_D \simeq j_{D'} \circ \gamma \). Then \( u \) determines a natural transformation
\[
j_{D'} \circ \gamma \circ \Omega_\lambda \simeq F \circ j_D \circ \Omega_\lambda \simeq F \circ \chi \Rightarrow \chi' \circ \beta \simeq j_{D'} \circ \Omega_{\lambda'} \circ \beta.
\]
Since \( j_{D'} \) is fully faithful, this is the image of the a natural transformation of functors \( \gamma \circ \Omega_\lambda \rightarrow \Omega_{\lambda'} \circ \beta \). Our assumption that \( \alpha \) carries left universal objects of \( \mathcal{M} \) to left universal objects of \( \mathcal{M}' \) implies that this natural transformation is an equivalence.

In what follows, we will focus our attention on right representable pairings of \( \infty \)-categories (though all of our results are have analogues for left representable pairings, which can be proven in the same way).

**Proposition 5.2.1.18.** Let \( \mathcal{C} \) be an \( \infty \)-category and let \( \lambda : \text{TwArr}(\mathcal{C}) \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}} \) be the pairing of Proposition 5.2.1.3. Let \( \mu : \mathcal{M} \rightarrow \mathcal{D} \times \mathcal{E} \) be an arbitrary right representable pairing of \( \infty \)-categories. Then the evident maps
\[
\text{Map}_{\text{CPair}}(\lambda, \mu) \rightarrow \text{Map}_{\text{Cat}_\infty}(\mathcal{C}\text{op}, \mathcal{E}) \quad \text{Map}_{\text{CPair}}(\mu, \lambda) \rightarrow \text{Map}_{\text{Cat}_\infty}(\mathcal{D}, \mathcal{C})
\]
are homotopy equivalences.

Before giving the proof of Proposition 5.2.1.18, let us describe some of its consequences.

**Corollary 5.2.1.19.** Let \( \phi, \psi : \text{CPair}^R \rightarrow \text{Cat}_\infty \) be the forgetful functors given on objects by the formulas
\[
\phi(\lambda : \mathcal{M} \rightarrow \mathcal{C} \times \mathcal{D}) = \mathcal{C} \quad \psi(\lambda : \mathcal{M} \rightarrow \mathcal{C} \times \mathcal{D}) = \mathcal{D}.
\]
Then:

1. The functor \( \phi \) admits a right adjoint, given at the level of objects by \( \mathcal{C} \mapsto \text{TwArr}(\mathcal{C}) \).
2. The functor \( \psi \) admits a left adjoint, given at the level of objects by \( \mathcal{D} \mapsto \text{TwArr}(\mathcal{D}^{\text{op}}) \).

*Proof.* Combine Propositions 5.2.1.18 and T.5.2.4.2.

**Remark 5.2.1.20.** Let us say that a pairing of \( \infty \)-categories is **perfect** if it is equivalent (in the \( \infty \)-category \( \text{CPair} \)) to a pairing of the form \( \text{TwArr}(\mathcal{C}) \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}} \), for some \( \infty \)-category \( \mathcal{C} \). We let \( \text{CPair}^{\text{perf}} \) denote the subcategory of \( \text{CPair} \) whose objects are perfect pairings of \( \infty \)-categories and whose morphisms are right representable morphisms of pairings (note that if \( \lambda \) and \( \lambda' \) are perfect pairings of \( \infty \)-categories, then Proposition 5.2.1.10 implies that a morphism of pairings from \( \lambda \) to \( \lambda' \) is left representable if and only if it is right representable). It follows from Corollary 5.2.1.19 that the full subcategory \( \text{CPair}^{\text{perf}} \subseteq \text{CPair}^R \) is both a localization and a colocalization of \( \text{CPair}^R \). Moreover, the forgetful functors \( \phi, \psi : \text{CPair}^R \rightarrow \text{Cat}_\infty \) of Corollary 5.2.1.19 restrict to equivalences \( \text{CPair}^{\text{perf}} \rightarrow \text{Cat}_\infty \). Composing these equivalences, we obtain an equivalence of \( \infty \)-categories from \( \text{Cat}_\infty \) to itself, given at the level of objects by \( \mathcal{C} \mapsto \mathcal{C}^{\text{op}} \).

**Remark 5.2.1.21.** Let \( \mu : \mathcal{M} \rightarrow \mathcal{C} \times \mathcal{D} \) be a right representable pairing of \( \infty \)-categories, and let \( \lambda : \text{TwArr}(\mathcal{C}) \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}} \) be the pairing of Proposition 5.2.1.3. Using Proposition 5.2.1.18, we can lift the identity functor \( \text{id} \) to a right representable morphism of pairings \( (\alpha, \beta, \gamma) : \mu \rightarrow \lambda \). For every object \( \mathcal{D} \in \mathcal{D} \), the induced map
\[
\gamma_D : \mathcal{M} \times \mathcal{D} \{D\} \rightarrow \text{TwArr}(\mathcal{C}) \times C^{\text{op}} \{\beta(D)\}
\]
is a map between representable right fibrations over \( \mathcal{C} \) which preserves final objects, and therefore an equivalence of \( \infty \)-categories. It follows that the diagram
\[
\begin{array}{ccc}
\mathcal{M} & \xrightarrow{\gamma} & \text{TwArr}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\mathcal{D} & \xrightarrow{\beta} & \mathcal{C}^{\text{op}}
\end{array}
\]
is homotopy Cartesian (note that the vertical maps are Cartesian fibrations, so that this condition can be tested fiberwise).
Corollary 5.2.1.22. Let $\mu : M \to C \times D$ be a pairing of $\infty$-categories. The following conditions are equivalent:

1. The pairing $\mu$ is perfect.
2. The pairing $\mu$ is both left and right representable, and an object of $M$ is left universal if and only if it is right universal.
3. The pairing $\mu$ is both left and right representable, and the adjoint functors
   
   $D^{\text{op}} \mu : C \to D^{\text{op}}$ and $D^{\text{op}} \mu : D^{\text{op}} \to C$

   of Construction 5.2.1.9 are mutually inverse equivalences.

Proof. We first prove that conditions (2) and (3) are equivalent. Assume that $\mu$ is both left and right representable. Let $C \in C$, and choose a left universal object $M \in M$ lying over $C$. Let $D = D_{\mu}(C)$ be the image of $M$ in $D$, and choose a right universal object $N \in M$ lying over $D$. Then $N$ is a final object of $M \times_D \{D\}$, so there is a canonical map $u_0 : M \to N$ in $M$. Unwinding the definitions, we see that the image of $u_0$ in $C$ can be identified with the unit map $u : C \to D^{\text{op}} \mu(D)$. Since $\mu$ is a right fibration and the image of $u_0$ in $D$ is an equivalence, we conclude that $u$ is an equivalence if and only if $u_0$ is an equivalence. That is, $u$ is an equivalence if and only if $M$ is also a right universal object of $M$. This proves the following:

(*) The unit map $\text{id}_C \to D^{\text{op}} \mu \circ D^{\text{op}} \mu$ is an equivalence if and only if every left universal object of $M$ is also right universal.

The same argument proves:

(′) The counit map $D^{\text{op}} \mu \circ D^{\text{op}} \mu \to \text{id}_{D^{\text{op}}}$ is an equivalence if and only if every right universal object of $M$ is also left universal.

Combining (·) and (′), we deduce that conditions (2) and (3) are equivalent.

The implication (1) $\Rightarrow$ (2) follows from Proposition 5.2.1.10. We will complete the proof by showing that (3) $\Rightarrow$ (1). Let $\lambda : \text{TwArr}(C) \to C \times C^{\text{op}}$ be the pairing of Proposition 5.2.1.3. Since $\lambda$ is right representable, the identity functor $\text{id}_C$ can be lifted to a right representable morphism of pairings $(\text{id}_C, \beta, \gamma) : \mu \to \lambda$. We wish to prove that $\beta$ and $\gamma$ are equivalences. Since the diagram

$$
\begin{array}{ccc}
M & \xrightarrow{\gamma} & \text{TwArr}(C) \\
\downarrow & & \downarrow \\
D & \xrightarrow{\beta} & C^{\text{op}}
\end{array}
$$

is homotopy Cartesian (Remark 5.2.1.21), it will suffice to show that $\beta$ is an equivalence of $\infty$-categories.

Using Proposition 5.2.1.17, we see that the diagram of $\infty$-categories

$$
\begin{array}{ccc}
D^{\text{op}} & \xrightarrow{D^{\text{op}} \lambda} & C \\
\downarrow & & \downarrow \text{id} \\
C & \xrightarrow{\text{id}} & C
\end{array}
$$

commutes up to homotopy: that is, $\beta$ is homotopic to $D^{\text{op}} \lambda$, and is therefore an equivalence by virtue of assumption (3).

We now turn to the proof of Proposition 5.2.1.18. We begin with a general discussion of the mapping spaces in the $\infty$-category $C\text{Pair}$. Suppose we are given pairings of $\infty$-categories

$$
\lambda : M \to C \times D \quad \lambda' : M' \to C' \times D'.
$$
We have an evident map of simplicial sets

\[ \theta : \text{Map}_{\text{CPair}}(\lambda, \lambda') \to \text{Fun}(\mathcal{C}, \mathcal{C}')^\simeq \times \text{Fun}(\mathcal{D}, \mathcal{D}')^\simeq. \]

**Lemma 5.2.1.23.** In the situation described above, the map \( \theta \) is a Kan fibration. In particular, the mapping space \( \text{Map}_{\text{CPair}}(\lambda, \lambda') \) is a Kan complex.

**Proof.** Since \( \text{Fun}(\mathcal{C}, \mathcal{C}')^\simeq \times \text{Fun}(\mathcal{D}, \mathcal{D}')^\simeq \) is a Kan complex, it will suffice to show that the map \( \theta \) is a right fibration (Lemma T.2.1.3.3). We will prove that \( \theta \) has the right lifting property with respect to every right anodyne map of simplicial sets \( i : A \to B \). Fix a map \( B \to \text{Fun}(\mathcal{C}, \mathcal{C}')^\simeq \times \text{Fun}(\mathcal{D}, \mathcal{D}')^\simeq \), and let \( N \) denote the fiber product \( (\mathcal{C} \times \mathcal{D} \times B) \times_{\mathcal{C}' \times \mathcal{D}'} M' \). Unwinding the definitions, we are reduced to solving a lifting problem of the form

\[
\begin{array}{ccc}
A \times M & \to & N \\
\downarrow & & \downarrow \\
B \times M & \to & \mathcal{C} \times \mathcal{D}.
\end{array}
\]

The desired result now follows from the fact that \( i' \) is right anodyne (Corollary T.2.1.2.7), since \( \lambda' \) is a right fibration. \( \square \)

Our next step is to analyze the fibers of Kan fibration \( \theta : \text{Map}_{\text{CPair}}(\lambda, \lambda') \to \text{Fun}(\mathcal{C}, \mathcal{C}')^\simeq \times \text{Fun}(\mathcal{D}, \mathcal{D}')^\simeq \). Fix a pair of functors \( \alpha : \mathcal{C} \to \mathcal{C}' \) and \( \beta : \mathcal{D} \to \mathcal{D}' \). Unwinding the definitions, we see that the fiber \( \theta^{-1}\{(\alpha, \beta)\} \) is the \( \infty \)-category \( \text{Fun}_{\mathcal{C}' \times \mathcal{D}'}(M, M') \). Let \( \chi : \mathcal{C}'^{\text{op}} \times \mathcal{D}'^{\text{op}} \to \mathcal{S} \) classify the right fibration \( \lambda \), and let \( \chi' : \mathcal{C}'^{\text{op}} \times \mathcal{D}'^{\text{op}} \to \mathcal{S} \) classify the right fibration \( \lambda' \). Then \( \text{Fun}_{\mathcal{C}' \times \mathcal{D}'}(M, M') \) is homotopy equivalent to the mapping space \( \text{Map}_{\text{Fun}(\mathcal{C}'^{\text{op}} \times \mathcal{D}'^{\text{op}}, \mathcal{S})}(\chi, \chi' \circ (\alpha \times \beta)) \). Let \( \mathcal{P}(\mathcal{C}) = \text{Fun}(\mathcal{C}'^{\text{op}}, \mathcal{S}) \) and define \( \mathcal{P}(\mathcal{C}') \) similarly, so that \( \chi \) and \( \chi' \) can be identified with maps \( \nu : \mathcal{D}'^{\text{op}} \to \mathcal{P}(\mathcal{C}) \) and \( \nu' : \mathcal{D}'^{\text{op}} \to \mathcal{P}(\mathcal{C}') \). We then have

\[
\text{Map}_{\text{Fun}(\mathcal{C}'^{\text{op}} \times \mathcal{D}'^{\text{op}}, \mathcal{S})}(\chi, \chi' \circ (\alpha \times \beta)) \simeq \text{Map}_{\text{Fun}(\mathcal{D}'^{\text{op}}, \mathcal{P}(\mathcal{C}))(\nu \circ \nu' \circ \beta)},
\]

where \( G : \mathcal{P}(\mathcal{C}') \to \mathcal{P}(\mathcal{C}) \) is the map given by composition with \( \alpha \). Note that \( G \) admits a left adjoint \( \pi : \mathcal{P}(\mathcal{C}) \to \mathcal{P}(\mathcal{C}') \), which fits into a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C} & \to & \mathcal{P}(\mathcal{C}) \\
\downarrow & \downarrow \pi & \downarrow \alpha \\
\mathcal{D} & \to & \mathcal{P}(\mathcal{D}),
\end{array}
\]

where the horizontal maps are given by the Yoneda embeddings (see Proposition T.5.2.6.3). Combining this observation with the analysis above, we obtain a homotopy equivalence

\[
\theta^{-1}\{(\alpha, \beta)\} = \text{Map}_{\text{Fun}(\mathcal{D}'^{\text{op}}, \mathcal{P}(\mathcal{C}))(\pi \circ \nu \circ \nu' \circ \beta)}.
\]

Let us now specialize to the case where the pairings \( \lambda : M \to \mathcal{C} \times \mathcal{D} \) and \( \lambda' : M' \to \mathcal{C}' \times \mathcal{D}' \) are right representable. In this case, the functors \( \nu \) and \( \nu' \) admit factorizations

\[
\mathcal{D}^{\text{op}} \xrightarrow{\mathcal{D}_\lambda} \mathcal{C} \to \mathcal{P}(\mathcal{C})
\]

\[
\mathcal{D}'^{\text{op}} \xrightarrow{\mathcal{D}'_\lambda} \mathcal{C}' \to \mathcal{P}(\mathcal{C}')
\]

(see Construction 5.2.1.9). We may therefore identify \( \theta^{-1}\{(\alpha, \beta)\} \) with the mapping space

\[
\text{Map}_{\text{Fun}(\mathcal{D}'^{\text{op}}, \mathcal{P}(\mathcal{C}))(\lambda \circ \mathcal{D}_\lambda, \mathcal{D}'_\lambda' \circ \beta)}.
\]
Under this identification, the subspace
\[ \text{Map}_{\text{CPair}^n}(\lambda, \lambda') \times \text{Fun}(\mathcal{C}, \mathcal{C}') \times \text{Fun}(\mathcal{D}, \mathcal{D}') = \{ (\alpha, \beta) \} \]
corresponds to the summand of \( \text{Map}_{\text{Fun}(\mathcal{D}, \mathcal{D}')} \alpha \circ \mathcal{D}' \lambda \circ \beta \) spanned by the equivalences \( \alpha \circ \mathcal{D}' \lambda \simeq \mathcal{D}' \lambda \circ \beta \) (see Proposition 5.2.1.17 and its proof).

**Proof of Proposition 5.2.1.18.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( \lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}} \) be the pairing of Proposition 5.2.1.3, and let \( \mu : \mathcal{M} \to \mathcal{D} \times \mathcal{E} \) be an arbitrary right representable pairing of \( \infty \)-categories. We first show that the forgetful functor
\[ \text{Map}_{\text{CPair}^n}(\lambda, \mu) \to \text{Map}_{\text{Cat}_\infty}(\mathcal{C}^{\text{op}}, \mathcal{E}) \]
is a homotopy equivalence. Let \( \text{Map}_{\text{CPair}^n}(\lambda, \mu) \) denote the full simplicial subset of \( \text{Map}_{\text{CPair}^n}(\lambda, \mu) \) spanned by the right representable morphisms of pairings. It follows from Lemma 5.2.1.23 that the map of simplicial sets
\[ \phi : \text{Map}_{\text{CPair}^n}(\lambda, \mu) \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{E})^\simeq \]
is a Kan fibration. It will therefore suffice to show that the fibers of \( \phi \) are contractible. Fix a functor \( \beta : \mathcal{C}^{\text{op}} \to \mathcal{E} \), so that we have a Kan fibration of simplicial sets \( u : \phi^{-1}\{\beta\} \to \text{Fun}(\mathcal{C}, \mathcal{D})^\simeq \). Combining Remark 5.2.1.12 with the analysis given above, we see that the fiber of \( u \) over a functor \( \alpha : \mathcal{C} \to \mathcal{D} \) can be identified with the summand of \( \text{Map}_{\text{Fun}(\mathcal{D}, \mathcal{E})}(\alpha, \mathcal{D}' \circ \beta) \) spanned by the equivalences. It follows that \( u \) is a right fibration represented by the object \( \mathcal{D}' \circ \beta \in \text{Fun}(\mathcal{C}, \mathcal{D}) \), so that the fiber \( \phi^{-1}\{\beta\} \) is equivalent to \( \text{Fun}(\mathcal{C}, \mathcal{D})^\simeq_{/\mathcal{D}' \circ \beta} \) and therefore contractible.

We now show that the forgetful functor \( \text{Map}_{\text{CPair}^n}(\mu, \lambda) \to \text{Map}_{\text{Cat}_\infty}(\mathcal{D}, \mathcal{E}) \) is a homotopy equivalence. For this, it suffices to show that the Kan fibration of simplicial sets \( \psi : \text{Map}_{\text{CPair}^n}(\mu, \lambda) \to \text{Fun}(\mathcal{D}, \mathcal{E})^\simeq \) has contractible fibers. Fix a functor \( \alpha : \mathcal{D} \to \mathcal{C} \), so that we have a Kan fibration \( v : \psi^{-1}\{\alpha\} \to \text{Fun}(\mathcal{E}, \mathcal{C}^{\text{op}})^\simeq \). Using Remark 5.2.1.12 and the above analysis, we see that the fiber of \( v \) over a map \( \beta : \mathcal{E} \to \mathcal{C}^{\text{op}} \) can be identified with the summand of the mapping space \( \text{Map}_{\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{E})}(\alpha \circ \mathcal{D}' \mu, \beta) \). It follows that \( v \) is a left fibration represented by the object \( \alpha \circ \mathcal{D}' \mu \in \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{C}) \), so that the fiber \( \psi^{-1}\{\alpha\} \) is equivalent to \( \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{C})^\simeq_{\mathcal{D}' \circ \alpha} \) and therefore contractible. \( \square \)

We conclude this section by introducing a relative version of the twisted arrow construction which will be needed in §5.2.3.

**Construction 5.2.1.24.** Let \( \lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D} \), be a pairing of \( \infty \)-categories, classified by a functor \( \chi : \mathcal{D}^{\text{op}} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) = \mathcal{P}(\mathcal{C}) \). Let \( j : \mathcal{C} \to \mathcal{P}(\mathcal{C}) \) be the Yoneda embedding, and set
\[ \mathcal{C}_\lambda = \mathcal{C} \times \text{Fun}(\mathcal{M}(0), \mathcal{C}^{\text{op}}, \mathcal{S}) \times \text{Fun}(\mathcal{M}(1), \mathcal{C}^{\text{op}}, \mathcal{S}) curly \mathcal{D}^{\text{op}}. \]

Let \( e_0 : \mathcal{C}_\lambda \to \mathcal{C} \) and \( e_1 : \mathcal{C}_\lambda \to \mathcal{D}^{\text{op}} \) be the two projection maps, so that we have a natural transformation \( \alpha : (j \circ e_0) \to (\chi \circ e_1) \) of functors \( \mathcal{C}_\lambda \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \). The functor \( j \circ e_0 \) classifies a right fibration \( \mu : \text{TwArr}_\chi(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}_\lambda^{\text{op}} \), which we regard as a pairing of \( \infty \)-categories. We will refer to \( \text{TwArr}_\chi(\mathcal{C}) \) as the \( \infty \)-category of twisted arrows of \( \mathcal{C} \) relative to \( \lambda \).

Note that \( \alpha \) classifies a map \( \gamma : \text{TwArr}_\chi(\mathcal{C}) \to \mathcal{M} \times \mathcal{D} \times \mathcal{C}_\lambda^{\text{op}} \) of right fibrations over \( \mathcal{C} \times \mathcal{C}_\lambda^{\text{op}} \). We therefore obtain a morphism of pairings
\[ \begin{array}{ccc} \text{TwArr}_\chi(\mathcal{C}) & \xrightarrow{\gamma} & \mathcal{M} \\ \mu \downarrow & & \downarrow \lambda \\ \mathcal{C} \times \mathcal{C}_\lambda^{\text{op}} & \xrightarrow{id \times e_1} & \mathcal{C} \times \mathcal{D}. \end{array} \]
Example 5.2.1.25. In the setting of Construction 5.2.1.24, suppose that $\mathcal{D} = \Delta^0$ and that $\lambda$ is the identity map from $\mathcal{C}$ to itself. In this case, the evaluation map $e_0 : \mathcal{E}_\lambda \to \mathcal{C}$ is an equivalence, and the right fibration $\text{TwArr}_\lambda(\mathcal{C}) \to \mathcal{C} \times \mathcal{E}_\lambda^{\text{op}}$ classifies the Yoneda pairing

$$\mathcal{E}^{\text{op}} \times \mathcal{E}_\lambda \simeq \mathcal{C} \times \mathcal{C} \to S.$$ 

Applying Proposition 5.2.1.11, we deduce that the pairing $\text{TwArr}_\lambda(\mathcal{C}) \to \mathcal{C} \times \mathcal{E}_\lambda^{\text{op}}$ is equivalent to the pairing $\text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{E}_\lambda^{\text{op}}$ of Construction 5.2.1.24 (this can also be deduced by comparing the universal properties of $\text{TwArr}(\mathcal{C})$ and $\text{TwArr}_\lambda(\mathcal{C})$ given by Proposition 5.2.1.18 and 5.2.1.26, respectively).

Proposition 5.2.1.26. Let $\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ be a pairing of $\infty$-categories, let $\mu : \text{TwArr}_\lambda(\mathcal{C}) \to \mathcal{C} \times \mathcal{E}_\lambda^{\text{op}}$ be as in Construction 5.2.1.24. Then:

1. The pairing $\mu$ is right representable.
2. Let $\lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}'$ be an arbitrary right representable pairing of $\infty$-categories. Then composition with the canonical morphism $\mu \to \lambda$ induces a homotopy equivalence

$$\theta : \text{Map}_{\text{CPair}}(\lambda', \mu) \to \text{Map}_{\text{CPair}}(\lambda, \mu).$$

Corollary 5.2.1.27. The inclusion functor $\text{CPair}^R \to \text{CPair}$ admits a right adjoint, given on objects by the construction

$$(\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}) \mapsto (\text{TwArr}_\lambda(\mathcal{C}) \to \mathcal{C} \times \mathcal{E}_\lambda^{\text{op}}).$$

Proof of Proposition 5.2.1.26. We have a commutative diagram

$$\text{Map}_{\text{CPair}}(\lambda', \mu) \xrightarrow{q} \text{Map}_{\text{CPair}}(\lambda', \lambda) \xrightarrow{p} \text{Map}_{\text{CPair}}(\lambda, \lambda) \xrightarrow{\theta} \text{Map}_{\text{CPair}}(\lambda, \lambda).$$

To prove that $\theta$ is a homotopy equivalence, it will suffice to show that $\theta$ induces a homotopy equivalence of homotopy fibers over any pair of functors $(F : \mathcal{C} \to \mathcal{C}', G : \mathcal{D} \to \mathcal{D}')$. It now suffice to observe that both homotopy fibers can be identified with the mapping space $\text{Map}_{\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{D}^{\text{op}})}(\lambda', \lambda \circ (F \times G))$, where $\lambda$ and $\lambda'$ classify the right fibrations $\lambda$ and $\lambda'$, respectively.

Remark 5.2.1.28. Let $\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ be a pairing of $\infty$-categories and let $\mu : \text{TwArr}_\lambda(\mathcal{C}) \to \mathcal{C} \times \mathcal{E}_\lambda^{\text{op}}$ be the pairing of Construction 5.2.1.24. Assume that $\lambda$ is left representable, so that the duality functor $\mathcal{D}_\lambda : \mathcal{E}^{\text{op}} \to \mathcal{D}$ is defined. Unwinding the definitions, we see that $\mathcal{E}^{\text{op}}_{\lambda}$ is equivalent to the $\infty$-category $\mathcal{E}^{\text{op}} \times_{\mathcal{D}} \text{Fun}(\Delta^1, \mathcal{D})$ whose objects are triples $(C, D, \phi)$ where $C \in \mathcal{E}^{\text{op}}$, $D \in \mathcal{D}$, and $\phi : D \to \mathcal{D}_\lambda(C)$ is a morphism in $\mathcal{D}$. In particular, the forgetful functor $\mathcal{E}^{\text{op}}_{\lambda} \to \mathcal{E}^{\text{op}}$ admits a fully faithful left adjoint $L$, whose essential image is spanned by those triples $(C, D, \phi)$ where $\phi : D \to \mathcal{D}_\lambda(C)$ is an equivalence in $\mathcal{D}$. We will denote this essential image by $\mathcal{E}^{\text{op}}_{\lambda}^L$, and we let $\text{TwArr}_{\lambda}(\mathcal{C})$ denote the inverse image of $\mathcal{C} \times (\mathcal{E}^{\text{op}}_{\lambda}^L)$ in $\text{TwArr}_\lambda(\mathcal{C})$.

Remark 5.2.1.29. Suppose we are given a morphism of pairings

$$\mathcal{M} \longrightarrow \mathcal{M}' \quad \lambda \quad \mathcal{C} \times \mathcal{D} \longrightarrow \mathcal{E} \times \mathcal{D}'$$
We then obtain an induced right representable morphism of pairings

\[ \text{TwArr}_\lambda(\mathcal{C}) \rightarrow \text{TwArr}(\mathcal{C}) \]

\[ \mathcal{C} \times \mathcal{C}^{\text{op}} \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}}. \]

Taking \( D' = \Delta^0 \) and \( M' = \mathcal{C} \), we obtain a morphism of pairings

\[ \text{TwArr}_\lambda(\mathcal{C}) \rightarrow \text{TwArr}(\mathcal{C}) \]

\[ \mathcal{C} \times \mathcal{C}^{\text{op}} \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}}. \]

(see Example 5.2.1.25). If \( \lambda \) is left representable, this morphism restricts to an equivalence

\[ \text{TwArr}_\lambda^0(\mathcal{C}) \rightarrow \text{TwArr}(\mathcal{C}) \]

\[ \mathcal{C} \times (\mathcal{C}^0)^{\text{op}} \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}}, \]

where the pairing on the left is defined as in Remark 5.2.1.28.

### 5.2.2 The Bar Construction for Associative Algebras

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category with unit object \( 1 \). Let \( A \) be an associative algebra object of \( \mathcal{C} \). An augmentation on \( A \) is a map of associative algebra objects \( \epsilon : A \rightarrow 1 \). In this case, we will refer to \( A \) as an augmented algebra object of \( \mathcal{C} \). We let \( \text{Alg}^{\text{aug}}(\mathcal{C}) \) denote the \( \infty \)-category \( \text{Alg}(\mathcal{C})/1 \) of augmented algebra objects of \( \mathcal{C} \). Note that any augmentation on \( A \) determines a forgetful functor

\[ \rho : \mathcal{C} \rightarrow \mathcal{C} \mathcal{BMod} \rightarrow \mathcal{A} \mathcal{BMod} \]

\[ A \mathcal{BMod}(\mathcal{C}). \]

**Definition 5.2.2.1.** Let \( A \) be an augmented algebra object of a monoidal \( \infty \)-category \( \mathcal{C} \). We will say that a morphism \( f : A \rightarrow \rho(C) \) in \( A \mathcal{BMod}(\mathcal{C}) \) exhibits \( C \) as the bar construction on \( A \) if, for every object \( D \in \mathcal{C} \), composition with \( f \) induces a homotopy equivalence

\[ \text{Map}_{\mathcal{C}}(C, D) \rightarrow \text{Map}_{A \mathcal{BMod}(\mathcal{C})}(A, \rho(D)). \]

**Remark 5.2.2.2.** Let \( A \) be an augmented algebra object of a monoidal \( \infty \)-category \( \mathcal{C} \). If there exists a morphism \( f : A \rightarrow \rho(C) \) in \( A \mathcal{BMod}(\mathcal{C}) \) which exhibits \( C \) as a bar construction on \( A \), then the object \( C \) is uniquely determined up to equivalence. In this case, we will denote the object \( C \) by \( \text{Bar}(A) \).

**Example 5.2.2.3.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits geometric realizations of simplicial objects and assume that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C} \) admits geometric realizations of simplicial objects. If \( A \) is an augmented associative algebra object of \( \mathcal{C} \), then the forgetful functor \( 1 \mathcal{BMod}(\mathcal{C}) \rightarrow A \mathcal{BMod}(\mathcal{C}) \) admits a left adjoint, given by the construction \( M \mapsto [1 \otimes_A M \otimes_A 1 \otimes_A 1 \) (see Proposition 4.6.2.17). Specializing to the case \( M = A \), we deduce that the object \( \text{Bar}(A) \) exists and is given by the formula

\[ \text{Bar}(A) \simeq 1 \otimes_A A \otimes_A 1 \simeq 1 \otimes_A 1. \]
Example 5.2.2.4. Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits small colimits. Then we may regard \( \mathcal{C} \) as endowed with the coCartesian symmetric monoidal structure (see \S 2.4.3). Then the tensor product

\[
\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}
\]

\[
(C, D) \mapsto C \amalg D
\]

preserves sifted colimits. Note that the forgetful functor \( \text{CAlg}(\mathcal{C}) \to \mathcal{C} \) is an equivalence of \( \infty \)-categories (Proposition 2.4.3.9). In particular, every object \( C \in \mathcal{C} \) can be regarded as a commutative algebra object of \( \mathcal{C} \) in an essentially unique way. It follows from Proposition 3.2.4.7 that the relative tensor product \( C \otimes_D E \) can be identified with the pushout of \( C \) with \( E \) over \( D \) in the \( \infty \)-category \( \text{CAlg}(\mathcal{C}) \), and therefore in the \( \infty \)-category \( \mathcal{C} \). In particular, for every \( A \in \mathcal{C} \simeq \text{CAlg}(\mathcal{C}) \), the bar construction \( \text{Bar}(A) = 1 \otimes_A 1 \) can be identified with the suspension \( \Sigma(A) \in \mathcal{C} \).

We will need the following slight generalization of Example 5.2.2.3:

Proposition 5.2.2.5. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits geometric realizations of simplicial objects. Then for every augmented associative algebra object \( A \) of \( \mathcal{C} \), there exists an object \( C \in \mathcal{C} \) and a morphism \( A \to \rho(C) \) in \( \text{AMod}_A(\mathcal{C}) \) which exhibits \( C \) as a bar construction on \( A \).

The proof of Proposition 5.2.2.5 is based on the following simple lemma:

Lemma 5.2.2.6. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category and let \( A \) be an associative algebra object of \( \mathcal{C} \). Then there exists a simplicial object \( X_\bullet \) in \( \text{AMod}_A(\mathcal{C}) \) with the following properties:

(a) The geometric realization of \( X_\bullet \) exists and is equivalent to \( A \) (as an object of \( \text{AMod}_A(\mathcal{C}) \)).

(b) For every integer \( n \geq 0 \), the object \( X_n \in \text{AMod}_A(\mathcal{C}) \) is equivalent to a free bimodule \( A \otimes Y_n \otimes A \), where \( Y_n = A \otimes^n \).

Proof. Suppose first that \( \mathcal{C} \) admits geometric realizations of simplicial objects and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects. In this case, the desired result follows the equivalence \( A \simeq A \otimes_A A \) (Proposition 4.4.3.16), together with the explicit description of \( A \otimes_A A \) supplied by Construction 4.4.2.7.

To treat the general case, it suffices to choose a fully faithful embedding of monoidal \( \infty \)-categories \( f : \mathcal{C} \hookrightarrow \mathcal{C}' \) where \( \mathcal{C}' \) admits geometric realizations and the tensor product \( \otimes : \mathcal{C}' \times \mathcal{C}' \to \mathcal{C}' \) preserves geometric realizations. The first part of the proof shows that \( A \) is given by the geometric realization of a simplicial object \( X_\bullet \) of \( f(A) \text{AMod}_{f(A)}(\mathcal{C}') \) satisfying conditions (a) and (b), and condition (b) implies that each \( X_n \) belongs to the essential image of the induced embedding \( \text{AMod}_A(\mathcal{C}) \to f(A) \text{AMod}_{f(A)}(\mathcal{C}') \). To prove the existence of \( f \), we may assume without loss of generality that \( \mathcal{C} \) is small (enlarging the universe if necessary); in this case, we can take \( \mathcal{C}' = \mathcal{P}(\mathcal{C}) \) and \( f \) to be the Yoneda embedding (see Variant 4.8.1.11). \( \square \)

Remark 5.2.2.7. More informally, Lemma 5.2.2.6 asserts that any associative algebra \( A \) can be recovered as the geometric realization of a simplicial object

\[
\cdots \Rightarrow A \otimes A \otimes A \otimes A \Rightarrow A \otimes A \otimes A \Rightarrow A \otimes A.
\]

The proof supplies a more explicit description of this simplicial object: the face maps are given by the multiplication on \( A \), and the degeneracy maps are given by the unit of \( A \).

Proof of Proposition 5.2.2.5. Let us say that an object \( M \in \text{AMod}_A(\mathcal{C}) \) is good if the functor \( C \mapsto \text{Map}_{\text{AMod}_A(\mathcal{C})}(M, \rho(C)) \) is corepresentable by an object of \( \mathcal{C} \). It follows immediately from the definitions that every free bimodule \( M = A \otimes M_0 \otimes A \) is good (the corresponding functor is corepresented by the object \( M_0 \in \mathcal{C} \)). Since the \( \infty \)-category \( \mathcal{C} \) admits geometric realizations of simplicial objects, the collection of corepresentable functors \( \mathcal{C} \to \mathcal{S} \) is closed under totalizations of cosimplicial objects. It follows that the collection of good objects of \( \text{AMod}_A(\mathcal{C}) \) is closed under geometric realizations of simplicial objects. Using Lemma 5.2.2.6, we deduce that \( A \in \text{AMod}_A(\mathcal{C}) \) is good, as desired. \( \square \)
Remark 5.2.2.8. The proof of Proposition 5.2.2.5 shows that the object \( \text{Bar}(A) \in \mathcal{C} \) is given by the geometric realization of a simplicial object

\[
\cdots \xrightarrow{m} A \otimes A \xrightarrow{c} A \rightarrow 1.
\]

This coincides with the two-sided bar construction \( \text{Bar}_{A}(1,1) \) of Construction 4.4.2.7.

Remark 5.2.2.9. In the situation of Proposition 5.2.2.5, one can show that all objects of \( _A \text{BMod}_A(\mathcal{C}) \) are good, so that the forgetful functor

\[
\mathcal{C} \simeq _1 \text{BMod}_1(\mathcal{C}) \rightarrow _A \text{BMod}_A(\mathcal{C})
\]

admits a left adjoint; see Corollary 5.2.2.39. However, our proof of Corollary 5.2.2.39 does not provide quite so concrete a description of the bar construction \( \text{Bar}(A) \) as the one given in Remark 5.2.2.8.

There is a generalization of Example 5.2.2.4 which describes the structure of the bar construction on a free algebra. First, we need a slight variant on Proposition 4.2.4.10.

Remark 5.2.2.10. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category. Assume that for every countable weakly contractible simplicial set \( K \), the \( \infty \)-category \( \mathcal{C} \) admits \( K \)-indexed colimits and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C} \) preserves \( K \)-indexed colimits separately in each variable. It follows from Corollary 3.1.3.7 that the forgetful functor

\[
\text{Alg}(\mathcal{C}) \rightarrow \text{Alg}_{(\mathcal{C},s)}(\mathcal{C}) \simeq \mathcal{C}_{1/}
\]

admits a left adjoint, which we will denote by \( \text{Fr}_* : \mathcal{C}_{1/} \rightarrow \text{Alg}(\mathcal{C}) \).

Construction 5.2.2.11. Let \( \mathcal{C} \) be as in Remark 5.2.2.10, and suppose we are given an object \( C \in \mathcal{C}_{1/} \) equipped with an augmentation \( \epsilon_0 : C \rightarrow 1 \) (in the \( \infty \)-category \( \mathcal{C}_{1/} \)). Then \( \epsilon_0 \) induces a morphism of algebras \( \epsilon : \text{Fr}_*(C) \rightarrow 1 \) which allows us to regard \( 1 \) as a left \( \text{Fr}_*(C) \)-module and \( \epsilon \) as a morphism of left \( \text{Fr}_*(C) \)-modules. The canonical map \( C \rightarrow \text{Fr}_*(C) \) extends to a map of left \( \text{Fr}_*(C) \)-modules \( m : \text{Fr}_*(C) \otimes C \rightarrow \text{Fr}_*(C) \), and the morphism \( \epsilon_0 \) induces a map of free modules \( \tau_0 : \text{Fr}_*(C) \otimes C \rightarrow \text{Fr}_*(C) \otimes 1 \simeq \text{Fr}_*(C) \). As in the discussion preceding Proposition 4.2.4.10, we see that there is a canonical homotopy from \( \epsilon \circ \tau_0 \) to \( \epsilon \circ m \), which determines a commutative diagram

\[
\begin{array}{ccc}
\text{Fr}_*(C) \otimes C & \xrightarrow{m} & \text{Fr}_*(C) \\
\downarrow{\tau_0} & & \downarrow{\epsilon} \\
\text{Fr}_*(C) & \xrightarrow{\epsilon} & 1
\end{array}
\]

in \( \text{LMod}_{\text{Fr}_*(C)}(\mathcal{C}) \).

Proposition 5.2.2.12. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category. Assume that for every countable weakly contractible simplicial set \( K \), the \( \infty \)-category \( \mathcal{C} \) admits \( K \)-indexed colimits and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C} \) preserves \( K \)-indexed colimits separately in each variable. Then for every object \( C \in \mathcal{C}_{1/} \), the commutative diagram \( \sigma_C \):

\[
\begin{array}{ccc}
\text{Fr}_*(C) \otimes C & \xrightarrow{m} & \text{Fr}_*(C) \\
\downarrow{\tau_0} & & \downarrow{\epsilon} \\
\text{Fr}_*(C) & \xrightarrow{\epsilon} & 1
\end{array}
\]

of Construction 5.2.2.11 is a pushout square in \( \text{LMod}_{\text{Fr}_*(C)}(\mathcal{C}) \).

Proof. Using Corollary 4.2.3.5, we are reduced to proving that the diagram \( \sigma_C \) is a pushout square in the \( \infty \)-category \( \mathcal{C} \). Using the constructions of §4.8.1, we can choose a fully faithful embedding of monoidal \( \infty \)-categories \( u : \mathcal{C} \rightarrow \overline{\mathcal{C}} \) with the following properties:
(i) The \(\infty\)-category \(\mathcal{C}\) admits countable colimits.

(ii) The tensor product on \(\mathcal{C}\) preserves countable colimits.

(iii) The functor \(u\) preserves colimits indexed by countable weakly contractible simplicial sets.

Remark 3.1.3.8 implies that the embedding \(u\) is compatible with the free algebra functor \(\text{Fr}_*\). We may therefore replace \(\mathcal{C}\) by \(\mathcal{C}\) and thereby reduce to the case where the \(\infty\)-category \(\mathcal{C}\) itself satisfies conditions (i) and (ii). In this case, the forgetful functor \(\text{Alg}(\mathcal{C}) \to \mathcal{C}\) admits a left adjoint \(\text{Fr} : \mathcal{C} \to \text{Alg}(\mathcal{C})\), given concretely by the formula \(\text{Fr}(X) = \text{Fr}_*(1 \amalg X)\).

Note that the forgetful functor \(g : \mathcal{C}_{1/1} \to \mathcal{C}_{/1}\) admits a left adjoint \(f\), given by \(f(X) = 1 \amalg X\). The functor \(g\) exhibits \(\mathcal{C}_{1/1}\) as monadic over \(\mathcal{C}_{/1}\) (this is a special case of Theorem 4.7.0.3). Using Proposition 4.7.4.14, we see that \(C\) can be written as the geometric realization of a simplicial object \(C_*\) of \(\mathcal{C}_{1/1}\), where each \(C_n\) belongs to the essential image of \(f\). Since the construction \(C \mapsto \sigma_C\) commutes with the formation of geometric realizations, we can replace \(C\) by \(C_n\) and thereby reduce to the case where \(C = f(C')\) for some \(C' \in \mathcal{C}_{/1}\). In this case, the diagram \(\sigma_C\) can be rewritten as

\[
\begin{array}{ccc}
(\text{Fr}(C') \otimes C') \amalg \text{Fr}(C') & \xrightarrow{\alpha \amalg \text{Id}} & \text{Fr}(C') \\
\downarrow^{\beta \amalg \text{Id}} & & \downarrow \\
\text{Fr}(C') & \xrightarrow{1} & 1.
\end{array}
\]

The assertion that this diagram is a pushout is equivalent to the assertion that it exhibits \(1\) as a coequalizer of the pair of maps \(\alpha, \beta : \text{Fr}(C') \otimes C' \to \text{Fr}(C')\), where \(\alpha\) is induced by the multiplication on \(\text{Fr}(C')\) and \(\beta\) is induced by the augmentation on \(C\). This follows from Proposition 4.2.4.10.

**Corollary 5.2.2.13.** Let \(\mathcal{C}\) be a monoidal \(\infty\)-category. Assume that for every countable weakly contractible simplicial set \(K\), the \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed colimits and that the tensor product \(\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}\) preserves \(K\)-indexed colimits separately in each variable. Then the composite map

\[
\mathcal{C}_{1/1} \xrightarrow{\text{Fr}_*} \text{Alg}^\text{aug}(\mathcal{C}) \xrightarrow{\text{Bar}(\cdot)} \mathcal{C}
\]

is given by \(C \mapsto 1 \amalg C\).

**Proof.** We have canonical equivalences

\[
\text{Bar}(\text{Fr}_*(C)) \simeq 1 \otimes_{\text{Fr}_*(C)} 1 \\
\simeq 1 \otimes_{\text{Fr}_*(C)} (\text{Fr}_*(C) \amalg C \amalg \text{Fr}_*(C)) \\
\simeq 1 \amalg C 1.
\]

**Remark 5.2.2.14.** In the special case where the unit object of \(\mathcal{C}\) is both initial and final (so that \(\mathcal{C}\) is a pointed \(\infty\)-category), we can simplify the statement of Corollary 5.2.2.13: it asserts that if \(C \in \mathcal{C}\) and \(\text{Fr}(C)\) denotes the free associative algebra object of \(\mathcal{C}\) generated by \(C\), then there is a canonical equivalence \(\text{Bar}(\text{Fr}(C)) \simeq \Sigma C\).

**Remark 5.2.2.15.** In the situation of Corollary 5.2.2.13, the identification \(\text{Bar}(\text{Fr}_*(C)) \simeq 1 \amalg C 1\) is given by the composition

\[
1 \amalg C 1 \to 1 \amalg \text{Fr}_*(C) 1 \to 1 \otimes_{\text{Fr}_*(C)} 1.
\]

Our goal in this section is to study some of the properties of the bar construction \(A \mapsto \text{Bar}(A)\). For simplicity, let us first consider the situation of Example 5.2.2.3 (where the bar construction \(\text{Bar}(A)\) is given by the relative tensor product \(1 \otimes_A 1\) defined in §4.4.2). Our main results can be summarized as follows:
Consider the map
\[ \text{Bar}(A) = 1 \otimes_A 1 \]
\[ \simeq 1 \otimes_A A \otimes_A 1 \]
\[ \to 1 \otimes_A 1 \otimes 1 \otimes_A 1 \]
\[ \simeq 1 \otimes_A 1 \otimes 1 = \text{Bar}(A) \otimes \text{Bar}(A). \]

We can view this map as giving a comultiplication \( \delta : \text{Bar}(A) \to \text{Bar}(A) \otimes \text{Bar}(A) \). We will show that this comultiplication is coherently associative: that is, it exhibits \( \text{Bar}(A) \) as an associative algebra object in the monoidal \( \infty \)-category \( \mathcal{C}^{\text{op}} \). Moreover, this algebra object is equipped with a canonical augmentation, given by the morphism
\[ 1 \simeq 1 \otimes 1 \to 1 \otimes_A 1 = \text{Bar}(A) \]
in \( \mathcal{C} \).

The object \( \text{Bar}(A) \in \mathcal{C} \) depends functorially on \( A \) (as an associative algebra object of \( \mathcal{C}^{\text{op}} \)). More precisely, we view the bar construction as providing a functor
\[ \text{Bar} : \text{Alg}^{\text{aug}}(\mathcal{C})^{\text{op}} \to \text{Alg}^{\text{aug}}(\mathcal{C}^{\text{op}}). \]

Assume that \( \mathcal{C} \) admits totalizations of cosimplicial objects. Then \( \mathcal{C}^{\text{op}} \) admits geometric realizations of simplicial objects, so that we can apply the bar construction to augmented associative algebra objects of \( \mathcal{C}^{\text{op}} \). This yields a functor
\[ \text{Cobar} : \text{Alg}^{\text{aug}}(\mathcal{C}^{\text{op}}) \to \text{Alg}^{\text{aug}}(\mathcal{C})^{\text{op}}, \]
which we will refer to as the cobar construction. If \( C \) is an augmented algebra object of \( \mathcal{C}^{\text{op}} \) (which we can think of as a augmented coalgebra object of \( \mathcal{C} \)), then \( \text{Cobar}(C) \) is given by the totalization of a cosimplicial diagram
\[ 1 \longrightarrow C \longrightarrow C \otimes C \longrightarrow \cdots \]
The functor \( \text{Cobar} : \text{Alg}^{\text{aug}}(\mathcal{C}^{\text{op}}) \to \text{Alg}^{\text{aug}}(\mathcal{C})^{\text{op}} \) is adjoint to the bar construction \( \text{Bar} : \text{Alg}^{\text{aug}}(\mathcal{C})^{\text{op}} \to \text{Alg}^{\text{aug}}(\mathcal{C}^{\text{op}}). \)

Warning 5.2.2.16. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits geometric realizations of simplicial objects and totalizations of cosimplicial objects. There are many cases of interest in which the tensor product
\[ \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \]
preserves geometric realizations of simplicial objects or totalizations of cosimplicial objects, but there are relatively few cases in which the tensor product functor has both of these properties. Consequently, if we wish to discuss the bar and cobar constructions on an equal footing, it is important to give arguments which do not require either of these assumptions. This will require us to exercise some additional care: for example, while it is still possible to define relative tensor products \( M \otimes_A N \) (as the geometric realization of a bar construction), it is no longer associative in general. For this reason, we will refrain from analyzing the bar construction \( A \mapsto \text{Bar}(A) \) using the formalism developed in §4.4.2.

To simplify the discussion, it will be convenient to assume that the unit object \( 1 \in \mathcal{C} \) is both initial and final. This can always be achieved by replacing \( \mathcal{C} \) by the \( \infty \)-category \( \mathcal{C}_{1/1} \); we will give a more thorough discussion of this point in §5.2.3. Note that the assumption that \( 1 \) is a final object of \( \mathcal{C} \) implies that it is also a final object of \( \text{Alg}(\mathcal{C}) \) (Corollary 3.2.2.5); the dual assumption that \( 1 \) is an initial object of \( \mathcal{C} \) guarantees that it is final as an object of \( \text{Alg}(\mathcal{C}^{\text{op}}) \). Consequently, we will be free to ignore the distinction between associative algebras and augmented associative algebras.
Let us now describe the adjunction appearing in assertion (c) more explicitly (under the assumption that the unit object \(1\) is both initial and final). Suppose we are given an algebra object \(A \in \text{Alg}(\mathcal{C})\) and a coalgebra object \(C \in \text{Alg}(\mathcal{C}^{op})\). According to (c), we should have a canonical homotopy equivalence

\[
\text{Map}_{\text{Alg}(\mathcal{C})}(A, \text{Cobar}(C)) \simeq \text{Map}_{\text{Alg}(\mathcal{C}^{op})}(C, \text{Bar}(A)).
\]

We will prove this by identifying both sides with a classifying space for liftings of the pair \((A, C) \in \text{Alg}(\mathcal{C} \times \mathcal{C}^{op})\) to an algebra object of the twisted arrow \(\infty\)-category \(\text{TwArr}(\mathcal{C})\) of Construction 5.2.1.1. Our main result can be formulated more precisely as follows:

**Theorem 5.2.2.17.** Let \(\mathcal{C}\) be a monoidal \(\infty\)-category, so that \(\mathcal{C}^{op}\) and \(\text{TwArr}(\mathcal{C})\) inherit the structure of monoidal \(\infty\)-categories (see Example 5.2.2.23). Then:

1. The induced map \(\text{Alg}(\text{TwArr}(\mathcal{C})) \to \text{Alg}(\mathcal{C}) \times \text{Alg}(\mathcal{C}^{op})\) is a pairing of \(\infty\)-categories.
2. Assume that the unit object \(1 \in \mathcal{C}\) is final (so that every algebra object of \(\mathcal{C}\) is equipped with a canonical augmentation) and that \(\mathcal{C}\) admits geometric realizations of simplicial objects. Then the pairing \(\lambda\) is left representable, and therefore determines a functor \(\mathcal{D}_{\lambda} : \text{Alg}(\mathcal{C})^{op} \to \text{Alg}(\mathcal{C}^{op})\). The composite functor

\[
\text{Alg}(\mathcal{C})^{op} \xrightarrow{\mathcal{D}_{\lambda}} \text{Alg}(\mathcal{C}^{op}) \to \mathcal{C}^{op}
\]

is given by \(A \mapsto \text{Bar}(A)\).

3. Assume that the unit object \(1\) is initial (so that every coalgebra object of \(\mathcal{C}\) is equipped with a canonical augmentation) and that \(\mathcal{C}\) admits totalizations of cosimplicial objects. Then the pairing \(\lambda\) is right representable, and therefore determined a functor \(\mathcal{D}_{\lambda} : \text{Alg}(\mathcal{C}^{op})^{op} \to \text{Alg}(\mathcal{C})\). The composite functor

\[
\text{Alg}(\mathcal{C}^{op})^{op} \xrightarrow{\mathcal{D}_{\lambda}} \text{Alg}(\mathcal{C}) \to \mathcal{C}
\]

is given by \(C \mapsto \text{Cobar}(C)\).

**Remark 5.2.2.18.** Assertion (3) of Theorem 5.2.2.17 follows from assertion (2), applied to the opposite \(\infty\)-category \(\mathcal{C}^{op}\).

**Remark 5.2.2.19.** In the situation of Theorem 5.2.2.17, suppose that the unit object \(1\) is both initial and final, and that \(\mathcal{C}\) admits both geometric realizations of simplicial objects and totalizations of cosimplicial objects. Then the pairing \(\lambda : \text{Alg}(\text{TwArr}(\mathcal{C})) \to \text{Alg}(\mathcal{C}) \times \text{Alg}(\mathcal{C}^{op})\) is both left and right representable. We therefore obtain adjoint functors

\[
\text{Alg}(\mathcal{C}) \xrightarrow{\mathcal{D}_{\lambda}} \text{coAlg}(\mathcal{C}),
\]

given by the bar and cobar constructions, where \(\text{coAlg}(\mathcal{C}) = \text{Alg}(\mathcal{C}^{op})^{op}\) denotes the \(\infty\)-category of coalgebra objects of \(\mathcal{C}\).

More generally, if \(\mathcal{C}\) is an arbitrary monoidal \(\infty\)-category which admits geometric realizations of simplicial objects and totalizations of cosimplicial objects, then by applying Theorem 5.2.2.17 to the \(\infty\)-category \(\mathcal{C}^{1//1}\) we obtain an adjunction

\[
\text{Alg}^{\text{aug}}(\mathcal{C}) \xrightarrow{\text{Bar}} \text{coAlg}^{\text{aug}}(\mathcal{C}).
\]

The proof of Theorem 5.2.2.17 will require some general remarks about pairings between monoidal \(\infty\)-categories.

**Definition 5.2.2.20.** Let \(\mathcal{O}^{\otimes}\) be an \(\infty\)-operad. A *pairing of \(\mathcal{O}\)-monoidal \(\infty\)-categories* is a triple

\[
(p : \mathcal{O}^{\otimes} \to \mathcal{O}^{\otimes}, q : \mathcal{D}^{\otimes} \to \mathcal{O}^{\otimes}, \lambda^{\otimes} : \mathcal{M}^{\otimes} \to \mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathcal{D}^{\otimes})
\]

where \(p\) and \(q\) exhibit \(\mathcal{C}^{\otimes}\) and \(\mathcal{D}^{\otimes}\) as \(\mathcal{O}\)-monoidal \(\infty\)-categories and \(\lambda^{\otimes} : \mathcal{M}^{\otimes} \to \mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathcal{D}^{\otimes}\) is a \(\mathcal{O}\)-monoidal functor which is a categorical fibration and which induces a right fibration \(\Lambda_X : \mathcal{M}_X \to \mathcal{C}_X \times \mathcal{D}_X\) after taking the fiber over any object \(X \in \mathcal{O}\).
Remark 5.2.2.21. In the situation of Definition 5.2.2.20, we will generally abuse terminology by simply referring to the \( \mathcal{O} \)-monoidal functor \( \lambda^\otimes : M^\otimes \to \mathcal{C}^\otimes \times \mathcal{D}^\otimes \) as a pairing of monoidal \( \infty \)-categories. In the special case where \( \mathcal{O}^\otimes = \text{Ass}^\otimes \) is the associative \( \infty \)-operad, we will refer to \( \lambda^\otimes \) simply as a pairing of monoidal \( \infty \)-categories. If \( \mathcal{O}^\otimes = \text{Comm}^\otimes \) is the commutative \( \infty \)-operad, we will refer to \( \lambda^\otimes \) as a pairing of symmetric monoidal \( \infty \)-categories.

Remark 5.2.2.22. Let \( \mathcal{CPair} \) denote the \( \infty \)-category of pairings of \( \infty \)-categories (see Construction 5.2.1.14), and let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad. Unwinding the definitions, we see that the data of a pairing of \( \mathcal{O} \)-monoidal \( \infty \)-categories is equivalent to the data of a \( \mathcal{O} \)-monoid object of \( \mathcal{CPair} \).

Example 5.2.2.23. Recall that the forgetful functor \( (\lambda : M \to \mathcal{C} \times \mathcal{D}) \mapsto \mathcal{C} \) induces an equivalence \( \mathcal{CPair}^{\text{perf}} \to \mathcal{Cat}_\infty \), whose homotopy inverse is given on objects by \( \mathcal{C} \mapsto (\lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}}) \) (see Remark 5.2.1.20). Let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad and let \( \mathcal{C} \) be a \( \mathcal{O} \)-monoidal \( \infty \)-category, which we can identify with an \( \mathcal{O} \)-monoid object in the \( \infty \)-category \( \mathcal{Cat}_\infty \). It follows that the pairing \( \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}} \) admits the structure of a \( \mathcal{O} \)-monoid object of \( \mathcal{CPair}^{\text{perf}} \), which we can identify with a pairing of \( \mathcal{O} \)-monoidal \( \infty \)-categories

\[
\text{TwArr}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \times_{\mathcal{O}^\otimes}(\mathcal{C}^{\text{op}})^\otimes.
\]

Variant 5.2.2.24. Let \( \mathcal{O} \) be an \( \infty \)-operad, and suppose we are given a pairing of \( \mathcal{O} \)-monoidal \( \infty \)-categories

\[
\lambda^\otimes : M^\otimes \to \mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{fin}})} \mathcal{D}^\otimes,
\]

which we can identify with a \( \mathcal{O} \)-monoid object of the \( \infty \)-category \( \mathcal{CPair} \). Applying the right adjoint to the inclusion \( \mathcal{CPair}^R \hookrightarrow \mathcal{CPair} \), we see that the pairing \( \text{TwArr}_\lambda(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}} \) of Construction 5.2.1.24 can be promoted to a \( \mathcal{O} \)-monoid object of \( \mathcal{CPair}^R \), corresponding to another pairing of \( \mathcal{O} \)-monoidal \( \infty \)-categories

\[
\mu^\otimes : \text{TwArr}_\lambda(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \times_{(\mathcal{C}^{\text{op}})^\otimes}(\mathcal{C}^{\text{op}})^\otimes.
\]

We obtain a commutative diagram

\[
\begin{array}{ccc}
\text{TwArr}(\mathcal{C})^\otimes & \xleftarrow{\gamma} & \text{TwArr}_\lambda(\mathcal{C})^\otimes \\
\downarrow & & \downarrow \\
\mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{fin}})} (\mathcal{C}^{\text{op}})^\otimes & \xleftarrow{(\mathcal{C}^{\text{op}})^\otimes} & \mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{fin}})} (\mathcal{C}^{\text{op}})^\otimes
\end{array}
\]

where the horizontal maps are \( \mathcal{O} \)-monoidal functors.

Remark 5.2.2.25. Let \( \lambda^\otimes : M^\otimes \to \mathcal{C}^\otimes \times_{E_k^\infty} \mathcal{D}^\otimes \) be a pairing of \( E_k \)-monoidal \( \infty \)-categories and suppose that the underlying pairing \( \lambda : M \to \mathcal{C} \times \mathcal{D} \) is left representable. Then the localization functor \( L \) appearing in Remark 5.2.1.28 is compatible with the \( E_k \)-monoidal structure on \( \mathcal{C}^{\text{op}} \) (in the sense of Definition 2.2.1.6), so that the full subcategory \( \mathcal{C}^{\text{op}}_{\lambda\otimes} \subseteq (\mathcal{C}^{\text{op}})^\otimes \) inherits a symmetric monoidal structure. Moreover, since the projection map \( \mathcal{C}^{\text{op}}_{\lambda\otimes} \to \mathcal{C}^{\text{op}} \) carries \( L \)-equivalences to equivalences, it induces an \( E_k \)-monoidal functor \( \beta : (\mathcal{C}^{\text{op}})^{\text{op},\otimes} \to (\mathcal{C}^{\text{op}})^{\otimes} \). Since the underlying functor \( (\mathcal{C}^{\text{op}}_{\lambda\otimes})^{\text{op}} \to \mathcal{C}^{\text{op}} \) is an equivalence, we conclude that \( \beta \) is an equivalence. Let \( \text{TwArr}_{\lambda}(\mathcal{C}) \) denote the fiber product

\[
\text{TwArr}_{\lambda}(\mathcal{C}) \times (\mathcal{C}^{\text{op}})^{\text{op},\otimes},
\]

so that we have an equivalence of \( E_k \)-monoidal pairings

\[
\begin{array}{ccc}
\text{TwArr}(\mathcal{C})^\otimes & \xleftarrow{\gamma} & \text{TwArr}_{\lambda}(\mathcal{C})^\otimes \\
\downarrow & & \downarrow \\
\mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{fin}})} (\mathcal{C}^{\text{op}})^\otimes & \xleftarrow{(\mathcal{C}^{\text{op}})^\otimes} & \mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{fin}})} (\mathcal{C}^{\text{op}})^{\text{op},\otimes}
\end{array}
\]
Composing a homotopy inverse of this equivalence with \( \gamma \), we obtain a commutative diagram

\[
\begin{array}{ccc}
\text{TwArr}(\mathcal{C})^\otimes & \rightarrow & M^\otimes \\
\downarrow & & \downarrow \\
\mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{fin}})}(\mathcal{C}^\text{op})^\otimes & \rightarrow & \mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{fin}})} D^\otimes.
\end{array}
\]

Note that the horizontal maps in this diagram are merely lax \( \mathbb{E}_k \)-monoidal functors in general.

We can summarize the situation informally as follows: if we given a pairing of \( \mathbb{E}_k \)-monoidal \( \infty \)-categories

\[\lambda^\otimes : M^\otimes \rightarrow \mathcal{C}^\otimes \times_{\mathbb{E}_k^\otimes} D^\otimes\]

for which the underlying pairing \( \lambda : M \rightarrow \mathcal{C} \times D \) is left dualizable, then the duality map \( \mathcal{D}_\lambda : \mathcal{C}^\text{op} \rightarrow D \) of Construction 5.2.1.9 has the structure of a lax \( \mathbb{E}_k \)-monoidal functor.

**Remark 5.2.2.26.** Let \( \lambda^\otimes : M^\otimes \rightarrow \mathcal{C}^\otimes \times_{\mathbb{E}_k^\otimes} D^\otimes \) be a pairing of \( \mathbb{E}_k \)-monoidal \( \infty \)-categories. Then the induced map \( \text{Alg}_{/ \mathcal{O}}(M) \rightarrow \text{Alg}_{/ \mathcal{O}}(\mathcal{C}) \times \text{Alg}_{/ \mathcal{O}}(D) \) is a pairing of \( \infty \)-categories. This follows immediately from Corollary 3.2.2.3.

In particular, if \( \lambda^\otimes : M^\otimes \rightarrow \mathcal{C}^\otimes \times_{\text{Ass}^\otimes} D^\otimes \) is a pairing of monoidal \( \infty \)-categories, then it induces a pairing of \( \infty \)-categories

\[\text{Alg}(\lambda) : \text{Alg}(M) \rightarrow \text{Alg}(\mathcal{C}) \times \text{Alg}(D)\]

The key step in the proof of Theorem 5.2.2.17 is to establish a criterion which can be used to show that \( \text{Alg}(\lambda) \) is left (or right) representable.

**Proposition 5.2.2.27.** Let \( \lambda^\otimes : M^\otimes \rightarrow \mathcal{C}^\otimes \times_{\text{Ass}^\otimes} D^\otimes \) be a pairing of monoidal \( \infty \)-categories. Assume that:

1. If \( 1 \) denotes the unit object of \( D \), then the right fibration \( M \times_D \{1\} \rightarrow \mathcal{C} \) is a categorical equivalence.
2. The underlying pairing \( \lambda : M \rightarrow \mathcal{C} \times D \) is left representable.
3. The \( \infty \)-category \( D \) admits totalizations of cosimplicial objects.

Then the induced pairing \( \text{Alg}(\lambda) : \text{Alg}(M) \rightarrow \text{Alg}(\mathcal{C}) \times \text{Alg}(D) \) is left representable.

The proof of Proposition 5.2.2.27 will occupy our attention for most of this section. We begin by treating an easy special case.

**Proposition 5.2.2.28.** Let \( \lambda^\otimes : M^\otimes \rightarrow \mathcal{C}^\otimes \times_{\text{Ass}^\otimes} D^\otimes \) be a pairing between monoidal \( \infty \)-categories, and assume that the underlying pairing of \( \infty \)-categories \( \lambda : M \rightarrow \mathcal{C} \times D \) is left representable. Let \( A \in \text{Alg}(\mathcal{C}) \) be a trivial algebra object of \( \mathcal{C} \) (see §3.2.1). Then:

1. There exists a left universal object of \( \text{Alg}(M) \) lying over \( A \in \text{Alg}(\mathcal{C}) \).
2. An object \( M \in \text{Alg}(M) \) lying over \( A \in \text{Alg}(\mathcal{C}) \) is left universal if and only if the image of \( M \) in \( M \) is left universal (with respect to the pairing \( \lambda : M \rightarrow \mathcal{C} \times D \)).

**Proof.** We can identify \( \text{Alg}(M) \times_{\text{Alg}(\mathcal{C})} \{A\} \) with \( \text{Alg}(N) \), where \( N^\otimes \) denotes the monoidal \( \infty \)-category \( M^\otimes \times_{\mathcal{C}^\otimes} \text{Ass}^\otimes \). An object of \( \text{Alg}(M) \times_{\text{Alg}(\mathcal{C})} \{A\} \) is left universal if and only if it is a final object of \( \text{Alg}(N) \). Since \( \lambda \) is left representable, \( N \) has a final object. Assertions (1) and (2) are therefore immediate consequences of Corollary 3.2.2.5.

To prove Proposition 5.2.2.27 in general, we must show that an arbitrary algebra object \( A \in \text{Alg}(\mathcal{C}) \) can be lifted to a left universal object of \( \text{Alg}(M) \). This object is not as easy to find: for example, its image in \( M \) is generally not left universal for the underlying pairing \( \lambda : M \rightarrow \mathcal{C} \times D \). In order to construct it, we would like to reduce to the situation where \( A \) is a trivial algebra object of \( \mathcal{C} \). We will accomplish this by replacing \( \mathcal{C} \) by another monoidal \( \infty \)-category having \( A \) as the unit object: namely, the \( \infty \)-category \( \text{Mod}_A^\text{st}\mathcal{C} \simeq A \text{BMod}_A(\mathcal{C}) \) (see Theorem 4.4.1.28).
Lemma 5.2.2.29. Let \( \lambda^\circ : M^\circ \to E^\circ \times_{\text{Ass}} D^\circ \) be a pairing of monoidal \( \infty \)-categories, and let \( M \in \text{Alg}(M) \) have image \( (A,B) \in \text{Alg}(E) \times \text{Alg}(D) \). Then the induced map

\[
\text{Mod}^\text{Ass}_M(M)^\circ \to \text{Mod}^\text{Ass}_A(E)^\circ \times_{\text{Ass}} \text{Mod}^\text{Ass}_B(D)^\circ
\]

is also a pairing of monoidal \( \infty \)-categories.

Proof. It will suffice to show that the map \( M \text{BMod}_M(M) \to \text{BMod}_A(C) \times \text{BMod}_B(D) \) is a right fibration. This map is a pullback of the categorical fibration

\[
\theta : \text{BMod}(M) \to (\text{BMod}(C) \times \text{BMod}(D)) \times_{\text{Alg}(C)^2 \times \text{Alg}(D)^2} \text{Alg}(M)^2.
\]

We will show that \( \theta \) is a right fibration. Let

\[
\theta' : (\text{BMod}(C) \times \text{BMod}(D)) \times_{\text{Alg}(C)^2 \times \text{Alg}(D)^2} \text{Alg}(M)^2 \to \text{BMod}(C) \times \text{BMod}(D)
\]

be the projection map. Since \( \theta \) is a categorical fibration, it will suffice to show that \( \theta' \) and \( \theta' \circ \theta \) are right fibrations. The map \( \theta' \) is a pullback of the forgetful functor \( \text{Alg}(\lambda) : \text{Alg}(M) \to \text{Alg}(C) \times \text{Alg}(D) \). We are therefore reduced to proving that \( \text{Alg}(\lambda) \) and \( \theta' \circ \theta \) are right fibrations, which follows immediately from Corollary 5.2.2.3.

Proposition 5.2.2.30. Let \( \lambda^\circ : M^\circ \to E^\circ \times_{\text{Ass}} D^\circ \) be a pairing of monoidal \( \infty \)-categories. Let \( M \in \text{Alg}(M) \) have image \( (A,B) \in \text{Alg}(E) \times \text{Alg}(D) \). We will abuse notation by identifying \( A \) and \( B \) with their images in \( E \) and \( D \), respectively. Assume that \( B \) is a trivial algebra object of \( D \) and that, for every object \( C \in E \), the Kan complex \( \lambda^{-1}\{(C,B)\} \subseteq M \) is contractible. Then the forgetful functor \( \text{Alg}(\text{Mod}^\text{Ass}_M(M)) \to \text{Alg}(M) \) carries left universal objects of \( \text{Alg}(\text{Mod}^\text{Ass}_M(M)) \) to left universal objects of \( \text{Alg}(M) \).

Proof. It will suffice to show that for every \( A' \in \text{Alg}(\text{Mod}^\text{Ass}_A(E)) \) isomorphic to \( \text{Alg}(E) \), the left fibration \( \text{Alg}(\text{Mod}^\text{Ass}_M(M)) \times_{\text{Alg}(\text{Mod}^\text{Ass}_A(E))} \{(A',B')\} \to \text{Alg}(M) \times_{\text{Alg}(E)} \{(A'_0,B'_0)\} \) is an equivalence of \( \infty \)-categories (and therefore carries final objects to final objects). Since \( B \) is a trivial algebra object of \( D \), the forgetful functor \( \text{Alg}(\text{Mod}^\text{Ass}_B(D)) \to \text{Alg}(D) \) is an equivalence of \( \infty \)-categories. It will therefore suffice to show that for each \( B' \in \text{Alg}(\text{Mod}^\text{Ass}_B(D)) \) having image \( B'_0 \) in \( \text{Alg}(D) \), the induced map

\[
\text{Alg}(\text{Mod}^\text{Ass}_M(M)) \times_{\text{Alg}(\text{Mod}^\text{Ass}_A(E))} \{(A',B')\} \to \text{Alg}(M) \times_{\text{Alg}(E)} \{(A'_0,B'_0)\}
\]

is a homotopy equivalence of Kan complexes. Using Corollary 3.4.1.7, we can identify the domain of this map with \( \text{Alg}(M) \times_{\text{Alg}(E)} \{(A',B')\} \). We will conclude the proof by showing that \( M \in \text{Alg}(M) \) is \( p \)-initial, where \( p : \text{Alg}(M) \to \text{Alg}(E) \times \text{Alg}(D) \) denotes the projection. Since \( p \) is a right fibration, we are reduced to showing that the Kan complex \( \text{Alg}(M) \times_{\text{Alg}(E)} \{(A,B)\} \) is contractible. This Kan complex is given by a homotopy fiber of the map \( \phi : \text{Alg}(N) \to \text{Alg}(E) \), where \( N = M \times_D \{(B)\} \). We now observe that \( \phi \) is a categorical equivalence, since the monoidal functor \( N \to E \) is a categorical equivalence (by virtue of the fact that it is a right fibration whose fibers are contractible Kan complexes).

Notation 5.2.2.31. Let \( \lambda^\circ : M^\circ \to E^\circ \times_{\text{Ass}} D^\circ \) be a pairing of monoidal \( \infty \)-categories. If \( M \in \text{Alg}(M) \) has image \( (A,B) \in \text{Alg}(E) \times \text{Alg}(D) \), we let \( \lambda_M \) denote the induced pairing \( \text{Mod}^\text{Ass}_M(M) \to \text{Mod}^\text{Ass}_A(E) \times \text{Mod}^\text{Ass}_B(D) \).

Lemma 5.2.2.32. Let \( \lambda^\circ : M^\circ \to E^\circ \times_{\text{Ass}} D^\circ \) be a pairing of monoidal \( \infty \)-categories, and let \( M \in \text{Alg}(M) \) be an object having image \( (A,B) \in \text{Alg}(E) \times \text{Alg}(D) \), where \( B \) is a trivial algebra object of \( D \). Let \( F : M \to \text{Mod}^\text{Ass}_A(E) \simeq \text{BMod}_M(M) \) be a left adjoint to the forgetful functor, given by \( V \mapsto V \otimes_M V \otimes_M \) (see Corollary 4.3.3.14). Then \( F \) carries left universal objects of \( M \) (with respect to the pairing \( \lambda : M \to E \times D \)) to left universal objects of \( \text{Mod}^\text{Ass}_A(E) \times \text{Mod}^\text{Ass}_B(D) \).
\textbf{Proof.} Let $F' : \mathcal{E} \to \text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{E})$ and $F'' : \mathcal{D} \to \text{Mod}^{\text{Ass}}_{\mathcal{B}}(\mathcal{D})$ be left adjoints to the forgetful functors $G' : \text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{E}) \to \mathcal{E}$ and $G'' : \text{Mod}^{\text{Ass}}_{\mathcal{B}}(\mathcal{D}) \to \mathcal{D}$. Modifying $F$ by a homotopy if necessary, we may assume that the diagram

\[
\begin{array}{ccc}
\mathcal{M} & \xrightarrow{F} & \text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{M}) \\
\downarrow & & \downarrow \\
\mathcal{E} \times \mathcal{D} & \xrightarrow{F' \times F''} & \text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{E}) \times \text{Mod}^{\text{Ass}}_{\mathcal{B}}(\mathcal{D})
\end{array}
\]

is commutative. For each $C \in \mathcal{E}$, $F$ induces a functor

\[f : \mathcal{M} \times C \to \text{Mod}^{\text{Ass}}_{\mathcal{M}}(\mathcal{M}) \times_{\text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{E})} \{F'(C)\}.
\]

We wish to show that $f$ preserves final objects. In fact, we will show that $f$ is an equivalence of \(\infty\)-categories. Note first that $f$ has a right adjoint $g$, given by composing the forgetful functor $\text{Mod}^{\text{Ass}}_{\mathcal{M}}(\mathcal{M}) \times_{\text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{E})} \{F'(C)\} \to \mathcal{M} \times \mathcal{E} \{G'(\cdot)\}$ with the pullback functor $\mathcal{M} \times \mathcal{E} \{G'(\cdot)\} \to \mathcal{M} \times \mathcal{E} \{G'(\cdot)\}$ associated to the unit map $C \to (G' \circ F')(C)$. Let $u : \text{id} \to g \circ f$ be the unit map. For every object $V \in \mathcal{M} \times \mathcal{E}$, having $D \in \mathcal{D}$, the pullback functor $V \to ((g \circ f)(V))$ has image in $\mathcal{D}$ equivalent to the unit map $D \to (G' \circ F')(D) \simeq B \otimes D \otimes B$ in $\mathcal{D}$. Since $B$ is a trivial algebra, we conclude that the image of $u_V$ in $\mathcal{D}$ is an equivalence. Because the map $\mathcal{M} \times \mathcal{E} \{C\} \to \mathcal{D}$ is a right fibration, we conclude that $u_V$ is an equivalence. A similar argument shows that the counit map $v : f \circ g \to \text{id}$ is an equivalence of functors, so that $g$ is homotopy inverse to $f$ as desired. \(\square\)

\textbf{Lemma 5.2.2.33.} Let $\lambda^\otimes : \mathcal{M}^\otimes \to \mathcal{E}^\otimes \times_{\text{Ass}} \mathcal{D}^\otimes$ be a pairing of monoidal \(\infty\)-categories and let $M \in \text{Alg}(\mathcal{M})$ be an algebra having image $(A, B) \in \text{Alg}(\mathcal{E}) \times \text{Alg}(\mathcal{D})$, where $B$ is a trivial algebra object of $\mathcal{D}$. Let $1$ denote the unit object of $\mathcal{M}$ (which we regard as a trivial algebra object of $\mathcal{M}$) and suppose we are given an augmentation $\epsilon : M \to 1$. Then the induced map

\[\mathcal{M} \simeq \text{Mod}^{\text{Ass}}_{\mathcal{M}}(\mathcal{M}) \to \text{Mod}^{\text{Ass}}_{\mathcal{M}}(\mathcal{M})
\]

is right representable, with respect to the pairing $\lambda^\otimes$.

\textbf{Proof.} For each object $D \in \mathcal{D}$, let $\mathcal{M}_D$ denote the fiber $\mathcal{M} \times \mathcal{D} \{D\}$. Then each $\mathcal{M}_D$ can be regarded as an \(\infty\)-category bitensored over $\mathcal{M}_1$, where $1$ denotes the unit object of $\mathcal{D}$. Moreover, we have a canonical equivalence

\[\text{Mod}^{\text{Ass}}_{\mathcal{M}}(\mathcal{M}) \times_{\text{Mod}^{\text{Ass}}_{\mathcal{D}}(\mathcal{D})} \{D\} \simeq M \otimes \text{Mod}_M(M_D).
\]

It will therefore suffice to show that the canonical map

\[M_D \simeq 1 \otimes \text{Mod}_M(M_D) \to M \otimes \text{Mod}_M(M_D)
\]

preserves final objects. This follows from Corollary 4.3.3.3. \(\square\)

\textbf{Corollary 5.2.2.34.} Let $\lambda^\otimes : \mathcal{M}^\otimes \to \mathcal{E}^\otimes \times_{\text{Ass}} \mathcal{D}^\otimes$ be a pairing of monoidal \(\infty\)-categories, let $M$ be an algebra object of $\mathcal{M}$ having image $(A, B) \in \text{Alg}(\mathcal{E}) \times \text{Alg}(\mathcal{D})$. Assume that $B$ is a trivial algebra object of $\mathcal{D}$, that the underlying pairing of \(\infty\)-categories $\lambda : \mathcal{M} \to \mathcal{E} \times \mathcal{D}$ is right representable, and that there exists an augmentation $\epsilon : M \to 1$ on $M$. Then the induced pairing $\lambda_M : \text{Mod}^{\text{Ass}}_{\mathcal{M}}(\mathcal{M}) \to \text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{E}) \times \text{Mod}^{\text{Ass}}_{\mathcal{B}}(\mathcal{D})$ is right representable. Moreover, the duality functor $\mathcal{D}_M$ can be identified with the composition

\[\text{Mod}^{\text{Ass}}_{\mathcal{B}}(\mathcal{D}) \simeq \mathcal{D} \to \mathcal{E} \xrightarrow{\epsilon} \text{Mod}^{\text{Ass}}_{\mathcal{A}}(\mathcal{E}),
\]

where the last map is induced by the augmentation $\epsilon$.

\textbf{Proof.} Combine Lemma 5.2.2.33 with Proposition 5.2.1.17. \(\square\)
Example 5.2.2.35. Let $\mathcal{E}$ be a monoidal $\infty$-category with unit object 1, and consider the pairing of monoidal
$\infty$-categories
$$\lambda^\oplus : \text{TwArr}(\mathcal{E})^\oplus \to \mathcal{E}^\oplus \times_{\mathcal{E}^\oplus} (\mathcal{E}^\text{op})^\oplus$$
of Example 5.2.2.23. Let $A$ be an augmented algebra object of $\mathcal{E}$. Then we can identify $A$ with an algebra object
of the monoidal $\infty$-category $\mathcal{E}_A \simeq \text{TwArr}(\mathcal{E}) \times_{\mathcal{E}^\oplus} \{1\}$; let $M$ denote the image of this algebra object
in $\text{TwArr}(\mathcal{E})$. It follows from Corollary 5.2.2.34 that the pairing
$$\lambda_M : \text{Mod}^A_M(\text{TwArr}(\mathcal{E})) \to \text{Mod}^A_{\mathcal{E}}(\mathcal{E}) \times \text{Mod}^A_{\mathcal{E}^\text{op}}(\mathcal{E}^\text{op})$$is right representable, and that the associated duality functor
$$\mathcal{D}^M_\lambda : \mathcal{E} \simeq \text{Mod}^A_1(\mathcal{E})^\text{op} \to \text{Mod}^A_1(\mathcal{E})$$is homotopic to the forgetful functor determined by the augmentation $\epsilon$.

We will need the following general fact about limits of $\infty$-categories:

Proposition 5.2.2.36. Let $\mathcal{E}$ be an $\infty$-category and $\chi : \mathcal{E} \to \text{Cat}_{\infty}$ a functor, classifying a coCartesian
fibration $q : \mathcal{D} \to \mathcal{E}^\text{op}$. Then $\chi$ is a limit diagram if and only if the following conditions are satisfied:

(a) Let $v$ denote the cone point of $\mathcal{E}$, and for each object $C \in \mathcal{E}$ let $e_C : D_v \to D_C$ be the functor induced
by the unique morphism $f_C : v \to C$ in $\mathcal{E}$. Then the functors $e_C$ are jointly conservative: that is, if $\alpha$ is a morphism in $D_v$
such that each $e_C(\alpha)$ is an equivalence in $D_C$, then $\alpha$ is an equivalence in $D_v$.

(b) Let $X \in \text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{D})$ be a functor which carries each morphism in $\mathcal{E}$ to a $q$-coCartesian morphism in
$\mathcal{D}$. Then $X$ can be extended to a $q$-limit diagram $\overline{X} \in \text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{D})$. Moreover, $\overline{X}$ carries each $f_C$
out to a $q$-coCartesian morphism in $\mathcal{D}$.

Moreover, if these conditions are satisfied, then a diagram $\overline{X} \in \text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{D})$ is a $q$-limit diagram, provided
that it carries each morphism in $\mathcal{E}$ to a $q$-coCartesian morphism in $\mathcal{D}$.

Proof. Let $\mathcal{E}$ denote the full subcategory of $\text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{D})$ spanned by those functors which carry each morphism
in $\mathcal{E}$ to a $q$-coCartesian morphism in $\mathcal{D}$, let $\overline{\mathcal{E}}$ be the full subcategory of $\text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{D})$ spanned by
those functors which carry each morphism in $\mathcal{E}$ to a $q$-coCartesian morphism in $\mathcal{D}$, and let $\overline{\overline{\mathcal{E}}}$ be the full
subcategory of $\text{Fun}_{\mathcal{E}}(\mathcal{E}, \mathcal{D})$ spanned by those functors $\overline{X}$ which are $q$-limit diagrams having the property
that $\overline{X}|_{\mathcal{E}}$ belongs to $\mathcal{E}$. Using Proposition T.3.3.3.1, we see that $\chi$ is a limit diagram if and only if the
restriction functor $r : \overline{\mathcal{E}} \to \mathcal{E}$ is an equivalence of $\infty$-categories. Suppose first that this condition is satisfied.
Assertion (a) is then obvious (it is equivalent to the requirement that the functor $r$ is conservative). We will
show that the last assertion is satisfied: that is, we have an inclusion $\overline{\mathcal{E}} \subseteq \overline{\overline{\mathcal{E}}}$. It follows that every $X \in \mathcal{E}$
can be extended to a $q$-limit diagram, so that (by Proposition T.4.3.2.15) the restriction functor $\overline{\mathcal{E}} \to \mathcal{E}$
is a trivial Kan fibration. A two-out-of-three argument then shows that the inclusion $\overline{\mathcal{E}} \subseteq \overline{\overline{\mathcal{E}}}$ is an equivalence
of $\infty$-categories, so that $\overline{\mathcal{E}} = \overline{\overline{\mathcal{E}}}$. This proves (b).

To prove that $\mathcal{E} \subseteq \overline{\mathcal{E}}$, consider an arbitrary diagram $\overline{X} \in \overline{\mathcal{E}}$ and let $X = \overline{X}|_{\mathcal{E}}$. To show that $\overline{X}$ is a $q$-limit
diagram, it suffices to show that for every object $D \in D_v$ the canonical morphism $\phi : \{D\} \times D^v \to \{D\} \times D^X$
is a homotopy equivalence of Kan complexes. Choose a diagram $\overline{\overline{Y}} \in \overline{\mathcal{E}}$ with $\overline{\overline{Y}}(v) = D$ (such a diagram
exists and is essentially unique, by virtue of Proposition T.4.3.2.15), and let $Y = \overline{\overline{Y}}|_{\mathcal{E}}$. Then $\phi$ is equivalent
to the restriction map
$$\text{Map}_{\mathcal{E}}(\overline{\overline{Y}}, \overline{X}) \to \text{Map}_{\mathcal{E}}(Y, X),$$
which is a homotopy equivalence by virtue of our assumption that the functor $r$ is fully faithful.

Now suppose that conditions (a) and (b) are satisfied; we wish to prove that $r$ is an equivalence of $\infty$-
categories. Condition (b) guarantees that $\overline{\overline{\mathcal{E}}} \subseteq \mathcal{E}$ and, by virtue of Proposition T.4.3.2.15, that $r|_{\overline{\overline{\mathcal{E}}}}$
is a trivial Kan fibration. To complete the proof, it suffices to show that the reverse inclusion $\overline{\mathcal{E}} \subseteq \overline{\overline{\mathcal{E}}}$ holds. Fix
\( \overline{X} \in \mathcal{E} \), let \( X = \overline{X}|_\mathcal{E} \), and let \( \overline{X}' \in \mathcal{E}' \) be a \( q \)-limit of the diagram \( X \). We have a canonical map \( \alpha : \overline{X} \to \overline{X}' \) which induces the identity map \( \text{id}_X : X \to X \) in \( \mathcal{E} \). To complete the proof, it suffices to show that \( \alpha \) is an equivalence; that is, the map \( \alpha : \overline{X}(v) \to \overline{X}'(v) \) is an equivalence in the \( \infty \)-category \( \mathcal{D}_v \). This is an immediate consequence of assumption \((a)\).

**Corollary 5.2.2.37.** Let \( f : \overline{\mathcal{C}} \to \mathcal{C} \) be a right fibration of \( \infty \)-categories, classified by a map \( \chi : \mathcal{E}^\text{op} \to \mathcal{S} \) and suppose we are given a diagram \( \overline{\mathcal{P}} : K^\text{op} \to \mathcal{C} \). The following conditions are equivalent:

1. For every commutative diagram \( \sigma : 
   \begin{array}{ccc}
   K & \xrightarrow{\eta} & \overline{\mathcal{C}} \\
   \downarrow{\bar{\eta}} & & \downarrow{f} \\
   K^\text{op} & \xrightarrow{\mathcal{P}} & \mathcal{C}
   \end{array}
\)
   there exists an extension \( \bar{\eta} \) as indicated, which is an \( f \)-colimit diagram.

2. The restriction \( \chi|_{(K^\text{op})^\text{op}} \) is a limit diagram in \( \mathcal{S} \).

If \( \mathcal{P} \) is a colimit diagram in \( \mathcal{C} \), then these conditions are equivalent to the following:

3. For every diagram \( \sigma \) as in (1), the diagram \( q : K \to \overline{\mathcal{C}} \) can be extended to a colimit diagram in \( \mathcal{C} \), whose image in \( \mathcal{C} \) is also a colimit diagram.

**Proof.** The equivalence of (1) and (2) follows from Proposition 5.2.2.36, and the equivalence of (1) and (3) from Proposition T.4.3.1.5. \( \square \)

**Lemma 5.2.2.38.** Let \( \lambda^\otimes : \mathcal{M}^\otimes \to \mathcal{C}^\otimes \times \text{Ass} \otimes \mathcal{D}^\otimes \) be a pairing of monoidal \( \infty \)-categories, and let \( M \in \text{Alg}(\mathcal{M}) \) be an object having image \( (A, B) \in \text{Alg}(\mathcal{C}) \times \text{Alg}(\mathcal{D}) \). Assume that:

1. The object \( B \in \text{Alg}(\mathcal{D}) \) is a trivial algebra in \( \mathcal{D} \).

2. The pairing \( \lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D} \) is left representable.

3. The \( \infty \)-category \( \mathcal{D} \) admits totalizations of cosimplicial objects.

Then the induced pairing \( \lambda_M : \text{Mod}^\text{Ass}_M(\mathcal{M}) \to \text{Mod}^\text{Ass}_A(\mathcal{C}) \times \text{Mod}^\text{Ass}_B(\mathcal{D}) \) is left representable.

**Proof.** Fix an object \( C \in \text{Mod}^\text{Ass}_A(\mathcal{C}) \); we wish to show that \( C \) can be lifted to a left universal object of \( \text{Mod}^\text{Ass}_M(\mathcal{M}) \). Let \( g : \text{Mod}^\text{Ass}_A(\mathcal{C}) \simeq \text{BMod}_A(\mathcal{C}) \to \mathcal{C} \) denote the forgetful functor, and let \( f \) denote its left adjoint. Example 4.7.4.9 implies that \( g \) exhibits \( \text{Mod}^\text{Ass}_A(\mathcal{C}) \) as monadic over \( \mathcal{C} \). Invoking Proposition 4.7.4.14, we deduce that there exists a \( g \)-split simplicial object \( C_* \) of \( \text{Mod}^\text{Ass}_A(\mathcal{C}) \) having colimit \( C \), where each \( C_n \) belongs to the essential image of the functor \( f \).

Fix an object \( D \in \mathcal{D} \), let \( \mathcal{M}_D \) denote the fiber product \( \mathcal{M} \times_{\mathcal{D}} \{D\} \), and consider the induced right fibration \( \theta : \mathcal{M}_D \to \mathcal{C} \). Condition (1) implies that \( D \) lifts uniquely to an object \( \overline{D} \in \text{Mod}^\text{Ass}_B(\mathcal{D}) \). Set \( \mathcal{N} = \text{Mod}^\text{Ass}_M(\mathcal{M}) \times_{\text{Mod}^\text{Ass}_B(\mathcal{D})} \{\overline{D}\} \); so that the projection map \( \mathcal{N} \to \text{Mod}^\text{Ass}_A(\mathcal{C}) \) is a right fibration classified by a map \( \chi_D : \text{Mod}^\text{Ass}_A(\mathcal{C})^\text{op} \to \mathcal{S} \). We claim that the canonical map \( \chi_D(C) \to \lim \chi_D(C_*) \) is a homotopy equivalence.

To prove this, it will suffice (Corollary 5.2.2.37) to show that for every simplicial object \( N_* \) of \( \mathcal{N} \) lifting \( C_* \), there exists a geometric realization \( |N_*| \) which is preserved by the forgetful functor \( q : \mathcal{N} \to \text{Mod}^\text{Ass}_A(\mathcal{C}) \). Let \( p : \mathcal{N} \to \mathcal{M}_D \) denote the forgetful functor. Since \( q' : \mathcal{M}_D \to \mathcal{C} \) is a right fibration, it follows from Corollary 4.7.3.11 that \( p(N_*) \) is a split simplicial object of \( \mathcal{M}_D \). Since \( \mathcal{N} \) can be identified with an \( \infty \)-category of bimodule objects of \( \mathcal{M}_D \), Variant 4.7.3.6 implies that \( N_* \) admits a colimit \( N \) in \( \mathcal{N} \) which is preserved by the functor \( p \). Because \( p(N_*) \) is split, we conclude that the colimit of \( N_* \) is preserved by \( q' \circ p \simeq p' \circ q \). Applying Corollary 4.7.3.11 again, we conclude that the colimit of \( N_* \) is preserved by \( q \).
The pairing $\lambda_\mathcal{M}$ is classified by a functor $\chi' : \text{Mod}_{\mathcal{A}}^{\text{Ass}}(\mathcal{C})^{\text{op}} \to \text{Fun}((\text{Mod}_{\mathcal{B}}^{\text{Ass}}(\mathcal{D}))^{\text{op}}, \mathcal{S})$. The preceding arguments show that $\chi'(\mathcal{C}) \simeq \varprojlim \chi'(\mathcal{C}_\bullet)$. We wish to prove that $\chi'(\mathcal{C})$ is representable. Using condition (3), we are reduced to proving that each $\chi'(\mathcal{C}_n)$ is a representable functor. This follows immediately from (2) together with Lemma 5.2.2.32.

Corollary 5.2.2.39. Let $\mathcal{C}$ be a monoidal $\infty$-category which admits geometric realizations of simplicial objects, let $\mathcal{A}$ be an augmented associative algebra object of $\mathcal{C}$, and let $M \in \text{Alg}(\text{TwArr}(\mathcal{C}))$ be as in Example 5.2.2.35. Then the pairing

$$\lambda_\mathcal{M} : \text{Mod}_{\mathcal{A}}^{\text{Ass}}(\text{TwArr}(\mathcal{C})) \to \text{Mod}_{\mathcal{A}}^{\text{Ass}}(\mathcal{C}) \times \text{Mod}_{\mathcal{1}}^{\text{Ass}}(\mathcal{C}^{\text{op}})$$

is left representable. Moreover, the associated duality functor

$$\mathcal{D}_{\lambda_\mathcal{M}} : \text{Mod}_{\mathcal{A}}^{\text{Ass}}(\mathcal{C}) \to \text{Mod}_{\mathcal{1}}^{\text{Ass}}(\mathcal{C}^{\text{op}})^{\text{op}} \simeq \mathcal{C}$$

is left adjoint to the forgetful functor $\mathcal{C} \to \text{Mod}_{\mathcal{A}}^{\text{Ass}}(\mathcal{C})$ induced by the augmentation on $\mathcal{A}$. In particular, there is a canonical equivalence $\mathcal{D}_{\lambda_\mathcal{M}}(\mathcal{A}) \simeq \text{Bar}(\mathcal{A})$ in the $\infty$-category $\mathcal{C}$.

Proof. Combine Lemma 5.2.2.38 with Example 5.2.2.35.

Proof of Proposition 5.2.2.27. Let $A \in \text{Alg}(\mathcal{C})$; we wish to show that there is a left universal object of $\text{Alg}(M)$ lying over $A$. Let $B$ be a trivial algebra object of $\mathcal{D}$, so that condition (1) implies that the right fibration $M \times_{\mathcal{D}} \{B\} \to \mathcal{C}$ is an equivalence of (monoidal) $\infty$-categories. It follows that the pair $(A, B)$ can be lifted to an object $M \in \text{Alg}(M)$ in an essentially unique way. Using Proposition 5.2.2.30, we are reduced to proving that there exists a left universal object of $\text{Alg}(\text{Mod}_{\mathcal{M}}^{\text{Ass}}(\mathcal{M}))$ lying over $A \in \text{Alg}(\text{Mod}_{\mathcal{A}}^{\text{Ass}}(\mathcal{C}))$. Since $A$ is the unit object of $\text{Mod}_{\mathcal{A}}^{\text{Ass}}(\mathcal{C})$, it suffices to lift $A$ to a left universal object of $\text{Mod}_{\mathcal{M}}^{\text{Ass}}(\mathcal{M})$ (Proposition 5.2.2.28). The existence of such a lift now follows from Lemma 5.2.2.38.

Proof of Theorem 5.2.2.17. Let $\mathcal{C}$ be a monoidal $\infty$-category and let $\text{Alg}(\lambda) : \text{Alg}(\text{TwArr}(\mathcal{C})) \to \text{Alg}(\mathcal{C}) \times \text{Alg}(\mathcal{C}^{\text{op}})$ be the canonical map. Assertion (1) of the Theorem follows from Remark 5.2.2.26. We will give the proof of assertion (2); assertion (3) will then follow by symmetry. Assume that the unit object $1 \in \mathcal{C}$ is final and that $\mathcal{C}$ admits geometric realizations of simplicial objects. Then the pairing of monoidal $\infty$-categories $\lambda^\circ : \text{TwArr}(\mathcal{C})^\circ \to \mathcal{C}^\circ \times_{\text{Ass}} (\mathcal{C}^{\text{op}})^\circ$ satisfies the hypotheses of Proposition 5.2.2.27, so that $\text{Alg}(\lambda)$ is left representable. In particular, we have a duality functor $\mathcal{D}_{\text{Alg}(\lambda)} : \text{Alg}(\mathcal{C})^{\text{op}} \to \text{Alg}(\mathcal{C}^{\text{op}})$.

Let $A$ be an algebra object of $\mathcal{C}$. Since the unit object $1 \in \mathcal{C}$ is final, there exists an essentially unique augmentation $\epsilon : A \to 1$. Let $M \in \text{Alg}(\text{TwArr}(\mathcal{C}))$ be as in Example 5.2.2.35. The proof of Proposition 5.2.2.27 shows that, as an object of the $\infty$-category $\mathcal{C}$, we can identify $\mathcal{D}_{\text{Alg}(\lambda)}(A)$ with $\mathcal{D}_{\lambda_\mathcal{M}}(A)$, which is canonically equivalent to $\text{Bar}(A)$ by virtue of Corollary 5.2.2.39.

5.2.3 Iterated Bar Constructions

Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category which admits geometric realizations of simplicial objects. In §5.2.2, we saw that the construction $A \mapsto \text{Bar}(A)$ determines a functor from the $\infty$-category of augmented algebra objects of $\mathcal{C}$ to the $\infty$-category of augmented coalgebra objects of $\mathcal{C}$. In this section, we will prove analogous results for $E_k$-algebras for $1 \leq k < \infty$. Our starting point is the following generalization of Proposition 5.2.2.27:

Theorem 5.2.3.1. Let $1 \leq k < \infty$ and let $\lambda^\circ : \mathcal{M}^\circ \to \mathcal{C}^\circ \times_{E_k} \mathcal{D}^\circ$ be a pairing of $E_k$-monoidal $\infty$-categories. Assume that:

1. If $1$ denotes the unit object of $\mathcal{D}$, then the right fibration $\mathcal{M} \times_{\mathcal{D}} \{1\} \to \mathcal{C}$ is a categorical equivalence.
2. The underlying pairing $\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ is left representable.
3. The $\infty$-category $\mathcal{D}$ admits totalizations of cosimplicial objects.
Then the induced pairing $\text{Alg}_{/E_k}(\lambda) : \text{Alg}_{/E_k}(M) \to \text{Alg}_{/E_k}(C) \times \text{Alg}_{/E_k}(D)$ is left representable.

One can attempt to prove this using the strategy outlined in §5.2.2; the main obstacle is in proving that $\infty$-categories of the form $\text{Mod}_{E_k}^\infty(C)$ are monadic over $C$. We will adopt a different approach which avoids this issue, using the Additivity Theorem to reduce to the case $k = 1$.

**Remark 5.2.3.2.** If the unit object of $D$ is initial, then Theorem 5.2.3.1 is also valid when $k = 0$; we leave the proof to the reader.

**Proof of Theorem 5.2.3.1.** We proceed by induction on $k$. When $k = 1$, the desired result follows from Proposition 5.2.2.27 (see Example 5.1.0.7). Let us therefore assume that $k > 1$. Consider the bifunctor of $\infty$-operads $E_{k-1}^\infty \times E_1^\infty \to E_k^\infty$ studied in §5.1.2. Using Remark 5.2.2.26, we see that $\lambda^\circ$ induces a pairing of $E_1$-monoidal $\infty$-categories

$$\mu^\circ : \text{Alg}_{E_{k-1}/E_k}(M)^\circ \to \text{Alg}_{E_{k-1}/E_k}(C)^\circ \times_{E_k^\infty} \text{Alg}_{E_{k-1}/E_k}(D)^\circ.$$ 

Applying the inductive hypothesis, we deduce that the underlying pairing $\mu$ is left representable. Assertion (1) implies that the map $M \times_D \{1\} \to C$ is an equivalence of $E_k$-monoidal $\infty$-categories and therefore induces an equivalence

$$\text{Alg}_{E_{k-1}/E_k}(M) \times_{\text{Alg}_{E_{k-1}/E_k}(D)} \{1\} \to \text{Alg}_{E_{k-1}/E_k}(C).$$

Using assumption (2) and Corollary 3.2.2.5, we deduce that $\text{Alg}_{E_{k-1}/E_k}(D)$ admits totalizations of cosimplicial objects. Applying Proposition 5.2.2.27 (and Example 5.1.0.7) to $\mu^\circ$, we deduce that the pairing

$$\text{Alg}_{E_1 \times E_{k-1}/E_k}(M) \to \text{Alg}_{E_1 \times E_{k-1}/E_k}(C) \times_{E_k^\infty} \text{Alg}_{E_1 \times E_{k-1}/E_k}(D))$$

is left representable. The desired result now follows from Theorem 5.1.2.2.

Specializing to the case where $M$ is given by the twisted arrow construction on $C$, we obtain the following:

**Corollary 5.2.3.3.** Let $C$ be an $E_k$-monoidal $\infty$-category. Assume that $C$ admits geometric realizations of simplicial objects and that the unit object $1 \in C$ is final. Then the pairing of $E_k$-monoidal $\infty$-categories

$$\lambda^\circ : \text{TwArr}(C)^\circ \to C^\circ \times_{E_k^\infty}(C^{\text{op}})^\circ$$

of Example 5.2.2.23 induces a left representable pairing

$$\text{Alg}_{E_k}(\lambda) : \text{Alg}_{E_k}(\text{TwArr}(C)) \to \text{Alg}_{E_k}(C) \times \text{Alg}_{E_k}(C^{\text{op}}).$$

**Notation 5.2.3.4.** In the situation of Corollary 5.2.3.3, we will denote the duality functor $D_{\text{Alg}_{E_k}(\lambda)}$ by $\text{Bar}(k) : \text{Alg}_{E_k}(C) \to \text{Alg}_{E_k}(C^{\text{op}})^{\text{op}}$, and refer to it as the $k$-fold bar construction.

**Remark 5.2.3.5.** The inductive strategy used to prove Theorem 5.2.3.1 does not apply directly to Corollary 5.2.3.3, because the intermediate pairings

$$\text{Alg}_{E_{k-1}/E_k}(\text{TwArr}(C)) \to \text{Alg}_{E_{k-1}/E_k}(C) \times \text{Alg}_{E_{k-1}/E_k}(C^{\text{op}})$$

are usually not perfect.

**Remark 5.2.3.6.** Let $C$ be an $E_k$-monoidal $\infty$-category which admits totalizations of cosimplicial objects for which the unit object $1 \in C$ is initial. Then the dual form of Corollary 5.2.3.3 implies that the pairing

$$\text{Alg}_{E_k}(\lambda) : \text{Alg}_{E_k}(\text{TwArr}(C)) \to \text{Alg}_{E_k}(C) \times \text{Alg}_{E_k}(C^{\text{op}})^{\text{op}}$$

is right representable, and therefore induces a duality functor

$$\text{Cobar}^{(n)} : \text{Alg}_{E_k}(C^{\text{op}})^{\text{op}} \to \text{Alg}_{E_k}(C)$$
which we will refer to as the \( k \)-fold cobar construction If \( \mathcal{C} \) admits both totalizations of cosimplicial objects and geometric realizations of simplicial objects and if the unit object of \( \mathcal{C} \) is both initial and final, then the \( k \)-fold bar and cobar construction determine an adjunction

\[
\text{Alg}_{/E_k}(\mathcal{C}) \xrightarrow{\text{Bar}^{(k)}} \text{Alg}_{/E_k}(\mathcal{C}^{\text{op}})^{\text{op}}.
\]

In the situation of Theorem 5.2.3.1, we can remove hypothesis (1) by passing to reduced pairings. Combining Theorem 5.2.3.1 with Proposition 5.2.4.20 and Remark 5.2.4.16, we obtain the following:

**Corollary 5.2.3.7.** Let \( 0 < k < \infty \) and let \( \lambda^\otimes: M^\otimes \to \mathcal{C}^\otimes \times E_k^\otimes \mathcal{D}^\otimes \) be a pairing of \( E_k \)-monoidal \( \infty \)-categories. Assume that the underlying pairing \( \lambda: M \to \mathcal{C} \times \mathcal{D} \) is left representable and that \( \mathcal{D} \) admits totalizations of cosimplicial objects. Then the induced pairing

\[
\text{Alg}_{/E_k}(\lambda^{\text{red}}): \text{Alg}_{/E_k}(M^{\text{red}}) \to \text{Alg}_{/E_k}(\mathcal{C}^{\text{red}}) \times \text{Alg}_{/E_k}(\mathcal{D}^{\text{red}})
\]

is left representable.

**Remark 5.2.3.8.** In the situation of Corollary 5.2.3.7, the forgetful functor \( \text{Alg}_{/E_k}(M^{\text{red}}) \to \text{Alg}_{/E_k}(M) \) is an equivalence of \( \infty \)-categories (Example 5.2.4.18). Consequently, we identify \( E_k \)-algebra objects of \( M \) with triples \((A, B, \eta)\) where \( A \in \text{Alg}_{/E_k}(\mathcal{C}^{\text{red}}) \), \( B \in \text{Alg}_{/E_k}(\mathcal{D}^{\text{red}}) \), and \( \eta: B \to \mathcal{D}_{\text{Alg}_{/E_k}(\lambda^{\text{red}})}(A) \) is a morphism in the \( \infty \)-category \( \text{Alg}_{/E_k}(\mathcal{D}^{\text{red}}) \).

**Example 5.2.3.9.** Let \( \mathcal{C} \) be an \( E_k \)-monoidal \( \infty \)-category with a unit object \( 1 \). We will regard \( 1 \) as a trivial algebra object of both \( \mathcal{C} \) and \( \mathcal{C}^{\text{op}} \), and we define

\[
\text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}) = \text{Alg}_{/E_k}(\mathcal{C})/1, \quad \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}^{\text{op}}) = \text{Alg}_{/E_k}(\mathcal{C}^{\text{op}})/1,
\]

so that \( \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}) \) and \( \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}^{\text{op}}) \) are equivalent to the \( \infty \)-categories of \( E_k \)-algebra objects of \( \mathcal{C}_{1/1} \) and \( \mathcal{C}_{1/1}^{\text{op}} \), respectively. Applying the construction of Example 5.2.4.18 to the pairing of \( E_k \)-monoidal \( \infty \)-categories

\[
\lambda^\otimes: \text{TwArr}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \times E_k^\otimes (\mathcal{C}^{\text{op}})^\otimes,
\]

we obtain the reduced pairing

\[
\text{TwArr}(\mathcal{C}_{1/1}) \to \mathcal{C}_{1/1} \times \mathcal{C}_{1/1}^{\text{op}}
\]

(see Example 5.2.4.17). Passing to algebra objects, we obtain a diagram

\[
\text{Alg}_{/E_k}((\text{TwArr}(\mathcal{C}_{1/1})) \simeq \text{Alg}_{/E_k}((\text{TwArr}(\mathcal{C}_{1/1})) \to \text{Alg}_{/E_k}(\mathcal{C}_{1/1}) \times \text{Alg}_{/E_k}(\mathcal{C}_{1/1}^{\text{op}}) \simeq \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}) \times \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}^{\text{op}})
\]

where second map is a pairing of \( \infty \)-categories. Using Corollary 5.2.3.7, we see that this pairing is left representable if \( \mathcal{C} \) admits geometric realizations of simplicial objects and right representable if \( \mathcal{C} \) admits totalizations of cosimplicial objects. We will denote the associated duality functors (if they exist) by

\[
\text{Bar}^{(k)}: \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C})^{\text{op}} \to \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}^{\text{op}}),
\]

\[
\text{Cobar}^{(k)}: \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C}^{\text{op}}) \to \text{Alg}^{\text{aug}}_{/E_k}(\mathcal{C})^{\text{op}}.
\]

In good cases, one can obtain the \( k \)-fold bar construction \( \text{Bar}^{(k)} \) as a \( k \)-fold composition of ordinary bar constructions. To see this, we first need a remark on the functoriality of Theorem 5.2.3.1:
Proposition 5.2.3.10. Let \(0 < k < \infty\) and suppose we are given pairings of \(\mathbb{E}_k\)-monoidal \(\infty\)-categories \(\lambda : \mathcal{M} \to \mathcal{E} \otimes \mathbb{E}_k \mathcal{D}\) \(\lambda' : \mathcal{M}' \to \mathcal{E}' \otimes \mathbb{E}_k \mathcal{D}'\).

Let \(\alpha : \mathcal{E} \to \mathcal{E}'\), \(\beta : \mathcal{D} \to \mathcal{D}'\) and \(\gamma : \mathcal{M} \to \mathcal{M}'\) be lax \(\mathbb{E}_k\)-monoidal functors which fit into a commutative diagram

\[
\begin{array}{ccc}
\mathcal{M} & \xrightarrow{\gamma} & \mathcal{M}' \\
\downarrow{\lambda} & & \downarrow{\lambda'} \\
\mathcal{E} \otimes \mathbb{E}_k \mathcal{D} & \xrightarrow{\alpha \times \beta} & \mathcal{E}' \otimes \mathbb{E}_k \mathcal{D}'
\end{array}
\]

commutative. Assume that:

1. If \(1_D\) and \(1_{D'}\) are the unit objects of \(\mathcal{D}\) and \(\mathcal{D}'\), respectively, then the right fibrations \(\mathcal{M} \times_D \{1_D\} \to \mathcal{C}\) and \(\mathcal{M}' \times_{D'} \{1_{D'}\} \to \mathcal{C}'\) are trivial Kan fibrations.

2. The pairings \(\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}\) and \(\lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}'\) are left representable.

3. The \(\infty\)-categories \(\mathcal{D}\) and \(\mathcal{D}'\) admit totalizations of cosimplicial objects.

4. The lax \(\mathbb{E}_k\)-monoidal functor \(\alpha\) is monoidal and \(\beta\) preserves unit objects.

5. The underlying functor \(\mathcal{D} \to \mathcal{D}'\) preserves totalizations of cosimplicial objects.

6. The underlying morphism of pairings

\[
\begin{array}{ccc}
\mathcal{M} & \xrightarrow{\lambda} & \mathcal{M}' \\
\downarrow{\lambda} & & \downarrow{\lambda'} \\
\mathcal{E} \times \mathcal{D} & \xrightarrow{\alpha \times \beta} & \mathcal{E}' \times \mathcal{D}'
\end{array}
\]

is left representable: that is, \(\gamma\) carries left universal objects of \(\mathcal{M}\) to left universal objects of \(\mathcal{M}'\). Then the induced morphism of pairings

\[
\begin{array}{ccc}
\Alg_{/\mathbb{E}_k}(\mathcal{M}) & \xrightarrow{\Alg_{/\mathbb{E}_k}(\lambda)} & \Alg_{/\mathbb{E}_k}(\mathcal{M}') \\
\Alg_{/\mathbb{E}_k}(\mathcal{E}) \times \Alg_{/\mathbb{E}_k}(\mathcal{D}) & \xrightarrow{\Alg_{/\mathbb{E}_k}(\lambda') \times \Alg_{/\mathbb{E}_k}(\lambda)} & \Alg_{/\mathbb{E}_k}(\mathcal{E}') \times \Alg_{/\mathbb{E}_k}(\mathcal{D}')
\end{array}
\]

is left representable. In particular, the diagram

\[
\begin{array}{ccc}
\Alg_{/\mathbb{E}_k}(\mathcal{E})^{op} & \xrightarrow{\Alg_{/\mathbb{E}_k}(\mathcal{E})^{op}} & \Alg_{/\mathbb{E}_k}(\mathcal{E}')^{op} \\
\Alg_{/\mathbb{E}_k}(\mathcal{D}) \xrightarrow{\Alg_{/\mathbb{E}_k}(\lambda') \times \Alg_{/\mathbb{E}_k}(\lambda)} & \Alg_{/\mathbb{E}_k}(\mathcal{D}')
\end{array}
\]

commutes up to canonical homotopy (see Proposition 5.2.1.17).
Example 5.2.3.11. Let \( f^\otimes : \mathcal{C}^\otimes \to \mathcal{C'}^\otimes \) be an \( \mathbb{E}_k \)-monoidal functor between \( \mathbb{E}_k \)-monoidal \( \infty \)-categories. Assume that the underlying \( \infty \)-categories \( \mathcal{C} \) and \( \mathcal{C}' \) admit geometric realizations, that the underlying functor \( \mathcal{C} \to \mathcal{C}' \) preserves geometric realizations, and that the unit objects of \( \mathcal{C} \) and \( \mathcal{C}' \) are final. Then \( f^\otimes \) induces a morphism between pairings of monoidal \( \infty \)-categories

\[
\begin{array}{ccc}
\text{TwArr}(\mathcal{C})^\otimes & \xrightarrow{\lambda^\otimes} & \text{TwArr}(\mathcal{C}')^\otimes \\
\downarrow & & \downarrow \\
\mathcal{C}^\otimes \times \mathbb{E}_k^\otimes (\mathcal{C}')^\otimes & \xrightarrow{\lambda'^\otimes} & \mathcal{C}'^\otimes \times \mathbb{E}_k^\otimes (\mathcal{C}')^\otimes
\end{array}
\]

and therefore a morphism of pairings

\[
\begin{array}{ccc}
\text{Alg}_{/\mathbb{E}_k}(\text{TwArr}(\mathcal{C})) & \xrightarrow{\text{Alg}_{/\mathbb{E}_k}(\lambda)} & \text{Alg}_{/\mathbb{E}_k}(\text{TwArr}(\mathcal{C}')) \\
\downarrow & & \downarrow \\
\text{Alg}_{/\mathbb{E}_k}(\mathcal{C}) \times \text{Alg}_{/\mathbb{E}_k}(\mathcal{C})^\text{op} & \xrightarrow{\text{Alg}_{/\mathbb{E}_k}(\lambda')} & \text{Alg}_{/\mathbb{E}_k}(\mathcal{C}') \times \text{Alg}_{/\mathbb{E}_k}(\mathcal{C}')^\text{op}.
\end{array}
\]

Theorem 5.2.2.17 shows that the pairings \( \text{Alg}_{/\mathbb{E}_k}(\lambda) \) and \( \text{Alg}_{/\mathbb{E}_k}(\lambda') \) are left representable, and Proposition 5.2.3.10 shows that the functor \( \text{Alg}_{/\mathbb{E}_k}(\text{TwArr}(\mathcal{C})) \to \text{Alg}_{/\mathbb{E}_k}(\text{TwArr}(\mathcal{C}')) \) preserves left universal objects. Using Proposition 5.2.1.17 we see that the diagram

\[
\begin{array}{ccc}
\text{Alg}(\mathcal{C})^\text{op} & \xrightarrow{\text{Bar}^{(k)}} & \text{Alg}(\mathcal{C}')^\text{op} \\
\downarrow & & \downarrow \\
\text{Alg}(\mathcal{C}')^\text{op} & \xrightarrow{\text{Bar}^{(k)}} & \text{Alg}(\mathcal{C}')^\text{op}
\end{array}
\]

commutes up to canonical homotopy.

If we assume that \( \mathcal{C} \) and \( \mathcal{C}' \) admit totalizations of cosimplicial objects, that the underlying functor \( \mathcal{C} \to \mathcal{C}' \) preserves totalizations of cosimplicial objects, and that the unit objects of \( \mathcal{C} \) and \( \mathcal{C}' \) are initial, then the same arguments show that the diagram

\[
\begin{array}{ccc}
\text{Alg}_{/\mathbb{E}_k}(\mathcal{C})^\text{op} & \xrightarrow{\text{Cobar}^{(k)}} & \text{Alg}_{/\mathbb{E}_k}(\mathcal{C})^\text{op} \\
\downarrow & & \downarrow \\
\text{Alg}_{/\mathbb{E}_k}(\mathcal{C}')^\text{op} & \xrightarrow{\text{Cobar}^{(k)}} & \text{Alg}_{/\mathbb{E}_k}(\mathcal{C}')^\text{op}
\end{array}
\]

commutes up to canonical homotopy.

Example 5.2.3.12. Let \( 0 < k, k' < \infty \) and let \( \mathcal{C} \) be an \( \mathbb{E}_{k+k'} \)-monoidal \( \infty \)-category. Suppose that \( \mathcal{C} \) admits geometric realizations of simplicial objects, that the unit object of \( \mathcal{C} \) is final, and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects. It follows that \( \text{Alg}_{/\mathbb{E}_{k+k'}}(\mathcal{C}) \) admits geometric realizations of simplicial objects and that the forgetful functor \( \text{Alg}_{/\mathbb{E}_{k+k'}}(\mathcal{C}) \to \text{Alg}_{/\mathbb{E}_{k'}}(\mathcal{C}^\text{op}) \) preserves geometric realizations of simplicial objects (Proposition 3.2.3.1). Applying Example 5.2.3.11, we conclude that \( \theta \) is compatible with \( k' \)-fold bar constructions: that is, the diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\text{Alg}_{/\mathbb{E}_{k'}}(\text{Alg}_{/\mathbb{E}_{k+k'}}(\mathcal{C})^\text{op}) & \xrightarrow{\text{Bar}^{(k')}} & \text{Alg}_{/\mathbb{E}_{k'}}(\text{Alg}_{/\mathbb{E}_{k+k'}}(\mathcal{C})^\text{op}) \\
\downarrow & & \downarrow \\
\text{Alg}_{/\mathbb{E}_{k'}}(\mathcal{C})^\text{op} & \xrightarrow{\text{Bar}^{(k')}} & \text{Alg}_{/\mathbb{E}_{k'}}(\mathcal{C})^\text{op}
\end{array}
\]
commutes up to canonical homotopy.

We can summarize the situation informally as follows: if \( A \in \text{Alg}_{/E_{k+k'}}(\mathcal{C}) \simeq \text{Alg}_{/E_{k'}}(\text{Alg}_{E_{k+k'}}(\mathcal{C})) \) is an \( E_{k+k'} \)-algebra object of \( \mathcal{C} \) and \( \text{Bar}^{(k')}(A) \) denotes the \( E_k \)-algebra object of \( \mathcal{C}^{\op} \) obtained by applying the bar construction to the underlying \( E_{k'} \)-algebra of \( A \), then \( \text{Bar}^{(k')}(A) \) can be regarded \( E_{k'} \)-coalgebra object of \( \text{Alg}_{E_{k+k'}}(\mathcal{C}) \).

**Example 5.2.3.13.** Let \( 0 < k < \infty \) and let \( \lambda^\otimes : \mathcal{M}^\otimes \to \mathcal{C}^\otimes \otimes_{
abla} E_k \) be a pairing of \( E_k \)-monoidal \( \infty \)-categories. Assume that the underlying pairing \( \lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D} \) is left representable, and consider the diagram \( \sigma : \)

\[
\begin{array}{c}
\text{TwArr}(\mathcal{C})^\otimes \\
\downarrow \mu^\otimes \\
\mathcal{C}^\otimes \times_{\text{Ass}^\otimes (\mathcal{C}^{\op})^\otimes} \mathcal{C}^{\otimes} \times_{\text{Ass}^\otimes} \mathcal{D}^\otimes
\end{array}
\]

given in Variant 5.2.2.24. The underlying map of pairings

\[
\begin{array}{c}
\text{TwArr}(\mathcal{C}) \\
\downarrow \mu \\
\mathcal{C} \times \mathcal{C}^{\op} \\
\downarrow \lambda \\
\mathcal{C} \times \mathcal{D}
\end{array}
\]

is left representable by construction. Assume that the following further conditions are satisfied:

(i) The \( \infty \)-category \( \mathcal{C} \) admits geometric realizations of simplicial objects.

(ii) The \( \infty \)-category \( \mathcal{D} \) admits totalizations of cosimplicial objects.

(iii) The duality functor \( \mathcal{D}_\lambda : \mathcal{C}^{\op} \to \mathcal{D} \) preserves totalizations of cosimplicial objects (this condition is automatic if \( \lambda \) is also right representable).

(iv) Let \( \mathbf{1}_\mathcal{C} \) and \( \mathbf{1}_\mathcal{D} \) be the unit objects of \( \mathcal{C} \) and \( \mathcal{D} \), respectively. Then \( \mathbf{1}_\mathcal{C} \) and \( \mathbf{1}_\mathcal{D} \) are final objects of \( \mathcal{C} \) and \( \mathcal{D} \), and the right fibrations \( \mathcal{M} \times \mathcal{C} \{ \mathbf{1}_\mathcal{C} \} \to \mathcal{D} \) and \( \mathcal{M} \times \mathcal{D} \{ \mathbf{1}_\mathcal{D} \} \to \mathcal{C} \) are categorical equivalences.

It follows from (iv) that the duality functor \( \mathcal{D}_\lambda \) carries the unit object of \( \mathcal{C} \) to the unit object of \( \mathcal{D} \), so that the hypotheses of Proposition 5.2.3.10 are satisfied. We conclude that the morphism of pairings

\[
\begin{array}{c}
\text{Alg}_{/E_k}(\text{TwArr}(\mathcal{C})) \\
\downarrow \text{Alg}_{/E_k}(\mu) \\
\text{Alg}_{/E_k}(\mathcal{C}) \times \text{Alg}_{/E_k}(\mathcal{C}^{\op}) \\
\downarrow \text{Alg}_{/E_k}(\lambda) \\
\text{Alg}_{/E_k}(\mathcal{C}) \times \text{Alg}_{/E_k}(\mathcal{D})
\end{array}
\]

is left representable. In particular, the duality functor \( \mathcal{D}_{\text{Alg}_{/E_k}(\lambda)} : \text{Alg}_{/E_k}(\mathcal{C})^{\op} \to \text{Alg}_{/E_k}(\mathcal{D}) \) is given by the composition

\[
\text{Alg}_{/E_k}(\mathcal{C})^{\op} \xrightarrow{\text{Bar}^{(k)}} \text{Alg}_{/E_k}(\mathcal{C}^{\op}) \xrightarrow{\phi} \text{Alg}_{/E_k}(\mathcal{D})
\]

where \( \text{Bar}^{(k)} \) denotes the \( k \)-fold bar construction and \( \phi \) is given by composition with the lax \( E_k \)-monoidal functor \( (\mathcal{C}^{\op})^\otimes \to \mathcal{D}^\otimes \) of Remark 5.2.2.25 (given on objects \( C \to \mathcal{D}_\lambda(C) \)).

**Example 5.2.3.14.** Let \( 0 < k, k' < \infty \) and let \( \mathcal{C} \) be an \( E_{k+k'} \)-monoidal \( \infty \)-category. Assume that \( \mathcal{C} \) admits geometric realizations of simplicial objects, that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric
realizations of simplicial objects, and that the unit object of \( \mathcal{C} \) is final. Then the \( k \)-fold bar construction determines a lax \( \mathbb{E}_k \)-monoidal functor from \( \text{Alg}_{\mathbb{E}_k}/(\mathbb{E}_k)^{op} \) to \( \text{Alg}_{\mathbb{E}_k}/(\mathbb{E}_k)^{op} \) (Remark 5.2.2.25). Applying Example 5.2.3.13, we see that the \( (k + k') \)-fold bar construction is given by the composition

\[
\text{Alg}_{/\mathbb{E}_{k+k'}}(\mathbb{C})^{op} \xrightarrow{\text{Bar}^{(k')}} \text{Alg}_{/\mathbb{E}_{k'}}(\text{Alg}_{\mathbb{E}_k}/(\mathbb{E}_k)^{op})^{op} \xrightarrow{\text{Bar}^{(k)}} \text{Alg}_{/\mathbb{E}_{k'}}(\text{Alg}_{\mathbb{E}_k}/(\mathbb{E}_k)^{op})^{op}
\]

Here \( \text{Bar}^{(k')} \) indicates the \( k' \)-fold bar construction associated to the \( \mathbb{E}_k \)-monoidal \( \infty \)-category \( \text{Alg}_{\mathbb{E}_k}/(\mathbb{E}_k)^{op} \), which is compatible with the \( k \)-fold bar construction on \( \mathcal{C} \) by virtue of Example 5.2.3.12.

**Proof of Proposition 5.2.3.10.** As in the proof of Theorem 5.2.3.1, we will proceed by induction on \( k \). Assume first that \( k > 1 \). Passing to \( \mathbb{E}_{k-1} \)-algebras, we obtain a diagram of \( \mathbb{E}_1 \)-monoidal pairings

\[
\begin{align*}
\text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\mathcal{M})^\otimes & \longrightarrow \text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\mathcal{M}')^\otimes \\
\downarrow\text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\gamma)^\otimes & \downarrow\text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\lambda)^\otimes \\
\text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\mathcal{E})^\otimes \times_{\mathbb{E}_1^\otimes} \text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\mathcal{D})^\otimes & \longrightarrow \text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\mathcal{E}')^\otimes \times_{\mathbb{E}_1^\otimes} \text{Alg}_{\mathbb{E}_{k-1}/\mathbb{E}_k}(\mathcal{D}')^\otimes.
\end{align*}
\]

By virtue of Theorem 5.1.2.2 and the inductive hypothesis, it will suffice to show that this diagram satisfies the hypotheses of Proposition 5.2.3.10. Assumptions (1), (2), and (4) follow immediately from the corresponding assumptions on our original morphism of pairings, (3) and (5) follow from Corollary 3.2.2.5, and assumption (6) follows from the inductive hypothesis.

It remains to treat the case \( k = 1 \). In what follows, we will indulge a slight abuse of notation by identifying \( \mathbb{E}_1^\otimes \) with the associative \( \infty \)-operad and work with monoidal \( \infty \)-categories throughout. We wish to show that the functor \( \text{Alg}(\mathcal{M}) \to \text{Alg}(\mathcal{M}') \) determined by \( \gamma \) carries left universal objects to left universal objects. Fix \( A \in \text{Alg}(\mathcal{E}) \), and let \( B \in \text{Alg}(\mathcal{D}) \) be a trivial algebra so that (by virtue of assumption (1)) the pair \((A, B)\) can be lifted to an object \( M \in \text{Alg}(\mathcal{M}) \) in an essentially unique way. Let \( A' \in \text{Alg}(\mathcal{E}') \), \( B' \in \text{Alg}(\mathcal{D}') \), and \( M' \in \text{Alg}(\mathcal{M}') \) be the images of \( A \), \( B \), and \( M \); condition (4) guarantees that \( B' \) is a trivial algebra object of \( \mathcal{D}' \). Using Propositions 5.2.2.28 and 5.2.2.30, we see that it suffices to show that the induced functor \( 
abla \text{BMod}_M(\mathcal{M}) \to 
abla \text{BMod}_{M'}(\mathcal{M}') \) preserves left universal objects. In other words, we must show that for \( C \in \text{AMod}_\mathcal{A}(\mathcal{E}) \) having image \( C' \in \text{AMod}_\mathcal{A}(\mathcal{E}') \), the canonical map \( u_C : \beta(\nabla \mathcal{M}(C)) \to \nabla \mathcal{M}'(C') \) is an equivalence in \( \mathcal{D}' \). Let \( \theta : \text{AMod}_\mathcal{A}(\mathcal{E}) \to \mathcal{C} \) be the forgetful functor and choose a \( \theta \)-split simplicial object \( C' \) with \( C \simeq [C] \) such that each \( C_n \) belongs to the essential image of the left adjoint of \( \theta \). Let \( C'_n \) be the image of \( C_n \) in \( \text{AMod}_\mathcal{A}(\mathcal{E}') \) and let \( \theta' : \text{AMod}_\mathcal{A}(\mathcal{E}') \to \mathcal{C}' \) be the forgetful functor. The simplicial object \( \theta'(C'_n) = \alpha(\theta(C)) \) is split with colimit \( \theta'(C') \simeq \alpha(\theta(C)) \). It follows from Variant 4.7.3.6 that the canonical map \( [C] \to C' \) is an equivalence. Moreover, assumption (4) implies that each \( C_n \) lies in the essential image of the left adjoint to \( \theta' \). Arguing as in proof of Lemma 5.2.2.38, we conclude that the maps

\[
\mathcal{D}_\mathcal{M} C \to \lim \mathcal{D}_\mathcal{M} C_n \quad \mathcal{D}_{\mathcal{M}'} C' \to \lim \mathcal{D}_{\mathcal{M}'} C'_n
\]

are equivalences. Combining this with (5), we conclude that \( u_C \) is the totalization of the diagram \( [n] \to u_{C_n} \). It will therefore suffice to prove that \( u_{C_n} \) is an equivalence for each \( n \geq 0 \). We may therefore replace \( C \) by \( C_n \) and thereby reduce to the case where \( C = \phi(\mathcal{C}) \), where \( \phi : \mathcal{C} \to \text{AMod}_\mathcal{A}(\mathcal{E}) \) is a left adjoint to \( \theta \). Let \( \phi', \phi : \mathcal{C}' \to \text{AMod}_\mathcal{A}(\mathcal{E}') \) be a left adjoint to \( \theta' \), so that condition (4) implies that \( C' \simeq \phi'(\mathcal{C}') \) where \( \mathcal{C}' = \alpha(\mathcal{C}) \). Using Lemma 5.2.2.32, we are reduced to showing that the induced map \( \beta(\mathcal{M}(\mathcal{C}')) \to \mathcal{M}(\mathcal{C}') \) is an equivalence, which follows immediately from (6).

We conclude this section by establishing a generalization of Corollary 5.2.2.13, which describes the result of applying an iterated bar construction to a free algebra.
**Proposition 5.2.3.15.** Let $0 < k < \infty$ and let $\mathcal{C}$ be an $\mathbb{E}_k$-monoidal $\infty$-category. Assume that:

(a) The initial object of $\mathcal{C}$ is both initial and final.

(b) For every countable weakly contractible simplicial set $K$, the $\infty$-category $\mathcal{C}$ admits $K$-indexed colimits.

(c) For every countable weakly contractible simplicial set $K$, the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves $K$-indexed colimits separately in each variable.

Then:

1. The forgetful functor $\text{Alg}_{/\mathbb{E}_k}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint $\text{Free} : \mathcal{C} \to \text{Alg}_{/\mathbb{E}_k}(\mathcal{C})$.

2. The composite functor

$$\mathcal{C} \xrightarrow{\text{Free}} \text{Alg}_{/\mathbb{E}_k}(\mathcal{C}) \xrightarrow{\text{Bar}^{(k)}} \text{Alg}_{/\mathbb{E}_k}(\mathcal{C}^{op})^{op} \to \mathcal{C}$$

is equivalent to the iterated suspension functor $C \mapsto \Sigma^k C$.

**Proof.** If $k = 1$, the desired result follows from Corollary 5.2.2.13 (see Remark 5.2.2.14). We will handle the general case using induction on $k$. Assume that $k > 1$ and set $D = \text{Alg}_{/\mathbb{E}_{k-1}/\mathbb{E}_k}(\mathcal{C})$. Then $D$ inherits the structure of a monoidal $\infty$-category and Theorem 5.1.2.2 allows us to identify $\text{Alg}_{/\mathbb{E}_k}(\mathcal{C})$ with the $\infty$-category $\text{Alg}(D)$. We first observe that $D$ satisfies conditions (a), (b), and (c) (see Proposition 5.1.2.9). By the inductive hypothesis, the forgetful functors $D \to \mathcal{C}$, $\text{Alg}(D) \to D$ admit left adjoints which we will denote by $\text{Free}'$ and $\text{Free}''$, so that the forgetful functor $\text{Alg}_{/\mathbb{E}_k}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint given by the composition $\text{Free}'' \circ \text{Free}'$. Let us abuse notation by viewing $\text{Bar}^{(k)}$ as a functor from $\text{Alg}_{/\mathbb{E}_k}(\mathcal{C})$ to $\mathcal{C}$; using Example 5.2.3.14 we can identify $\text{Bar}^{(k)}$ with the composition

$$\text{Alg}(D) \xrightarrow{\text{Bar}^{(1)}} D = \text{Alg}_{/\mathbb{E}_{k-1}}(\mathcal{C}) \xrightarrow{\text{Bar}^{(k-1)}} \mathcal{C}.$$ 

Using the inductive hypothesis, we compute

$$\text{Bar}^{(k)} \circ \text{Free} \simeq \text{Bar}^{(k-1)} \circ \text{Bar}^{(1)} \circ \text{Free}'' \circ \text{Free}' \simeq \text{Bar}^{(k-1)} \circ \Sigma_D \circ \text{Free}' \simeq \text{Bar}^{(k-1)} \circ \text{Free}' \circ \Sigma \simeq \Sigma^{k-1} \circ \Sigma = \Sigma^k,$$

where $\Sigma_D$ denotes the suspension functor on the $\infty$-category $D$, and the third equivalence follows from the fact that the functor $\text{Free}'$ commutes with suspension by virtue of being a left adjoint.

**5.2.4 Reduced Pairings**

Let

$$\lambda : \mathcal{M} \to \mathcal{C} \times_{\text{Ass}} \mathcal{D}$$

be a pairing of monoidal $\infty$-categories. Proposition 5.2.2.27 supplies sufficient conditions for the induced pairing

$$\text{Alg}(\lambda) : \text{Alg}(\mathcal{M}) \to \text{Alg}(\mathcal{C}) \times \text{Alg}(\mathcal{D})$$

to be left (or right) representable. However, there are many naturally arising pairings which do not satisfy the hypotheses of Proposition 5.2.2.27. The main culprit is condition (1), which requires that the right fibration

$$\theta : \mathcal{M} \times_{\mathcal{D}} \{1\} \to \mathcal{C}$$
be a categorical equivalence. Note that if \( \mathcal{C} \) is a monoidal \( \infty \)-category and \( \lambda^\otimes \) is the canonical pairing 
\( \text{TwArr}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \times_{\text{Ass}^\otimes} (\mathcal{C}^{op})^\otimes, \) then \( \theta \) is an equivalence if and only if the unit object \( 1 \in \mathcal{C} \) is a final object. This condition is often not satisfied, but we can remedy the situation by replacing \( \mathcal{C} \) by the \( \infty \)-category \( \mathcal{C}/1. \)

Our goal in this section is to describe an analogous procedure which can be applied to an arbitrary pairing of monoidal \( \infty \)-categories, not necessarily given by the twisted arrow construction of §5.2.1.

**Definition 5.2.4.1.** Let \( \lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D} \) be a pairing of \( \infty \)-categories. We will say that \( \lambda \) is *reduced* if the following conditions are satisfied:

(a) The \( \infty \)-categories \( \mathcal{C} \) and \( \mathcal{D} \) have initial objects \( 1_\mathcal{C} \) and \( 1_\mathcal{D}. \)

(b) The right fibrations
\[
\mathcal{M} \times \mathcal{D}\{1_\mathcal{D}\} \to \mathcal{C}, \quad \mathcal{M} \times \mathcal{C}\{1_\mathcal{C}\} \to \mathcal{D}
\]
are trivial Kan fibrations.

We will say that \( \lambda \) is *weakly reduced* if the \( \infty \)-category \( \mathcal{M} \) has an initial object \( 1_\mathcal{M} \) whose images in \( \mathcal{C} \) and \( \mathcal{D} \) are also initial.

**Remark 5.2.4.2.** Let \( \lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D} \) be a reduced pairing of \( \infty \)-categories. Then the fiber \( \mathcal{M}_{(1_\mathcal{C},1_\mathcal{D})} \) is a contractible Kan complex. Moreover, any object \( 1_\mathcal{M} \in \mathcal{M}_{(1_\mathcal{C},1_\mathcal{D})} \) is an initial object of \( \mathcal{M} \), so that \( \lambda \) is also weakly reduced.

**Definition 5.2.4.3.** Let \( \lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D} \) and \( \lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}' \) be weakly reduced pairings of \( \infty \)-categories. We will say that a morphism of pairings
\[
\mathcal{M} \xrightarrow{\gamma} \mathcal{M}' \quad \mathcal{C} \times \mathcal{D} \xleftarrow{\alpha \times \beta} \mathcal{C}' \times \mathcal{D}'
\]
is *reduced* if the functor \( \gamma \) preserves initial objects (from which it follows that \( \alpha \) and \( \beta \) also preserve initial objects).

We let \( \text{CPair}^{wred} \) denote the subcategory of \( \text{CPair} \) whose objects are weakly reduced pairings of \( \infty \)-categories and whose morphisms are reduced morphisms. We let \( \text{CPair}^{red} \) denote the full subcategory of \( \text{CPair}^{wred} \) spanned by the reduced pairing of \( \infty \)-categories.

**Example 5.2.4.4.** Let \( \mathcal{C} \) be an \( \infty \)-category containing an initial object \( X \) and a final object \( Y \). Then the \( \infty \)-category \( \text{TwArr}(\mathcal{C}) \) has an initial object, given by any morphism \( f : X \to Y \). Let \( \lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{op} \) be the pairing of \( \infty \)-categories of Proposition 5.2.1.3, so that \( \lambda(f) = (C,D) \). Note that the projection maps
\[
\mathcal{M} \times \{C^{op}\}\{D\} \to \mathcal{C}, \quad \mathcal{M} \times \mathcal{C}\{C\} \to \mathcal{C}^{op}
\]
are right fibrations represented by the objects \( D \in \mathcal{C} \) and \( C \in \mathcal{C}^{op} \), respectively, and are therefore trivial Kan fibrations. It follows that \( \lambda \) is a reduced pairing of \( \infty \)-operads.

**Remark 5.2.4.5.** The \( \infty \)-category \( \text{CPair} \) has a final object, given by the pairing of \( \infty \)-categories \( \lambda_0 : \Delta^0 \to \Delta^0 \times \Delta^0 \). It is clear that the pairing \( \lambda_0 \) is reduced. For any weakly reduced pairing of \( \infty \)-categories \( \lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D} \), the mapping space \( \text{Map}_{\text{CPair}^{wred}}(\lambda_0, \lambda) \) is contractible: that is, there is essentially only one reduced morphism of pairings
\[
\Delta^0 \xrightarrow{\lambda_0} \mathcal{M} \xrightarrow{\lambda} \mathcal{C} \times \mathcal{D}.
\]
for which the horizontal maps determine initial objects of \( M, C, \) and \( D \). It follows that the \( \infty \)-categories \( \text{CPair}^{\text{red}} \) and \( \text{CPair}^{\text{wred}} \) are pointed, so that the forgetful functors
\[
\text{CPair}^{\text{wred}}_* \to \text{CPair}^{\text{wred}} \quad \text{CPair}^{\text{red}}_* \to \text{CPair}^{\text{red}}
\]
are equivalences of \( \infty \)-categories.

**Remark 5.2.4.6.** It follows immediately from the definitions that the inclusions of subcategories
\[
\text{CPair}^{\text{wred}}_* \hookrightarrow \text{CPair}_* \hookleftarrow \text{CPair}^{\text{red}}_*
\]
induce fully faithful embeddings
\[
\text{CPair}^{\text{wred}}_* \hookrightarrow \text{CPair}_* \hookleftarrow \text{CPair}^{\text{red}}_*.\n\]

**Remark 5.2.4.7.** Let \( \lambda : M \to C \times D \) be a pairing of \( \infty \)-categories, given by a pair of functors \( \lambda_C : M \to C \) and \( \lambda_D : M \to D \). Suppose that \( \lambda \) is reduced, so that \( \lambda_C \) induces an equivalence of \( \infty \)-categories
\[
M \times D \{1_D\} \to C.
\]
Let \( f \) be a homotopy inverse to this equivalence. Then, when regarded as a functor from \( C \) to \( M \), \( f \) is left adjoint to \( \lambda_C \). In particular, the functor \( \lambda_C \) admits a left adjoint and is therefore left cofinal.

Our first main result is the following:

**Proposition 5.2.4.8.** The inclusion functor \( \text{CPair}^{\text{red}}_* \hookrightarrow \text{CPair}_* \) admits a right adjoint.

By virtue of Remark 5.2.4.5, Proposition 5.2.4.8 is an immediate consequence of the following pair of results:

**Lemma 5.2.4.9.** The inclusion \( \text{CPair}^{\text{wred}}_* \hookrightarrow \text{CPair}_* \) admits a right adjoint.

**Lemma 5.2.4.10.** The inclusion \( \text{CPair}^{\text{red}}_* \hookrightarrow \text{CPair}^{\text{wred}}_* \) admits a right adjoint.

We will deduce Lemma 5.2.4.9 from the following more basic assertion:

**Lemma 5.2.4.11.** Let \( (\text{Cat}_{\infty})_* \) denote the \( \infty \)-category of pointed objects of \( \text{Cat}_{\infty} \) (that is, the \( \infty \)-category whose objects are \( \infty \)-categories \( C \) with a distinguished object \( C \in C \)) and let \( (\text{Cat}_{\infty})^{\text{wred}}_* \) denote the full subcategory of \( (\text{Cat}_{\infty})_* \), spanned by those objects for which \( C \in C \) is initial. Then the inclusion
\[
(\text{Cat}_{\infty})^{\text{wred}}_* \hookrightarrow (\text{Cat}_{\infty})_*
\]
admits a right adjoint, given on objects by \( (\mathcal{C}, C) \mapsto (\mathcal{C}/_C, \text{id}_C) \).

**Proof.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories with distinguished objects \( C \) and \( D \). We wish to prove that if \( D \in \mathcal{D} \) is initial, then the canonical map
\[
\theta : \text{Map}(\text{Cat}_{\infty}),(\mathcal{D}, D),(\mathcal{C}/_C, \text{id}_C)) \to \text{Map}(\text{Cat}_{\infty}),(\mathcal{D}, D),(\mathcal{C}, C))
\]
is a homotopy equivalence. Unwinding the definitions, we can identify \( \theta \) the restriction to maximal Kan complexes of the functor
\[
\text{Fun}(\mathcal{D}, \mathcal{C}/_C) \times_{\mathcal{C}/_C} \{\text{id}_C\} \to \text{Fun}(\mathcal{D}, \mathcal{C}) \times_{\mathcal{C}} \{C\}.
\]
We claim that this map is a trivial Kan fibration. To prove this, it suffices to show that for every monomorphism of simplicial sets \( K \hookrightarrow L \), every lifting problem
\[
\begin{array}{ccc}
\{D\} \times L \\
\downarrow \downarrow \\
\mathcal{D} \times L \\
\end{array}
\]
admits a solution. Since the right vertical map is a left fibration, it will suffice to show that the right vertical map is left anodyne. By virtue of Lemma T.2.1.2.4, this is automatic if the inclusion \( \{D\} \hookrightarrow \mathcal{D} \) is left anodyne (or equivalently right cofinal; see Proposition T.4.1.1.3). This follows from Theorem T.4.1.3.1, since \( D \) is an initial object of \( \mathcal{D} \).
5.2. BAR CONSTRUCTIONS AND KOSZUL DUALITY

Proof of Lemma 5.2.4.9. Let us identify $\text{CPair}$ with the full subcategory of $\text{Fun}(\Delta^1 \Pi_0 \Delta^1, \text{Cat}_\infty)$ spanned by those diagrams

$$\mathcal{C} \leftarrow M \rightarrow \mathcal{D}$$

for which the induced map $M \rightarrow \mathcal{C} \times \mathcal{D}$ is equivalent to a right fibration. It follows from Lemma 5.2.4.11 that the inclusion

$$\text{Fun}(\Delta^1 \Pi_0 \Delta^1, (\text{Cat}_\infty)_*) \hookrightarrow \text{Fun}(\Delta^1 \Pi_0 \Delta^1, (\text{Cat}_\infty)_*)$$

admits a right adjoint. It will therefore suffice to show that this right adjoint carries the full subcategory $\text{CPair}_* \subseteq \text{Fun}(\Delta^1 \Pi_0 \Delta^1, (\text{Cat}_\infty)_*)$ into $\text{CPair}_wred_* \subseteq \text{Fun}(\Delta^1 \Pi_0 \Delta^1, (\text{Cat}_\infty)_*)$. Unwinding the definitions, we must show that if $\lambda : M \rightarrow \mathcal{C} \times \mathcal{D}$ is a right fibration and we are given an object $1_M$ with having image $\lambda(1_M) = (1_\mathcal{C}, 1_\mathcal{D}) \in \mathcal{C} \times \mathcal{D}$, then the induced map

$$\lambda_* : M_{1_M/} \rightarrow \mathcal{C}_{1_\mathcal{C}/} \times \mathcal{D}_{1_\mathcal{D}/}$$

is also a pairing of $\infty$-categories. This follows immediately from Proposition T.2.1.2.1.

We will prove Lemma 5.2.4.10 by means of an explicit construction.

Construction 5.2.4.12. Let $\lambda : M \rightarrow \mathcal{C} \times \mathcal{D}$ be a weakly reduced pairing of $\infty$-categories. We will identify $\lambda$ with a pair of maps

$$\lambda_\mathcal{C} : M \rightarrow \mathcal{C} \quad \lambda_\mathcal{D} : M \rightarrow \mathcal{D}.$$

We let $\mathcal{C}^*$ denote the full subcategory of $\mathcal{M}$ spanned by those objects $M$ such that $\lambda_\mathcal{D}(M)$ is an initial object of $\mathcal{D}$, and we let $\mathcal{D}^*$ denote the full subcategory of $\mathcal{M}$ spanned by those objects $M$ for which $\lambda_\mathcal{C}(M)$ is an initial object of $\mathcal{C}$. We let $\mathcal{M}^*$ denote the full subcategory of the fiber product

$$\mathcal{C} \times_{\text{Fun}(\Delta^1, \mathcal{C})} \text{Fun}(\Delta^1, M) \times_{\text{Fun}(1, M)} \text{Fun}(\Delta^1, M) \times_{\text{Fun}(\Delta^1, \mathcal{D})} \mathcal{D}$$

whose objects are diagrams

$$\overline{C} \xrightarrow{\alpha} M \xleftarrow{\beta} \overline{D}$$

such that $\lambda_\mathcal{C}(\alpha)$ is a degenerate edge of $\mathcal{C}$, $\lambda_\mathcal{D}(\beta)$ is a degenerate edge of $\mathcal{D}$, $\overline{C}$ belongs to $\mathcal{C}^*$, and $\overline{D}$ belongs to $\mathcal{D}^*$. We have evident forgetful functors

$$\lambda_\mathcal{C}^* : M^* \rightarrow \mathcal{C}^* \quad \lambda_\mathcal{D}^* : M^* \rightarrow \mathcal{D}^*$$

$$\overline{C} \xrightarrow{\alpha} M \xleftarrow{\beta} \overline{D} \mapsto \overline{C} \quad (\overline{C} \xrightarrow{\alpha} M \xleftarrow{\beta} \overline{D}) \mapsto \overline{D}.$$

Let $\lambda^* : M^* \rightarrow \mathcal{C}^* \times \mathcal{D}^*$ denote the product of $\lambda_\mathcal{C}^*$ with $\lambda_\mathcal{D}^*$. By construction, it fits into a commutative diagram

$$\begin{array}{ccc}
M^* & \xrightarrow{\gamma} & M \\
\downarrow{\lambda^*} & & \downarrow{\lambda} \\
\mathcal{C}^* \times \mathcal{D}^* & \xrightarrow{\lambda_\mathcal{C}^* \times \lambda_\mathcal{D}^*} & \mathcal{C} \times \mathcal{D}
\end{array}$$

where the functor $\gamma$ is given by

$$\gamma(\overline{C} \xrightarrow{\alpha} M \xleftarrow{\beta} \overline{D}) = M.$$

Lemma 5.2.4.10 is an immediate consequence of the following:

Lemma 5.2.4.13. Let $\lambda : M \rightarrow \mathcal{C} \times \mathcal{D}$ be a weakly reduced pairing of $\infty$-categories. Then:

(a) The map $\lambda^* : M^* \rightarrow \mathcal{C}^* \times \mathcal{D}^*$ is a pairing of $\infty$-categories.
(b) The natural map $\mathcal{M}^* \to \mathcal{M}$ is a trivial Kan fibration.

c) The pairing $\lambda^*$ is reduced.

d) The canonical map of pairings $\rho : \lambda^* \to \lambda$ is reduced.

e) For any reduced pairing of $\infty$-categories $\lambda' : \mathcal{M}' \to \mathcal{C}' \times \mathcal{D}'$, composition with $\rho$ induces a homotopy equivalence

$$\operatorname{Map}_{\mathcal{C}\mathcal{P}\mathcal{A}ir^{\text{red}}}(\lambda', \lambda^*) \to \operatorname{Map}_{\mathcal{C}\mathcal{P}\mathcal{A}ir^{\text{red}}}(\lambda', \lambda).$$

Proof. Let $\mathcal{C}^\circ$ denote the full subcategory of $\mathcal{C}$ spanned by the initial objects and let $\mathcal{C}^+ \subseteq \operatorname{Fun}(\Delta^1, \mathcal{C})$ be the full subcategory spanned by those maps $f : C \to C'$ where $C$ is initial. We define $\mathcal{D}^0$ and $\mathcal{D}^+$ similarly, and let $K$ denote the horn $\Delta^1 \amalg_{\{1\}} \Delta^1$.

To prove (a), we note that there is a pullback diagram of simplicial sets

$$\begin{array}{ccc}
\mathcal{M}^* & \to & (\mathcal{C}^* \times \mathcal{D}^*) \times_{\mathcal{C} \times \mathcal{D}^0} \mathcal{C} \times \mathcal{D} \\
\downarrow & & \downarrow \\
\operatorname{Fun}(K, \mathcal{M}) & \to & \operatorname{Fun}(K, \mathcal{C} \times \mathcal{D}) \times_{\operatorname{Fun}(\{0\} \amalg \{0\}, \mathcal{C} \times \mathcal{D})} \operatorname{Fun}(\{0\} \amalg \{0\}, \mathcal{M}).
\end{array}$$

Corollary T.2.1.2.9 implies that the bottom horizontal map is a left fibration, so that the upper horizontal map is also a left fibration. We are therefore reduced to proving that the projection map

$$(\mathcal{C}^* \times \mathcal{D}^*) \times_{\mathcal{C} \times \mathcal{D}^0} \mathcal{C} \times \mathcal{D} \to \mathcal{C}^* \times \mathcal{D}^*$$

is a left fibration. In fact, this map is a trivial Kan fibration, since it is obtained by pulling back along the product of the trivial Kan fibrations

$$\mathcal{C}^+ \to \mathcal{C} \times \mathcal{C}^0, \quad \mathcal{D}^+ \to \mathcal{D} \times \mathcal{D}^0.$$
determines an object of $\mathcal{M}$ which is a preimage of $1$ under the trivial Kan fibration $\mathcal{M} \to \mathcal{M}$, and is therefore an initial object of $\mathcal{M}$ which maps to initial objects of $\mathcal{C}$ and $\mathcal{D}$ under the forgetful functors $\lambda_\mathcal{C}$ and $\lambda_\mathcal{D}$. This proves that the pairing $\lambda^*$ is weakly reduced, and that the map of pairings $\rho : \lambda^* \to \lambda$ is reduced. To complete the proof of (c), let $\lambda^*$ denote the contractible Kan complex of initial objects of $\mathcal{M}$ (which is contained in the intersection $\mathcal{C} \cap \mathcal{D}$); we will show that the maps

$$
\theta : \mathcal{M} \times \mathcal{D} \to \mathcal{C} \quad \theta' : \mathcal{M} \times \mathcal{D} \to \mathcal{D}
$$

are trivial Kan fibrations. This is clear, since $\theta$ and $\theta'$ are obtained via base change from the trivial Kan fibrations $e_1$ and $e_0$, respectively.

We now prove (e). For every pair of $\infty$-categories $\mathcal{X}$ and $\mathcal{Y}$ which admit initial objects, let $\text{Fun}^o(\mathcal{X}, \mathcal{Y})$ denote the full subcategory of $\text{Fun}(\mathcal{X}, \mathcal{Y})$ spanned by those functors which preserve initial objects. Suppose that $\lambda' : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ is a reduced pairing of $\infty$-categories; we wish to show that the induced map

$$
\text{Map}_{\text{CPair}^\text{red}}(\lambda', \lambda^*) \to \text{Map}_{\text{CPair}^\text{red}}(\lambda', \lambda)
$$

is a homotopy equivalence. Unwinding the definitions, we see that this map is obtained by passing to the underlying Kan complexes from a functor of $\infty$-categories

$$
\text{Map}^o(\mathcal{M}, \mathcal{M}^\prime) \times \text{Fun}^o(\mathcal{M}, \mathcal{C} \times \mathcal{D}) \to \text{Fun}^o(\mathcal{C}, \mathcal{C}^\prime) \times \text{Fun}^o(\mathcal{D}, \mathcal{D}^\prime)
$$

We claim that this map is an equivalence of $\infty$-categories. Using (b), we are reduced to proving that the diagram of $\infty$-categories

$$
\begin{array}{ccc}
\text{Fun}(\mathcal{C}, \mathcal{C}^\prime) \times \text{Fun}(\mathcal{D}, \mathcal{D}^\prime) & \longrightarrow & \text{Fun}(\mathcal{M}, \mathcal{C} \times \mathcal{D}) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathcal{C}, \mathcal{C}) \times \text{Fun}(\mathcal{D}, \mathcal{D}) & \longrightarrow & \text{Fun}(\mathcal{M}, \mathcal{C} \times \mathcal{D})
\end{array}
$$

is a homotopy pullback square. This diagram factors as a product of squares

$$
\begin{array}{ccc}
\text{Fun}(\mathcal{C}, \mathcal{C}) & \longrightarrow & \text{Fun}(\mathcal{M}, \mathcal{C}) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathcal{C}, \mathcal{C}) & \longrightarrow & \text{Fun}(\mathcal{M}, \mathcal{C})
\end{array}
\quad
\begin{array}{ccc}
\text{Fun}(\mathcal{D}, \mathcal{D}) & \longrightarrow & \text{Fun}(\mathcal{M}, \mathcal{D}) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathcal{D}, \mathcal{D}) & \longrightarrow & \text{Fun}(\mathcal{M}, \mathcal{D})
\end{array}
$$

so it will suffice to show that each of these squares is homotopy Cartesian. This follows from the observation that the maps $\mathcal{C} \to \mathcal{C}$ and $\mathcal{D} \to \mathcal{D}$ are right fibrations, since the projection maps $\mathcal{M} \to \mathcal{C}$ and $\mathcal{M} \to \mathcal{D}$ are left cofinal by virtue of Remark 5.2.4.7.

**Notation 5.2.4.14.** Let $\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ be an arbitrary pairing of $\infty$-categories, and let $1_{\mathcal{M}} \in \mathcal{M}$ be a distinguished object having image $(1_{\mathcal{C}}, 1_{\mathcal{D}}) \in \mathcal{C} \times \mathcal{D}$ under the map $\lambda$. We let

$$
\lambda^\text{red} : \mathcal{M}^\text{red} \to \mathcal{C}^\text{red} \times \mathcal{D}^\text{red}
$$

be the reduced pairing of $\infty$-categories obtained from the pair $(\lambda, 1_{\mathcal{M}})$ by applying a right adjoint to the inclusion $\text{CPair}^\text{red} \to \text{CPair}$. Our proof of Proposition 5.2.4.8 shows that $\lambda^\text{red}$ can be realized concretely by the map

$$
\mathcal{M}_{1_{\mathcal{M}}}^* \to \mathcal{C}_{1_{\mathcal{C}}}^* \times \mathcal{D}_{1_{\mathcal{D}}}^*.
$$
Remark 5.2.4.15. In the situation of Notation 5.2.4.14, we have canonical equivalences

\[ \mathcal{C}^{\text{red}} \simeq M_{1民} / \times \mathcal{D}_{1民} / \{1\民\} \quad \mathcal{M}^{\text{red}} \simeq M_{1民} / \quad \mathcal{D}^{\text{red}} \simeq M_{1民} / \times \mathcal{E}_{1民} / \{1\民\} \].

Remark 5.2.4.16. In the situation of Notation 5.2.4.14, the forgetful functor \( \mathcal{C}^{\text{red}} \to \mathcal{C} \) can be identified with the composition of the right fibration \( M_{1民} / \times \mathcal{D}_{1民} / \{1\民\} \to \mathcal{E}_{1民} / \) with the left fibration \( \mathcal{E}_{1民} / \to \mathcal{C} \). Let \( K \) be any weakly contractible simplicial set. Combining Propositions T.1.2.13.8 and T.4.4.2.9, we deduce the following:

(*) If \( \mathcal{C} \) admits \( K \)-indexed limits, then the \( \infty \)-category \( \mathcal{C}^{\text{red}} \) admits \( K \)-indexed limits and the forgetful functor \( \mathcal{C}^{\text{red}} \to \mathcal{C} \) preserves \( K \)-indexed limits.

In particular, if \( \mathcal{C} \) admits totalizations of cosimplicial objects, then \( \mathcal{C}^{\text{red}} \) has the same property.

Example 5.2.4.17. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( \lambda : \text{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{op}} \) be the pairing of Proposition 5.2.1.3. Let \( f : C \to D \) be a morphism in \( \mathcal{C} \), so that the \( \infty \)-category \( \mathcal{C}_{C/D} \) has both initial and final objects. Using Example 5.2.4.4, we see that the pairing

\[ \lambda' : \text{TwArr}(\mathcal{C}_{C/D}) \to \mathcal{C}_{C/D} \times \mathcal{C}^{\text{op}}_{C/D} \]

is reduced. It follows that the evident morphism of pairings

\[ \begin{array}{ccc} \text{TwArr}(\mathcal{C}_{C/D}) & \longrightarrow & \text{TwArr}(\mathcal{C}) \\ \downarrow \lambda' & & \downarrow \lambda \\ \mathcal{C}_{C/D} \times \mathcal{C}^{\text{op}}_{C/D} & \longrightarrow & \mathcal{C} \times \mathcal{C}^{\text{op}} \end{array} \]

Using the identification \( \text{TwArr}(\mathcal{C}_{C/D}) \simeq \text{TwArr}(\mathcal{C})_{f/} \) and the description of \( \lambda^{\text{red}} \) given in Remark 5.2.4.15, we see that this morphism of pairings determines an equivalence \( \lambda' \simeq \lambda^{\text{red}} \): that is, it exhibits \( \lambda' \) as universal among reduced pairings with a map to \( \lambda \) in the \( \infty \)-category \( \text{CPair}_* \) (here we regard \( \lambda \) as an object of \( \text{CPair}_* \) via the choice of object \( f \in \text{TwArr}(\mathcal{C}) \)).

Example 5.2.4.18. Let \( G : \text{CPair}_* \to \text{CPair}^{\text{red}}_* \simeq \text{CPair}^{\text{red}} \) be a right adjoint to the inclusion. Since the collection of reduced pairings of \( \infty \)-categories is closed under Cartesian products, we see that \( G \) preserves products when regarded as a functor from \( \text{CPair}_* \) to itself.

Let \( \mathcal{O}^{\circ} \) be an \( \infty \)-operad and let

\[ \lambda^{\circ} : \mathcal{M}^{\circ} \to \mathcal{C}^{\circ} \times \mathcal{O}^{\circ} \mathcal{D}^{\circ} \]

be a pairing of \( \mathcal{O} \)-monoidal \( \infty \)-categories, which we can identify with a \( \mathcal{O} \)-monoid object of \( \text{CPair} \). Assume that the \( \infty \)-operad \( \mathcal{O}^{\circ} \) is unital, so that the forgetful functor \( \text{Mon}_\mathcal{O}(\text{CPair}_*) \to \text{Mon}_\mathcal{O}(\text{CPair}) \) is an equivalence of \( \infty \)-categories. Then \( G \) induces a map

\[ \text{Mon}_\mathcal{O}(\text{CPair}) \simeq \text{Mon}_\mathcal{O}(\text{CPair}_*) \overset{G}{\to} \text{Mon}_\mathcal{O}(\text{CPair}^{\text{red}}) \subseteq \text{Mon}_\mathcal{O}(\text{CPair}) \]

which can be regarded as a right adjoint to the inclusion \( \text{Mon}_\mathcal{O}(\text{CPair}^{\text{red}}) \hookrightarrow \text{Mon}_\mathcal{O}(\text{CPair}) \). Applying this functor to \( \lambda^{\circ} \), we obtain another pairing of \( \mathcal{O} \)-monoidal \( \infty \)-categories

\[ (\lambda^{\text{red}})^{\circ} : (\mathcal{M}^{\text{red}})^{\circ} \to (\mathcal{E}^{\text{red}})^{\circ} \times (\mathcal{D}^{\text{red}})^{\circ} \]

which reduces to the construction of Notation 5.2.4.14 after passing to the fiber over any object \( X \in \mathcal{O} \) (where the distinguished object of the fiber \( \mathcal{M}_X \) is given by the unit with respect to the \( \mathcal{O} \)-monoidal structure).
Remark 5.2.4.19. In the situation of Example 5.2.4.18, the pairing
\[ \text{Alg}_{/ \mathcal{O}}(\lambda) : \text{Alg}_{/ \mathcal{O}}(\mathcal{M}) \to \text{Alg}_{/ \mathcal{O}}(\mathcal{E}) \times \text{Alg}_{/ \mathcal{O}}(\mathcal{D}) \]
is automatically weakly reduced and the pairing
\[ \text{Alg}_{/ \mathcal{O}}(\lambda^{\text{red}}) : \text{Alg}_{/ \mathcal{O}}(\mathcal{M}^{\text{red}}) \to \text{Alg}_{/ \mathcal{O}}(\mathcal{E}^{\text{red}}) \times \text{Alg}_{/ \mathcal{O}}(\mathcal{D}^{\text{red}}) \]
is automatically reduced. It follows that the map of pairings \( \text{Alg}_{/ \mathcal{O}}(\lambda^{\text{red}}) \to \text{Alg}_{/ \mathcal{O}}(\lambda) \) factors through a map \( \text{Alg}_{/ \mathcal{O}}(\lambda^{\text{red}}) \to \text{Alg}_{/ \mathcal{O}}(\lambda)^* \), which is easily seen to be an equivalence. In particular, we have canonical equivalences
\[ \text{Alg}_{/ \mathcal{O}}(\mathcal{E}^{\text{red}}) \simeq \text{Alg}_{/ \mathcal{O}}(\mathcal{M}) \times_{\text{Alg}_{/ \mathcal{O}}(\mathcal{D})} \{1\} \quad \text{Alg}_{/ \mathcal{O}}(\mathcal{D}^{\text{red}}) \simeq \text{Alg}_{/ \mathcal{O}}(\mathcal{M}) \times_{\text{Alg}_{/ \mathcal{O}}(\mathcal{E})} \{1\} \]
where we use the symbol 1 denote the trivial \( \mathcal{O} \)-algebra object of both \( \mathcal{E} \) and \( \mathcal{D} \).

Proposition 5.2.4.20. Let \( \lambda : \mathcal{M} \to \mathcal{E} \times \mathcal{D} \) be a pairing of \( \infty \)-categories, let \( \mathbf{1}_{\mathcal{M}} \in \mathcal{M} \) be a distinguished object, and let
\[ \lambda^{\text{red}} : \mathcal{M}^{\text{red}} \to \mathcal{E}^{\text{red}} \times \mathcal{D}^{\text{red}} \]
denote the associated reduced pairing (Notation 5.2.4.14). Then:

1. Let \( \mathcal{C} \) be an object of \( \mathcal{E}^{\text{red}} \) having image \( C \in \mathcal{E} \). Suppose that there exists a left universal object \( \mathcal{M} \in \mathcal{M} \)
    lying over \( C \). Then there exists a left universal object \( \mathcal{M} \in \mathcal{M}^{\text{red}} \)
    lying over \( \mathcal{C} \). Moreover, the image of \( \mathcal{M} \) in \( \mathcal{M} \)
    is also left universal.

2. If the pairing \( \lambda \) is left representable, then the pairing \( \lambda^{\text{red}} \) is left representable and the natural map
    \( \lambda^{\text{red}} \to \lambda \) is a left representable morphism of pairings.

Remark 5.2.4.21. In the situation of Proposition 5.2.4.20, if \( \lambda \) is left representable then Proposition 5.2.1.17
supplies a commutative diagram of \( \infty \)-categories
\[ \begin{array}{ccc} \mathcal{E}^{\text{red}} & \xrightarrow{D^{\lambda^{\text{red}}}} & \mathcal{D}^{\text{red}} \\ \downarrow & & \downarrow \\ \mathcal{E} & \xrightarrow{D^{\lambda}} & \mathcal{D}. \end{array} \]

Proof of Proposition 5.2.4.20. Assertion (2) follows immediately from (1). To prove (1), let \( \mathbf{1}_{\mathcal{E}} \) and \( \mathbf{1}_{\mathcal{D}} \)
 denote the images of \( \mathbf{1}_{\mathcal{M}} \) in \( \mathcal{E} \) and \( \mathcal{D} \) and set
\[ \mathcal{E}' = \mathcal{E}_{/ \mathcal{L}} \quad \mathcal{M}' = \mathcal{M}_{/ \mathcal{L}} \quad \mathcal{D}' = \mathcal{D}_{/ \mathcal{L}}, \]
so that we have a pairing \( \lambda' : \mathcal{M}' \to \mathcal{E}' \times \mathcal{D}' \) and we may assume without loss of generality that \( \lambda^{\text{red}} \) is obtained
by applying Construction 5.2.4.12 to \( \lambda' \). In particular, we can identify \( \mathcal{E}^{\text{red}} \) and \( \mathcal{D}^{\text{red}} \) with full subcategories
of \( \mathcal{M}' \), and we can identify \( \mathcal{M}^{\text{red}} \) with the fiber product \( \mathcal{M}_0' \times_{\mathcal{M}'} \mathcal{M}'_1 \)
where the full subcategories
\[ \begin{align*} 
\mathcal{M}'_0 & \subseteq \mathcal{E}' \times_{\text{Fun}(\Delta^1, \mathcal{E}')} \text{Fun}(\Delta^1, \mathcal{M}') \\
\mathcal{M}'_1 & \subseteq \mathcal{D}' \times_{\text{Fun}(\Delta^1, \mathcal{D}')} \text{Fun}(\Delta^1, \mathcal{M}')
\end{align*} \]
are defined as in the proof of Lemma 5.2.4.13. We wish to prove that the \( \infty \)-category \( \mathcal{M}^{\text{red}}_{/ \mathcal{E}^{\text{red}}} \{ \mathcal{C} \} \)
has a final object. Let \( \mathcal{C}' \) denote the image of \( \mathcal{C} \) in \( \mathcal{E}' \) and let \( X \) denote the image of \( \mathcal{C} \) in \( \mathcal{M} \).
The proof of Lemma 5.2.4.13 gives a trivial Kan fibration
\[ \mathcal{M}^{\text{red}}_{/ \mathcal{E}^{\text{red}}} \{ \mathcal{C} \} \to \mathcal{M}_0^{\text{red}}_{/ \mathcal{E}^{\text{red}}} \{ \mathcal{C} \} \simeq \mathcal{M}^{\text{red}}_{/ \mathcal{E}^{\text{red}}}_{/ \mathcal{E}' / \{ \mathcal{C}' \}}. \]
Note that the maps $\mathcal{M}' \to \mathcal{M}$ and $\mathcal{C}' \to \mathcal{C}$ are left fibrations and therefore induce trivial Kan fibrations

$$
\mathcal{M}'^\mathcal{C}' \to \mathcal{M}^\mathcal{X} \quad \mathcal{C}'^\mathcal{C}' \to \mathcal{C}^\mathcal{C}'.
$$

It will therefore suffice to show that the $\infty$-category

$$
\mathcal{M}^\mathcal{X} \times_{\mathcal{C}^\mathcal{C}} \{C\} \simeq (\mathcal{M} \times_{\mathcal{C}} \{C\})^\mathcal{X}
$$

has a final object. We now conclude the proof by applying Proposition T.1.2.13.8 (which implies that the $\infty$-category $(\mathcal{M} \times_{\mathcal{C}} \{C\})^\mathcal{X}$ has a final object which is preserved by the forgetful functor $(\mathcal{M} \times_{\mathcal{C}} \{C\})^\mathcal{X} \to \mathcal{M} \times_{\mathcal{C}} \{C\}$).

**Proof.** Combine Proposition 5.2.3.1, Proposition 5.2.4.20, and Remark 5.2.4.16. □

**Corollary 5.2.4.22.** Let $\lambda^\otimes : \mathcal{M}^\otimes \to \mathcal{C}^\otimes \times_{\mathcal{E}_k} \mathcal{D}^\otimes$ be a pairing of $\mathbb{E}_k$-monoidal $\infty$-categories for $0 < k < \infty$. Assume that the underlying pairing $\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ is left representable and that $\mathcal{D}$ admits totalizations of cosimplicial objects. Then the induced pairing

$$
\text{Alg}_{/\mathcal{E}_k}(\lambda_{\text{red}}^\otimes) : \text{Alg}_{/\mathcal{E}_k}(\mathcal{M}^\text{red}) \to \text{Alg}_{/\mathcal{E}_k}(\mathcal{C}^\text{red}) \times \text{Alg}_{/\mathcal{E}_k}(\mathcal{D}^\text{red})
$$

is left representable.

**Proof.** Combine Proposition 5.2.3.1, Proposition 5.2.4.20, and Remark 5.2.4.16. □

### 5.2.5 Koszul Duality for $\mathbb{E}_k$-Algebras

Fix an integer $k \geq 0$. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category containing a unit object $\mathbf{1} \in \mathcal{C}$, which we will regard as a trivial $\mathbb{E}_k$-algebra object of $\mathcal{C}$. Suppose we are given a pair of $\mathbb{E}_k$-algebra objects $A, B \in \text{Alg}(\mathcal{C})$ which are equipped with augmentations $\epsilon_A : A \to \mathbf{1}$ and $\epsilon_B : B \to \mathbf{1}$. We let $\text{Pair}^{(k)}(A, B)$ denote the homotopy fiber product

$$
\text{Map}_{\text{Alg}_{/\mathcal{E}_k}(\mathcal{C})}(A \otimes B, \mathbf{1}) \times_{\text{Map}_{\text{Alg}_{/\mathcal{E}_k}(\mathcal{C})}(A, \mathbf{1}) \times \text{Map}_{\text{Alg}_{/\mathcal{E}_k}(\mathcal{C})}(B, \mathbf{1})} \{(\epsilon_A, \epsilon_B)\}.
$$

We will refer to the points of $\text{Pair}^{(k)}(A, B)$ as pairings of $A$ with $B$. More informally: a pairing of $A$ with $B$ is an augmentation on the tensor product $A \otimes B$ which extends the given augmentations $\epsilon_A$ and $\epsilon_B$.

The construction $(A, B) \mapsto \text{Pair}^{(k)}(A, B)$ is contravariantly functorial in $A$ and $B$. In particular, given a pairing $\eta \in \text{Pair}^{(k)}(A, B)$ and another augmented algebra object $B' \in \text{Alg}_{/\mathcal{E}_k}^{\text{aug}}(\mathcal{C})$, evaluation on $\eta$ determines a canonical map

$$
\theta_{B'} : \text{Map}_{\text{Alg}_{/\mathcal{E}_k}^{\text{aug}}(\mathcal{C})}(B', B) \to \text{Pair}^{(k)}(A, B').
$$

We will say that the pairing $\eta$ exhibits $B$ as a Koszul dual of $A$ if, for every object $B' \in \text{Alg}_{/\mathcal{E}_k}^{\text{aug}}(\mathcal{C})$, the map $\theta_{B'}$ is a homotopy equivalence. In this case, the object $B \in \text{Alg}_{/\mathcal{E}_k}^{\text{aug}}(\mathcal{C})$ is determined by $A$ up to a contractible space of choices. Similarly, we will say that a pairing $\eta$ exhibits $A$ as a Koszul dual of $B$ if, for every object $A' \in \text{Alg}_{/\mathcal{E}_k}^{\text{aug}}(\mathcal{C})$, evaluation on $\eta$ induces a homotopy equivalence

$$
\text{Map}_{\text{Alg}_{/\mathcal{E}_k}^{\text{aug}}(\mathcal{C})}(A', B) \to \text{Pair}^{(k)}(A', B).
$$

Our goal in this section is to prove the following result:

**Proposition 5.2.5.1.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category and let $k \geq 0$ be an integer. Assume that:

1. The $\infty$-category $\mathcal{C}$ admits totalizations of cosimplicial objects.

2. For each object $C \in \mathcal{C}$, the functor $D \mapsto \text{Map}_{\mathcal{C}}(C \otimes D, \mathbf{1})$ is representable by an object of $\mathcal{C}$.

Then for every augmented algebra object $B \in \text{Alg}_{/\mathcal{E}_k}^{\text{aug}}(\mathcal{C})$, there exists a pairing $A \otimes B \to \mathbf{1}$ which exhibits $A$ as a Koszul dual of $B$. 
5.2. BAR CONSTRUCTIONS AND KOSZUL DUALITY

In what follows, we will restrict our attention to the case $k > 0$ (in the case $k = 0$, Proposition 5.2.5.1 is almost tautological: see Example 5.2.5.31). For many applications, it will be convenient to have a version of Proposition 5.2.5.1 which does not require the monoidal structure on $\mathcal{C}$ to be symmetric. Let us begin by formulating a “noncommutative” version of Proposition 5.2.5.1 in the case $k = 1$. Note that if $\mathcal{C}$ is a monoidal category, then the unit object $1$ can be identified with the endomorphism object $\text{End}(1)$ (see §4.7.2). Consequently, for any algebra object $R \in \text{Alg}(\mathcal{C})$, the data of an augmentation $\epsilon : R \to 1$ is equivalent to the data of a left $R$-module on the object $1 \in \mathcal{C}$. If the monoidal structure on $\mathcal{C}$ is symmetric and $R$ factors as a tensor product $A \otimes B$, then this is equivalent to the data of an $A \otimes B^{\text{rev}}$ bimodule structure on $1 \in \mathcal{C}$ (see §4.6.3). If the monoidal structure on $\mathcal{C}$ is not symmetric, then we cannot generally regard the tensor product $A \otimes B$ as an algebra object of $\mathcal{C}$; however, we can still consider bimodules over $A$ and $B^{\text{rev}}$. The only fine point is that here we should regard $B$ not as an algebra object of the monoidal $\infty$-category $\mathcal{C}$, but of the monoidal $\infty$-category $\mathcal{C}^{\text{rev}}$ (see Remark 4.1.1.8). This motivates the following:

**Definition 5.2.5.2.** Let $\mathcal{C}$ be a monoidal $\infty$-category. Suppose we are given augmented algebra objects $A, B \in \text{Alg}^{\text{aug}}(\mathcal{C})$. Let us abuse notation by identifying the augmentations on $A$ and $B$ with objects $\epsilon_A \in \text{LMod}_A(\mathcal{C}), \epsilon_B \in \text{RMod}_B(\mathcal{C})$ lying over the unit object $1 \in \mathcal{C}$. We let $\text{Pair}^{(1)}(A, B)$ denote the fiber product

$$A \text{BMod}_D(\mathcal{C}) \times \text{LMod}_A(\mathcal{C}) \times \text{RMod}_B(\mathcal{C}) \{ (\epsilon_A, \epsilon_B) \}.$$

**Remark 5.2.5.3.** If the monoidal structure on $\mathcal{C}$ is symmetric, then for $A, B \in \text{Alg}^{\text{aug}}(\mathcal{C}) \simeq \text{Alg}^{\text{aug}}_{\mathcal{E}_k}(\mathcal{C})$ we have a canonical homotopy equivalence $\text{Pair}^{(1)}(A, B) \simeq \text{Pair}^{(1)}(A, B^{\text{rev}})$. The discussion preceding Definition 5.2.5.2 sketches a construction of this equivalence; we will give another argument (in the more general context of $\mathcal{E}_k$-algebras) below.

**Warning 5.2.5.4.** In the setting of Definition 5.2.5.2, the construction $(A, B) \mapsto \text{Pair}^{(1)}(A, B)$ is generally not symmetric in $A$ and $B$ (see Remark 5.2.5.17).

Our next step is to realize the construction $(A, B) \mapsto \text{Pair}^{(1)}(A, B)$ as arising from a pairing between monoidal $\infty$-categories.

**Definition 5.2.5.5.** Let $\mathcal{C}$ be a monoidal $\infty$-category with unit object $1$. Then the construction $(C, D) \mapsto \text{Map}_\mathcal{C}(C \otimes D, 1)$ determines a functor $\mathcal{C}^{\text{op}} \times \mathcal{C}^{\text{op}} \to \mathcal{S}$ which classifies a right fibration

$$\lambda : \text{Dual}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}.$$  

We will refer to $\lambda$ as the **duality pairing** on $\mathcal{C}$. We will identify the objects of $\text{Dual}(\mathcal{C})$ with triples $(C, D, \mu)$ where $C, D \in \mathcal{C}$ and $\mu : C \otimes D \to 1$ is a morphism in $\mathcal{C}$.

**Remark 5.2.5.6.** Let $\mathcal{C}$ be a monoidal $\infty$-category and let $(C, D, \mu)$ be an object of $\text{Dual}(\mathcal{C})$. Then $(C, D, \mu)$ is left universal (with respect to the duality pairing $\lambda : \text{Dual}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}$) if and only if for every object $D' \in \mathcal{C}$, composition with $\mu$ induces a homotopy equivalence

$$\text{Map}_\mathcal{C}(D', D) \to \text{Map}_\mathcal{C}(C \otimes D', 1).$$

In this case, we will say that $\mu$ exhibits $D$ as a weak left dual of $C$. The object $D$ is determined uniquely up to equivalence and we will indicate the dependence of $D$ on $C$ by $D =^\vee C$.

Similarly, the object $(C, D, \mu)$ is right universal with respect to $\lambda$ if and only if for each $C' \in \mathcal{C}$, composition with $\mu$ induces a homotopy equivalence

$$\text{Map}_\mathcal{C}(C', C) \to \text{Map}_\mathcal{C}(C' \otimes D, 1).$$

In this case, we will say that $\mu$ exhibits $C$ as a weak right dual of $D$. The object $C$ is uniquely determined up to equivalence, and we will indicate the dependence of $C$ on $D$ by writing $C = D^\vee$. 
Remark 5.2.5.7. Let $\mathcal{C}$ be a monoidal $\infty$-category and let $(C, D, \mu) \in \mathrm{Dual}(\mathcal{C})$. If $\mu$ exhibits $D$ as a left dual of $C$ (in the sense of Definition 4.6.1.7), then $\mu$ exhibits $D$ as a weak left dual of $C$ (in the sense of Remark 5.2.5.6). However, the converse fails. For example, if $\mathcal{C} = \mathcal{N}(\mathrm{Vect}_\kappa)$ for some field $\kappa$, then a map $\mu : V \otimes_s W \to \kappa$ exhibits $W$ as a weak left dual of $V$ when it induces an isomorphism $W \to \mathrm{Hom}_\kappa(V, \kappa)$, but such a map exhibits $W$ as a left dual of $V$ only when $V$ is finite-dimensional.

Remark 5.2.5.8. Let $\mathcal{C}$ be a presentable monoidal $\infty$-category for which the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. For each object $C \in \mathcal{C}$, the functors

$$D \mapsto \mathrm{Map}_\mathcal{C}(C \otimes D, 1) \quad D \mapsto \mathrm{Map}_\mathcal{C}(D \otimes C, 1)$$

carry colimits in $\mathcal{D}$ to limits in $\mathcal{S}$, and are therefore representable (Proposition T.5.5.2.2). It follows that the duality correspondence $\mathrm{Dual}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}$ is both left and right representable.

Our next observation is that if $\mathcal{C}$ is a monoidal $\infty$-category, then the duality pairing $\mathrm{Dual}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}$ can be promoted to a pairing of monoidal $\infty$-categories. The only caveat is that on the second copy of $\mathcal{C}$, we should use the reverse of the usual monoidal structure.

Construction 5.2.5.9. Let $\mathcal{M}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{C}$ and $\mathcal{D}$. Let $\mathcal{D}^{\text{rev}}$ denote the same $\infty$-category $\mathcal{D}$ but endowed with the reversed monoidal structure. Using the constructions of §4.6.3, we can regard $\mathcal{M}$ as left-tensored over the monoidal $\infty$-category $\mathcal{C} \times \mathcal{D}^{\text{rev}}$. For each object $M \in \mathcal{M}$, we let $(\mathcal{C} \times \mathcal{D}^{\text{rev}})([M])$ denote the monoidal $\infty$-category given in Definition 4.7.2.1. The projection map $(\mathcal{C} \times \mathcal{D}^{\text{rev}})([M]) \to \mathcal{C} \times \mathcal{D}^{\text{rev}}$ is a right fibration, so that we obtain a pairing of monoidal $\infty$-categories

$$\lambda^\otimes : (\mathcal{C} \times \mathcal{D}^{\text{rev}})([M])^\otimes \to \mathcal{C}^\otimes \times_{\mathcal{A}_{ss}} (\mathcal{D}^{\text{rev}})^\otimes.$$ 

In the special case where $\mathcal{C}$ is a monoidal $\infty$-category with unit object $1$ which we regard as bitensored over itself, we can identify $(\mathcal{C} \times \mathcal{C}^{\text{rev}})([1])$ with the $\infty$-category $\mathrm{Dual}(\mathcal{C})$. It follows that we can regard $\mathrm{Dual}(\mathcal{C})$ as a monoidal $\infty$-category and that the duality pairing refines to a pairing of monoidal $\infty$-categories

$$\mathrm{Dual}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \times_{\mathcal{A}_{ss}} (\mathcal{C}^{\text{rev}})^\otimes.$$ 

Remark 5.2.5.10. Let $\mathcal{C}$ be a monoidal $\infty$-category. Assume that every object $C \in \mathcal{C}$ admits a weak left dual $^\vee C$, so that the duality pairing $\mathrm{Dual}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{rev}}$ is left representable. It follows from Remark 5.2.2.25 that the construction $C \mapsto \vee C$ determines a lax monoidal functor $\mathcal{C}^{\text{op}} \to \mathcal{C}^{\text{rev}}$. In particular, for every pair of objects $C, D \in \mathcal{C}$, we have a canonical map

$$\vee C \otimes \vee D \to \vee (C \otimes D).$$

This map is an equivalence if $D$ is left dualizable, but not in general.

Similarly, if every object $C \in \mathcal{C}$ is weakly right dualizable, then the construction $C \mapsto C^\vee$ determines a lax monoidal functor $\mathcal{C}^{\text{rev}} \to \mathcal{C}^{\text{op}}$ to $\mathcal{C}$.

Remark 5.2.5.11. Let $\mathcal{C}$ be a monoidal $\infty$-category. At the level of objects, the tensor product on $\mathrm{Dual}(\mathcal{C})$ is given by

$$(C, D, \mu) \otimes (C', D', \mu') = (C \otimes C', D' \otimes D, \nu)$$

where $\nu$ is given by the composition

$$C \otimes C' \otimes D' \otimes D \xrightarrow{\text{id} \otimes \mu' \otimes \text{id}} C \otimes D \xrightarrow{\mu} 1.$$ 

Remark 5.2.5.12. Let $\mathcal{C}$ be a monoidal $\infty$-category. Then Theorem 4.7.2.34 determines an equivalence of $\infty$-categories

$$\mathrm{Alg}(\mathrm{Dual}(\mathcal{C})) \simeq \mathrm{BMod}(\mathcal{C}) \times \mathcal{C} 1.$$
In particular, if we are given a pair of objects $A \in \mathcal{C}$, $B \in \mathcal{C}$, then the fiber
\[ \text{Alg(Dual(1))} \times_{\text{Alg(1)}} \{ (A, B) \} \]
can be identified with the Kan complex $\mathcal{A}\text{Mod}_{B^{\text{rev}}}(1) \times_{\mathcal{A}} \{ 1 \}$ of $A$-$B^{\text{rev}}$ bimodule structures on the unit object $1$.

**Remark 5.2.5.13.** Let $\mathcal{C}$ be a monoidal $\infty$-category, let
\[ \lambda : \text{Dual}(\mathcal{C}) \rightarrow \mathcal{C} \times \mathcal{C}^{\text{rev}} \]
be the duality pairing, and let
\[ \lambda^{\text{red}} : \text{Dual}(\mathcal{C})^{\text{rev}} \rightarrow \mathcal{C}^{\text{red}} \times (\mathcal{C}^{\text{rev}})^{\text{red}} \]
be the associated reduced pairing (Notation 5.2.4.14). Unwinding the definitions, we see that $\mathcal{C}^{\text{red}}$ and $(\mathcal{C}^{\text{rev}})^{\text{red}}$ can be identified with the $\infty$-category $\mathcal{C}_{1}/1$ of augmented $E_{0}$-algebra objects in $\mathcal{C}$. Using Example 5.2.4.18 and Remark 5.2.4.19, we see that $\lambda^{\text{red}}$ is a pairing of monoidal $\infty$-categories and that the induced pairing $\text{Alg}(\lambda^{\text{red}})$ can be identified with a right fibration
\[ (\mathcal{B}\text{Mod}(\mathcal{C}) \times_{\mathcal{C}} 1) \rightarrow \mathcal{A}\text{ug}(\mathcal{C}) \times \mathcal{A}\text{ug}(\mathcal{C}^{\text{rev}}) \]
classified by the functor $(A, B) \mapsto \text{Pair}^{(1)}(A, B^{\text{rev}})$ (alternatively, one can regard this as a precise definition of the functor $\text{Pair}^{(1)}$ which appears in Definition 5.2.5.2).

Combining Remark 5.2.5.13 with Corollary 5.2.4.22, we obtain the following analogue of Proposition 5.2.5.1:

**Proposition 5.2.5.14.** Let $\mathcal{C}$ be a monoidal $\infty$-category. Assume that:

1. The $\infty$-category $\mathcal{C}$ admits totalizations of cosimplicial objects.
2. For each object $C \in \mathcal{C}$, there exists a weak right dual $C^{\vee} \in \mathcal{C}$.

Then for every augmented algebra object $B \in \mathcal{A}\text{ug}(\mathcal{C})$, there exists an augmented algebra $A \in \mathcal{A}\text{ug}(\mathcal{C})$ and a point $\eta \in \text{Pair}^{(1)}(A, B)$ with the following universal property: for every algebra object $A \in \mathcal{A}\text{ug}(\mathcal{C})$, evaluation on $\eta$ induces a homotopy equivalence
\[ \text{Map}_{\mathcal{A}\text{ug}(\mathcal{C})}(A', A) \rightarrow \text{Pair}^{(1)}(A', B). \]

**Remark 5.2.5.15.** In the situation of Proposition 5.2.5.1, suppose that the $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, and that the tensor product on $\mathcal{C}$ preserves geometric realizations of simplicial objects. Then Proposition 5.2.3.10 implies that the algebra $A$ can be identified with the right dual $\text{Bar}(B)^{\vee}$, where $\text{Bar}(B) \in \text{Alg}(\mathcal{C}^{\text{op}})$ denotes the bar construction on the augmented algebra $B$.

**Remark 5.2.5.16.** Let $\mathcal{C}$ be a monoidal $\infty$-category and suppose we are given an augmented algebra object $B \in \mathcal{A}\text{ug}(\mathcal{C})$. Let $M = \text{RMod}_{B}(\mathcal{C})$, so that $M$ is an $\infty$-category left-tensored over $\mathcal{C}$. Using the augmentation on $B$, we can view the unit object $1 \in \mathcal{C}$ as a right $B$-module. Theorem 4.3.2.7 supplies an equivalence of $\infty$-categories $\text{LMod}_{A}(M) \simeq \mathcal{A}\text{Mod}_{B}(\mathcal{C})$ which depends functorially on $A$. It follows that a pairing $\eta \in \text{Pair}^{(1)}(A, B)$ induces a homotopy equivalence $\text{Map}_{\mathcal{A}\text{ug}(\mathcal{C})}(A', A) \rightarrow \text{Pair}^{(1)}(A', B)$ for all $A' \in \mathcal{A}\text{ug}(\mathcal{C})$ if and only if it exhibits $A$ as an endomorphism object of $1$ in the $\infty$-category $M$, in the sense of §4.7.2.

**Remark 5.2.5.17.** In the situation of Proposition 5.2.5.1, suppose that condition (1) is satisfied and that for every object $C \in \mathcal{C}$ there exists a weak left dual $\vee C \in \mathcal{C}$. Then for every augmented algebra object $B \in \mathcal{A}\text{ug}(\mathcal{C})$ we can find an augmented algebra $A \in \mathcal{A}\text{ug}(\mathcal{C})$ and a point $\eta \in \text{Pair}^{(1)}(B, A)$ with which induces homotopy equivalences $\text{Map}_{\mathcal{A}\text{ug}(\mathcal{C})}(A', A) \rightarrow \text{Pair}^{(1)}(B, A')$ for all $A' \in \mathcal{A}\text{ug}(\mathcal{C})$. If $\mathcal{C}$ admits geometric realizations of simplicial objects and the tensor product on $\mathcal{C}$ preserves geometric realizations of simplicial objects, then the algebra $A$ can be realized explicitly as the left dual $\vee \text{Bar}(B)$. In particular, we note that this algebra generally does not agree with the algebra $\text{Bar}(B)^{\vee}$ appearing in Remark 5.2.5.15, even when both are well-defined (see Warning 5.2.5.4).
Our next goal is to generalize Proposition 5.2.5.14 to the setting of \( E_k \)-monoidal \( \infty \)-categories for \( k \geq 1 \). We begin by introducing a construction which “reverses” the multiplication on an \( E_k \)-algebra (or an \( E_k \)-monoidal \( \infty \)-category).

**Construction 5.2.5.18.** Fix \( 1 \leq k < \infty \). The open cube \( \square^k = (-1,1)^k \) is equipped with a canonical reflection \( \sigma : \square^k \to \square^k \), given in coordinates by

\[
\sigma(t_1, t_2, t_3, \ldots, t_k) = (t_1, t_2, t_3, \ldots, -t_k).
\]

Conjugation by \( \sigma \) determines an automorphism of the topological operad \( ^tE_k \) (which is the identity map on objects and replaces each rectilinear embedding \( f : \square^k \to \square^k \) by the conjugate embedding \( \sigma \circ f \circ \sigma^{-1} \)). The involution \( \sigma \) induces an involution on the \( \infty \)-operad \( \mathcal{E}_k^\infty \), which we will denote by

\[
\text{rev} : \mathcal{E}_k^\infty \to \mathcal{E}_k^\infty.
\]

If \( q : \mathcal{C}^\circ \to \mathcal{E}_k^\infty \) is an \( E_k \)-monoidal \( \infty \)-category, we let \((\mathcal{C}^{\text{rev}})^\circ\) denote the \( \mathcal{E}_k^\infty \)-monoidal \( \infty \)-category given by the composition

\[
\mathcal{C}^\circ \xrightarrow{q} \mathcal{E}_k^\infty \xrightarrow{\text{rev}} \mathcal{E}_k^\infty.
\]

We will refer to \((\mathcal{C}^{\text{rev}})^\circ\) as the reverse of the \( E_k \)-monoidal \( \infty \)-category \( \mathcal{C}^\circ \). In this case, composition with \( \sigma \) induces an isomorphism of simplicial sets

\[
\text{Alg}_{/\mathcal{E}_k}(\mathcal{C}) \simeq \text{Alg}_{/\mathcal{E}_k}(\mathcal{C}^{\text{rev}}),
\]

which we will denote by \( A \mapsto A^{\text{rev}} \).

**Remark 5.2.5.19.** Many variants on Construction 5.2.5.18 are possible. Every element of the group \( G = \Sigma_k \ltimes \{\pm 1\}^k \) determines an automorphism \( \sigma \) of \( \square^k \) of the form

\[
(t_1, \ldots, t_k) \mapsto (\pm t_{\sigma(1)}, \ldots, \pm t_{\sigma(k)}),
\]

which in turn determines an automorphism of the \( \infty \)-operad \( \mathcal{E}_k^\infty \) given by conjugation by \( \sigma \) on each rectilinear embedding from \( \square^k \) to itself. In §5.4.2, we will see that this action of \( G \) on \( \mathcal{E}_k^\infty \) extends (up to homotopy) to an action of the orthogonal group \( O(k) \) on \( \mathcal{E}_k^\infty \). In particular, any two signed permutations \( \sigma, \sigma' \in G \) which belong to the same connected component of \( O(k) \) determine equivalent maps from \( \mathcal{E}_k^\infty \) to itself (the equivalence is not canonical: it depends on a choice of path from \( \sigma \) to \( \sigma' \) in the orthogonal group \( O(k) \)).

**Remark 5.2.5.20.** Let \( \mathcal{C}^\circ \to \text{Comm}^\circ \) be a symmetric monoidal \( \infty \)-category and set \( \mathcal{D}^\circ = \mathcal{C}^\circ \times_{\text{Comm}^\circ} \mathcal{E}_k^\infty \) be the associated \( E_k \)-monoidal \( \infty \)-category. Then there is a canonical isomorphism \( \mathcal{D}^\circ \simeq (\mathcal{D}^{\text{rev}})^\circ \). Beware, however, that the reversal isomorphism

\[
\text{Alg}_{/\mathcal{E}_k}(\mathcal{C}) \simeq \text{Alg}_{/\mathcal{E}_k}(\mathcal{D}) \overset{\text{rev}}{\to} \text{Alg}_{/\mathcal{E}_k}(\mathcal{D}^{\text{rev}}) \simeq \text{Alg}_{/\mathcal{E}_k}(\mathcal{C})
\]

is not the identity functor (it is given by composition with \( \text{rev} : \mathcal{E}_k^\infty \to \mathcal{E}_k^\infty \)).

**Remark 5.2.5.21.** Let \( \mathcal{C}^\infty \) be the \( \infty \)-category of (small) \( \infty \)-categories, which we regard as endowed with the Cartesian symmetric monoidal structure. Then we can identify \( E_k \)-monoidal \( \infty \)-categories with \( E_k \)-algebra objects of \( \mathcal{C}^\infty \). Under this identification, the reversal isomorphism \( \text{Alg}_{/\mathcal{E}_k}(\mathcal{C}^\infty) \simeq \text{Alg}_{/\mathcal{E}_k}(\mathcal{C}^\infty) \) of Remark 5.2.5.20 corresponds to the the construction \( \mathcal{C}^\circ \to (\mathcal{C}^{\text{rev}})^\circ \) of Construction 5.2.5.18.

**Remark 5.2.5.22.** In the special case \( k = 1 \), the reversal isomorphism \( \text{rev} : \mathcal{E}_1^\infty \to \mathcal{E}_1^\infty \) fits into a commutative diagram

\[
\begin{array}{c}
\mathcal{E}_1^\infty \\
\downarrow \text{rev} \\
\mathcal{E}_1^\infty
\end{array}
\quad
\begin{array}{c}
\text{Ass}^\circ \\
\downarrow \sigma \\
\text{Ass}^\circ
\end{array}
\]
where $\sigma$ denotes the involution of Remark 4.1.1.8 and the vertical maps are given by the equivalence of Example 5.1.0.7. Consequently, the notion of reversal for $E_1$-monoidal $\infty$-categories and $E_1$-algebras agrees with the analogous notion for monoidal $\infty$-categories and associative algebras studied in Chapter 4.

**Remark 5.2.5.23.** Suppose we are given integers $k \geq 0$ and $k' \geq 1$. Then the reversal isomorphisms $\text{rev}_{k'} : E_k^\otimes \to E_k^\otimes$ and $\text{rev}_{k+k'} : E_{k+k'}^\otimes \to E_{k+k'}^\otimes$ fit into a commutative diagram

\[
\begin{array}{ccc}
E_k^\otimes \times E_k^\otimes & \longrightarrow & E_{k+k'}^\otimes \\
\downarrow \text{id} \times \text{rev}_{k'} & & \downarrow \text{rev}_{k+k'} \\
E_k^\otimes \times E_{k'}^\otimes & \longrightarrow & E_{k+k'}^\otimes,
\end{array}
\]

where the horizontal maps are the bifunctors of $\infty$-operads given in Construction 5.1.2.1. In particular:

(a) If $\mathcal{C}$ is an $E_{k+k'}$-monoidal $\infty$-category, then composition with $\text{rev}_{k'}$ induces an equivalence of $E_k$-monoidal $\infty$-categories

\[\rho : \text{Alg}_{E_k/E_{k+k'}}(\mathcal{C}) \simeq (\text{Alg}_{E_{k+k'}/E_{k+k'}}(\mathcal{C}^{\text{rev}}))^{\otimes} \]

(b) The diagram of $\infty$-categories

\[
\begin{array}{ccc}
\text{Alg}_{/E_{k+k'}}(\mathcal{C}) & \xrightarrow{\text{rev}} & \text{Alg}_{/E_{k+k'}}(\mathcal{C}^{\text{rev}}) \\
\downarrow & & \downarrow \\
\text{Alg}_{/E_k}(\text{Alg}_{E_{k+k'}/E_{k+k'}}(\mathcal{C}^{\text{rev}})) & \xrightarrow{\rho} & \text{Alg}_{/E_k}(\text{Alg}_{E_{k+k'}/E_{k+k'}}(\mathcal{C}^{\text{rev}}))
\end{array}
\]

commutes (here the vertical maps are equivalences by Theorem 5.1.2.2).

**Example 5.2.5.24.** For each integer $k \geq 0$, one can define two different embeddings $\iota, \iota' : E_k^\otimes \to E_{k+1}^\otimes$, given by the compositions

\[
\begin{align*}
\iota : E_k^\otimes & \simeq E_k^\otimes \times \{1\} \hookrightarrow E_k^\otimes \times E_1^\otimes \to E_{k+1}^\otimes \\
\iota' : E_k^\otimes & \simeq \{1\} \times E_k^\otimes \hookrightarrow E_1^\otimes \times E_k^\otimes \to E_{k+1}^\otimes.
\end{align*}
\]

Using Remark 5.2.5.23, we see that these embeddings fit into commutative diagrams

\[
\begin{array}{ccc}
E_k^\otimes & \xrightarrow{\text{id}} & E_k^\otimes \\
\downarrow \iota & & \downarrow \iota' \\
E_{k+1}^\otimes & \xrightarrow{\text{rev}} & E_{k+1}^\otimes
\end{array}
\quad
\begin{array}{ccc}
E_k^\otimes & \xrightarrow{\text{rev}} & E_k^\otimes \\
\downarrow \iota' & & \downarrow \iota' \\
E_{k+1}^\otimes & \xrightarrow{\text{rev}} & E_{k+1}^\otimes
\end{array}
\]

**Remark 5.2.5.25.** In what follows, it will be convenient to regard the $\infty$-operad $E_\infty^\otimes$ as the colimit of the sequence

\[E_1^\otimes \to E_2^\otimes \to E_3^\otimes \to \cdots.
\]

It follows from Example 5.2.5.24 that the reversal involutions on the $\infty$-operads $E_k^\otimes$ are compatible with the transition maps in this sequence and therefore determine an involution $\text{rev} : E_\infty^\otimes \to E_\infty^\otimes$. Of course, this automorphism is automatically homotopic to the identity (since $E_\infty^\otimes$ is a final object in the $\infty$-category of $\infty$-operads).

**Example 5.2.5.26.** Let $k \geq 1$ and let $\mathcal{C}^\otimes$ be an $E_k$-monoidal $\infty$-category, which we can identify with an object of

\[\text{Alg}_{E_k}(\text{Cat}_\infty) \simeq \text{Alg}_{E_{k-1}}(\text{Alg}(\text{Cat}_\infty)).\]

Then the $E_k$-monoidal $\infty$-category $(\mathcal{C}^{\text{rev}})$ is obtained from $\mathcal{C}^\otimes$ by composing with the automorphism of $\text{Alg}_{E_{k-1}}(\text{Alg}(\text{Cat}_\infty))$ induced by the reversal automorphism $\text{rev} : \text{Alg}(\text{Cat}_\infty) \to \text{Alg}(\text{Cat}_\infty)$. 
Construction 5.2.5.27. The formation of duality pairings
\[ \mathcal{C}^\otimes \mapsto (\text{Dual}(\mathcal{C}))^\otimes \to \mathcal{C}^\otimes \times_{A_{ss}} (\mathcal{C}^{\text{rev}})^\otimes \]
outlined in Construction 5.2.5.9 determines a functor \( \text{Alg}(\mathcal{C}_{\infty}) \to \text{Alg}(\text{CPair}) \). It is easy to see that this functor commutes with finite products and therefore induces a map
\[
\text{Alg}_{\mathcal{E}_k}(\mathcal{C}_{\infty}) \simeq \text{Alg}_{\mathcal{E}_{k-1}}(\text{Alg}(\mathcal{C}_{\infty})) \to \text{Alg}_{\mathcal{E}_{k-1}}(\text{Alg}(\text{CPair})) \simeq \text{Alg}_{\mathcal{E}_k}(\text{CPair})
\]
for \( k \geq 1 \). This map assigns to each \( \mathcal{E}_k \)-monoidal \( \infty \)-category \( \mathcal{C}^\otimes \) a pairing of \( \mathcal{E}_k \)-monoidal \( \infty \)-categories
\[
\text{Dual}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \times_{\mathcal{E}_k} (\mathcal{C}^{\text{rev}})^\otimes,
\]
which we will refer to as the duality pairing associated to \( \mathcal{C}^\otimes \).

Warning 5.2.5.28. Construction 5.2.5.27 is not invariant under automorphisms of the \( \infty \)-operad \( \mathcal{E}_k^\otimes \): it depends on a choice of equivalence between \( \mathcal{E}_k^\otimes \) and the operadic tensor product of \( \mathcal{E}_{k-1}^\otimes \) with the associative \( \infty \)-operad \( \text{Ass}^\otimes \). One can see this already at the level of the underlying \( \infty \)-categories: objects of the \( \infty \)-category \( \text{Dual}(\mathcal{C}) \) are given by triples \((C, D, \mu)\) where \( C, D \in \mathcal{C} \) and \( \mu : C \otimes \eta D \to 1 \) is a morphism in \( \mathcal{C} \), where \( \eta \) is the “north pole” in the sphere \( S^{k-1} \simeq \text{Bin} \mathcal{E}_k \); one can obtain other pairings (which are noncanonically equivalent for \( k > 1 \)) by choosing other points \( \eta \in S^{k-1} \).

Remark 5.2.5.29. Let \( \mathcal{C} \) be an \( \mathcal{E}_k \)-monoidal \( \infty \)-category for \( k \geq 1 \). Then we have a canonical equivalence of \( \infty \)-categories
\[
\text{Alg}_{/\mathcal{E}_k}(\text{Dual}(\mathcal{C})) \simeq \text{Alg}_{/\mathcal{E}_{k-1}}(\text{Alg}_{\mathcal{E}_{k-1}/\mathcal{E}_k}(\text{Dual}(\mathcal{C}))) \simeq \text{Alg}_{/\mathcal{E}_{k-1}}(\text{BMod}(\mathcal{C}) \times_{\mathcal{C}} 1) \simeq \text{BMod}(\text{Alg}_{\mathcal{E}_{k-1}/\mathcal{E}_k}(\mathcal{C})) \times_{\text{Alg}_{\mathcal{E}_{k-1}/\mathcal{E}_k}(\mathcal{C})} 1.
\]
In other words, we can identify the objects of \( \text{Alg}_{/\mathcal{E}_k}(\text{Dual}(\mathcal{C})) \) with triples \((A, B, \mu)\), where \( A \) is an \( \mathcal{E}_k \)-algebra in \( \mathcal{C} \), \( B \) is an \( \mathcal{E}_k \)-algebra in \( \mathcal{C} \), and \( \mu \) is the data of an \( A-B \) bimodule structure on the trivial algebra \( 1 \in \text{Alg}_{\mathcal{E}_{k-1}/\mathcal{E}_k}(\mathcal{C}) \).

Variant 5.2.5.30. Let \( \mathcal{C} \) be an \( \mathcal{E}_k \)-monoidal \( \infty \)-category for \( k \geq 1 \). Suppose we are given a morphism of \( \infty \)-operads \( \mathcal{O}^\otimes \to \mathcal{E}_k^\otimes \) which factors through the inclusion \( \iota : \mathcal{E}_k^\otimes \to \mathcal{E}_k^\otimes \) of Example 5.2.5.24. Then the \( \infty \)-category \( \text{Alg}_{\mathcal{O}/\mathcal{E}_k}(\mathcal{C}) \) inherits a monoidal structure. Moreover, if \( \lambda : \text{Dual}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\text{rev}} \) is the duality pairing, then the induced pairing
\[
\text{Alg}_{\mathcal{O}/\mathcal{E}_k}(\lambda) : \text{Alg}_{\mathcal{O}/\mathcal{E}_k}(\text{Dual}(\mathcal{C})) \times \text{Alg}_{\mathcal{O}/\mathcal{E}_k}(\mathcal{C}) \times \text{Alg}_{\mathcal{O}/\mathcal{E}_k}(\mathcal{C}^{\text{rev}})
\]
is classified by the functor \((A, B) \mapsto \text{Map}_{\text{Alg}_{\mathcal{O}/\mathcal{E}_k}(\mathcal{C})}(A \otimes B^{\text{rev}}, 1) \).

Example 5.2.5.31. In the situation of Variant 5.2.5.30, we can take \( k = \infty \) and \( \mathcal{O}^\otimes = \mathcal{E}_0^\otimes \). Unwinding the definitions, we see that the pairing \( \text{Alg}_{\mathcal{E}_0/\mathcal{E}_n}(\lambda^{\text{red}}) \simeq \lambda^{\text{red}} \) is classified by the functor
\[
\text{Pair}^0 : \text{Alg}_{\mathcal{E}_0}(\mathcal{C}^{\text{op}}) \times \text{Alg}_{\mathcal{E}_0}(\mathcal{C}^{\text{op}}) \to S.
\]
It follows from Proposition 5.2.4.20 that the pairing \( \lambda^{\text{red}} \) is right universal if \( \lambda \) is right universal, which gives a proof of Proposition 5.2.5.1 in the case \( k = 0 \). More concretely: if every object \( C \in \mathcal{C} \) admits a weak right dual \( C^{\vee} \), then the Koszul dual of an augmented \( \mathcal{E}_0 \)-algebra
\[
\begin{array}{ccc}
\alpha & & \beta \\
\downarrow & & \downarrow \\
1 & \to & 1
\end{array}
\]
is given by the augmented $E_0$-algebra

![Diagram](image)

**Construction 5.2.5.32.** Let $\mathcal{C}$ be an $E_k$-monoidal $\infty$-category and let

$$\lambda^\otimes : \text{Dual}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \times_{E_k^\otimes} (\mathcal{C}^{\text{rev}})^\otimes$$

be the associated duality pairing. Then $\lambda^\otimes$ induces a reduced pairing of $E_k$-monoidal $\infty$-categories

$$\left(\lambda^{\text{red}}\right)^\otimes : \left(\text{Dual}(\mathcal{C})^{\text{red}}\right)^\otimes \to \left((\mathcal{C}^{\text{rev}})^{\text{red}}\right)^\otimes.$$  

We have canonical equivalences

$$\text{Alg}_{E/E_k}(\mathcal{C}^{\text{red}}) \simeq \text{Alg}_{E/E_{k-1}}(\text{Alg}_{E_1/E_k}(\mathcal{C}^{\text{red}})) \simeq \text{Alg}_{E/E_{k-1}}(\text{Alg}_{E_1/E_k}(\mathcal{C})) \simeq \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C});$$

a similar calculation yields an identification $\text{Alg}_{E/k}(\mathcal{C}^{\text{rev}}^{\text{red}}) \simeq \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C}^{\text{rev}})$. Identifying $\text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})$ with $\text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})$ via the reversal functor $\text{rev}$, we obtain a pairing of $\infty$-categories

$$\text{Alg}_{E/E_k}(\lambda^{\text{red}}) : \text{Alg}_{E/E_k}(\text{Dual}(\mathcal{C})) \to \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C}) \times \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C}).$$

We let $\text{Pair}^{(k)} : \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})^{\text{op}} \times \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})^{\text{op}} \to S$ denote a functor which classifies the functor $\text{Alg}_{E/E_k}(\lambda^{\text{red}})$.

If $A$ and $B$ are $E_k$-algebra objects of $\mathcal{C}$ equipped with augmentations $\epsilon_A : A \to 1$ and $\epsilon_B : B \to 1$, then we can identify $\epsilon_A$ and $\epsilon_B$ with $E_{k-1}$-algebra objects of $\text{LMod}_A(\mathcal{C})$ and $\text{RMod}_B(\mathcal{C})$ (lying over the trivial $E_{k-1}$-algebra object $1 \in \mathcal{C}$). Unwinding the definitions, we see that $\text{Pair}^{(k)}(A, B)$ is given by the fiber product

$$\text{Alg}_{E/E_{k-1}}(\text{A}\text{B}\text{Mod}_B(\mathcal{C})) \times_{\text{Alg}_{E/E_{k-1}}(\text{LMod}_A(\mathcal{C})) \times \text{Alg}_{E/E_{k-1}}(\text{RMod}_B(\mathcal{C}))} \{ (\epsilon_A, \epsilon_B) \}.$$

More informally, $\text{Pair}^{(k)}(A, B)$ is the space of witnesses to the commutativity of the central left action of $A$ on $1$ via $\epsilon_A$ with the central right action of $B$ on $1$ via $\epsilon_B$.

Invoking Corollary 5.2.4.22, we obtain the following generalization of Proposition 5.2.5.14:

**Proposition 5.2.5.33.** Let $\mathcal{C}$ be an $E_k$-monoidal $\infty$-category. Assume that:

1. The $\infty$-category $\mathcal{C}$ admits totalizations of cosimplicial objects.
2. For each object $C \in \mathcal{C}$, there exists a weak right dual $C^\vee$ with respect to the underlying monoidal structure on $\mathcal{C}$.

Then the pairing

$$\text{Alg}_{E/E_k}(\lambda^{\text{red}}) : \text{Alg}_{E/E_k}(\text{Dual}(\mathcal{C})) \to \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C}) \times \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C}).$$

of Construction 5.2.5.32 is right representable. In other words, for every augmented algebra object $B \in \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})$, there exists an augmented algebra $A \in \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})$ and a point $\eta \in \text{Pair}^{(k)}(A, B)$ with the following universal property: for every algebra object $A' \in \text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})$, evaluation on $\eta$ induces a homotopy equivalence

$$\text{Map}_{\text{Alg}_{E/E_k}^{\text{aug}}(\mathcal{C})}(A', A) \to \text{Pair}^{(k)}(A', B).$$
Remark 5.2.5.34. If \( k > 1 \), then the notion of weak left and right duals for objects \( C \in \mathcal{C} \) are (noncanonically) equivalent to one another.

Example 5.2.5.35. In the situation of Proposition 5.2.5.33, suppose that \( \mathcal{C} \) satisfies the following additional conditions:

1. The unit object \( 1 \in \mathcal{C} \) is both initial and final.
2. For every countable weakly contractible simplicial set \( K \), the \( \infty \)-category \( \mathcal{C} \) admits \( K \)-indexed colimits.

Remark 5.2.5.34. In the situation of Proposition 5.2.5.33, suppose that \( \mathcal{C} \) satisfies the following additional conditions:

1. For every countable weakly contractible simplicial set \( K \), the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves \( K \)-indexed colimits separately in each variable.

It follows from (5) that the construction \( C \mapsto C^\vee \) determines a functor \( \mathcal{C} \to \mathcal{C}^{\text{op}} \) which preserves \( K \)-indexed colimits for every countable weakly contractible simplicial set \( K \). Proposition 5.2.3.15 implies that the forgetful functor \( \text{Alg}_{/k}(\mathcal{C}) \to \mathcal{C} \) admits a left adjoint \( \text{Free} : \mathcal{C} \to \text{Alg}_{/k}(\mathcal{C}) \). For each \( C \in \mathcal{C} \), Proposition 5.2.5.33 guarantees that there exists an algebra object \( A \in \text{Alg}_{/k}(\mathcal{C}) \) and a point \( \eta \in \text{Pair}^{(k)}(A, \text{Free}(C)) \) with the following universal property: for each \( A' \in \text{Alg}_{/k}(\mathcal{C}) \), evaluation on \( \eta \) induces a homotopy equivalence

\[
\text{Map}_{\text{Alg}_{/k}(\mathcal{C})}(A', A) \to \text{Pair}^{(k)}(A', \text{Free}(C)).
\]

Using Propositions 5.2.3.10 and 5.2.3.15, we see that \( A \) can be identified (as an object of \( \mathcal{C} \)) with

\[
\text{Bar}^{(k)}(\text{Free}(C))^\vee \simeq (\Sigma^k C)^\vee \simeq \Omega^k(C^\vee).
\]

We now explain the relationship between Propositions 5.2.5.33 and 5.2.5.1.

Lemma 5.2.5.36. Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category. Then for each integer \( k \geq 1 \), there exist canonical homotopy equivalences

\[
\text{Pair}^{(k)}(A, B^{\text{rev}}) \simeq \text{Pair}^{(k)}(A, B)
\]

which depend functorially on \( A, B \in \text{Alg}_{/k}^{\text{aug}}(\mathcal{C}) \).

Proof. Let us identify \( E_\infty^{\circ} \) with the colimit of the sequence

\[
E_1^\circ \to E_2^\circ \to E_3^\circ \to \cdots
\]
as in Remark 5.2.5.25 and regard \( \mathcal{C} \) as an \( E_\infty \)-monoidal \( \infty \)-category. Applying Construction 5.2.5.27 in the case \( k = \infty \) (or passing to the limit for finite values of \( k \)) we obtain an \( E_\infty \)-monoidal duality pairing

\[
\text{Dual}(\mathcal{C})^\circ \to \mathcal{C}^\circ \times_{E_\infty} (\mathcal{C}^{\text{rev}})^\circ.
\]

For every map of \( \infty \)-operads \( f : O^\circ \to E_\infty^\circ \), we obtain an induced pairing \( \text{Alg}_{/\infty}(\mathcal{C})^{\text{op}} \times \text{Alg}_{/\infty}(\mathcal{C})^{\text{op}} \to S \). Taking \( f \) to be the tautological inclusion \( \rho_k : E_k^\circ \hookrightarrow E_\infty^\circ \), we obtain the functor \( (A, B) \mapsto \text{Pair}^{(k)}(A, B) \) (see Variant 5.2.5.30). To complete the proof, it will suffice to show that \( \rho_k \) and \( \rho_{k+1} \circ t \) are homotopic (as morphisms of \( \infty \)-operads from \( E_k^\circ \) to \( E_\infty^\circ \)). This is automatic, since \( E_\infty^\circ \) is a final object of the \( \infty \)-category of \( \infty \)-operads (Corollary 5.1.1.5).

\[\square\]
Remarks 5.2.5.37. In the situation of Lemma 5.2.5.36, it is not necessary to assume that \( \mathcal{C} \) is symmetric monoidal: the analogous result holds more generally if we assume only that \( \mathcal{C} \) is \( E_{k+1} \)-monoidal. To adapt the proof given above, it is only necessary to know that the inclusion maps \( \iota, \iota' : E_k^p \to E_{k+1}^\otimes \) are homotopic to one another. To prove this, let \( G = \Sigma_{k+1} \times \{ \pm 1 \}^{k+1} \) be as in Remark 5.2.5.19, so that each element \( g \in G \) determines an automorphism \( \rho_g \) of \( E_{k+1}^\otimes \). We now observe that there is a unique element \( g \in G \) whose image in \( O(k+1) \) belongs to the identity component \( SO(k+1) \) and which satisfies \( \rho_g \circ \iota = \iota' \). It will therefore suffice to show that \( \rho_g \) is homotopic to the identity, which follows from the fact that the action of \( G \) on \( E_{k+1}^\otimes \) factors through an action of \( O(k+1) \). Note that this argument yields homotopy equivalences

\[
\text{Pair}^{(k)}(A, B^\rev) \simeq \text{Pair}'^{(k)}(A, B)
\]

which depend functorially on \( A, B \in \text{Alg}_{E_k}(\mathcal{C}) \) but are not truly canonical (they depend on a choice of path from \( g \) to the identity in the group \( SO(k+1) \)).

Lemma 5.2.5.36 motivates the following:

Definition 5.2.5.38. Let \( \mathcal{C} \) be an \( E_k \)-monoidal \( \infty \)-category for \( 0 < k < \infty \). Suppose we are given augmented algebra objects \( A \in \text{Alg}_{E_k}(\mathcal{C}) \) and \( B \in \text{Alg}_{E_k}(\mathcal{C}^\rev) \) and an element \( \eta \in \text{Pair}^{(k)}(A, B^\rev) \). We will say that \( \eta \) exhibits \( B \) as a left Koszul dual of \( A \) if, for every augmented algebra \( B' \in \text{Alg}_{E_k}(\mathcal{C}^\rev) \), evaluation on \( \eta \) induces a homotopy equivalence

\[
\text{Map}_{\text{Alg}_{E_k}(\mathcal{C}^\rev)}(B', B) \to \text{Pair}^{(k)}(A, B').
\]

We will say that \( \eta \) exhibits \( A \) as a right Koszul dual of \( B \) if, for every object \( A' \in \text{Alg}_{E_k}(\mathcal{C}) \), evaluation on \( \eta \) induces a homotopy equivalence

\[
\text{Map}_{\text{Alg}_{E_k}(\mathcal{C})}(A', A) \to \text{Pair}^{(k)}(A', B).
\]

In the special case where the monoidal structure on \( \mathcal{C} \) is symmetric, Definition 5.2.5.38 reduces to the definition given at the beginning of this section (this follows immediately from Lemma 5.2.5.36).

Proof of Proposition 5.2.5.1. In the case \( k = 0 \), the desired result follows from Example 5.2.5.31. For \( k > 0 \), combine Lemma 5.2.5.36 with Proposition 5.2.5.33. 

5.2.6 Iterated Loop Spaces

Let \( X \) be a topological space equipped with a base point \( * \) and let \( k \geq 0 \) be an integer. We let \( \Omega^k X \) denote the \( k \)-fold loop space of \( X \), which we will identify with the space of maps \( f : [-1,1]^k \to X \) which carry the boundary \( \partial[-1,1]^k \) to the base point of \( X \). Then \( \Omega^k X \) is equipped with an action of the topological operad \( \mathcal{E}_k \): given a collection of rectilinear embeddings \( \gamma = \{ \gamma_i : \square^k \to \square^k \}_{1 \leq i \leq n} \) with disjoint images, there is an induced map

\[
\prod_{1 \leq i \leq n} \Omega^k X \to \Omega^k X
\]

\[
(f_1, \ldots, f_n) \mapsto f
\]

\[
f(y) = \begin{cases} 
  f_i(z) & \text{if } y = \gamma_i(z) \text{ for some } i \\
  * & \text{otherwise}.
\end{cases}
\]

It follows that the Kan complex \( \text{Sing}* \Omega^k(X) \) is equipped with an action of the simplicial operad \( \text{Sing}^\mathcal{E}_k \). This action is encoded by a map

\[
\theta_X : \text{Sing}^\mathcal{E}_k^\otimes \to \text{Kan},
\]
where $\mathcal{K}\text{an}$ denotes the (simplicial) category of Kan complexes. Restricting our attention to the case where $X = |K|$, where $K$ is a (pointed) Kan complex, we obtain a simplicial functor

$$\mathcal{K}\text{an}_{\times} \times \text{Sing}^d E_k^\otimes \rightarrow \mathcal{K}\text{an}.$$ 

$$(K, (n)) \mapsto (\text{Sing}_\bullet \Omega^k |K|)^n.$$ 

Passing to nerves and using the equivalence $N(\mathcal{K}\text{an}_{\times}) \rightarrow \mathcal{S}_*$, we obtain a functor

$$S_* \times E_k^\otimes \rightarrow \mathcal{S}.$$ 

For every pointed Kan complex $K$, the resulting map $E_k^\otimes \rightarrow \mathcal{S}$ is evidently an $E_k$-monoid object of $\mathcal{S}$ (in the sense of Definition 2.4.2.1). Consequently, $N(\theta)$ is adjoint to a functor $\beta_k : S_* \rightarrow \text{Mon}_{E_k}(\mathcal{S})$. We will refer to $E_k$-monoid objects of $\mathcal{S}$ simply as $E_k$-spaces, and $\text{Mon}_{E_k}(\mathcal{S})$ as the \textit{∞-category of $E_k$-spaces}. The functor $\beta_k$ implements the observation that for every pointed space $X$, the $k$-fold loop space of $X$ is an $E_k$-space. This observation has a converse: the functor $\beta$ is \textit{almost} an equivalence of $\infty$-categories. However, it fails to be an equivalence for two reasons:

(a) If $X$ is a pointed space, then the $k$-fold loop space $\Omega^k X$ contains no information about the homotopy groups $\pi_i X$ for $i < k$. More precisely, if $k > 0$ and $f : X \rightarrow Y$ is a map of pointed spaces which induces isomorphisms $\pi_i X \rightarrow \pi_i Y$ for $i \geq k$, then the induced map $\Omega^k X \rightarrow \Omega^k Y$ is a weak homotopy equivalence of spaces. Consequently, the functor $\beta_k : S_* \rightarrow \text{Mon}_{E_k}(\mathcal{S})$ fails to be conservative. To correct this problem, we need to restrict our attention to $k$-\textit{connective} spaces: that is, pointed spaces $X$ such that $\pi_i X \simeq *$ for $i < k$; for such spaces, there is no information about low-dimensional homotopy groups to be lost.

(b) Suppose that $k > 0$ and let $Y \in \text{Mon}_{E_k}(\mathcal{S})$; we will abuse notation by identifying $Y$ with the space $Y((1))$. Then $Y$ carries an action of the $\infty$-operad $E_1$: in particular, there is a multiplication map $Y \times Y \rightarrow Y$ which is unital and associative up to homotopy. This multiplication endows the set of connected components $\pi_0 Y$ with the structure of a monoid (which is commutative if $k > 1$). If $Y \simeq \Omega^k X$ lies in the image of the functor $\beta$, then we have a canonical isomorphism $\pi_0 Y \simeq \pi_k X$ (compatible with the monoid structures on each side). In particular, we deduce that the monoid $\pi_0 Y$ is actually a group (that is, $Y$ is \textit{grouplike} in the sense of Definition 5.2.6.6 below).

Remark 5.2.6.1. In the case $k = 0$, issues (a) and (b) do not arise: in fact, we have canonical equivalences of $\infty$-categories

$$S_* \simeq \text{Alg}_{E_0}(\mathcal{S}) \simeq \text{Mon}_{E_0}(\mathcal{S})$$

(here we regard $\mathcal{S}$ as endowed with the Cartesian monoidal structure). The first equivalence results from Proposition 2.1.3.9, and the second from Proposition 2.4.2.5; the composition of these equivalences agrees with the map $\beta$ defined above. For this reason, we will confine our attention to the case $k > 0$ in what follows.

We first introduce some terminology which is motivated by the above discussion.

Definition 5.2.6.2. Let $\mathcal{C}$ be an $\infty$-category which admits finite products and let $G$ be an associative monoid object of $\mathcal{C}$. Let $m : G \times G \rightarrow G$ the multiplication maps, and let $p_1, p_2 : G \times G \rightarrow G$ be the projection maps onto the first and second factors, respectively. We will say that $G$ is \textit{grouplike} if the maps

$$(p_1, m) : G \times G \rightarrow G \times G \quad (m, p_2) : G \times G \rightarrow G \times G$$

are equivalences. We let $\text{Mon}^{\text{gp}}_{\text{Ass}}(\mathcal{C})$ denote the full subcategory of $\text{Mon}_{\text{Ass}}(\mathcal{C})$ spanned by the grouplike monoid objects of $\mathcal{C}$.
5.2. BAR CONSTRUCTIONS AND KOSZUL DUALITY

Example 5.2.6.3. Let $G$ be a monoid, which we can regard as an associative monoid object of the ∞-category $N(\text{Set})$ of sets. Then $G$ is grouplike if and only if the constructions

$$(x,y) \mapsto (x,xy) \quad (x,y) \mapsto (xy,y)$$

determine bijections from $G$ to itself. It is not hard to see that this condition holds if and only if $G$ is a group.

Example 5.2.6.4. Let $G$ be an associative monoid object of the ∞-category $S$ of spaces. If $G$ is grouplike, then $\pi_0 G$ is a grouplike associative monoid object of the ∞-category $N(\text{Set})$ and therefore a group. Conversely, suppose that $\pi_0 G$ is a group. For each point $x \in G$ determining a connected component $[x] \in \pi_0 G$, we can choose another point $y \in G$ satisfying $[y] = [x]^{-1}$. Then left multiplication by $x$ induces a homotopy equivalence $G \to G$ (with homotopy inverse given by left multiplication by $y$). Since this condition holds for every $x \in G$, it follows that the map $(p_1, m) : G \times G \to G \times G$ is also a homotopy equivalence (since we can check on homotopy fibers of $p_1$). A similar argument shows that the map $(m, p_2) : G \times G \to G \times G$ is a homotopy equivalence.

Remark 5.2.6.5. Let $\mathcal{C}$ be an ∞-category which admits finite products. Composition with the functor $\text{Cut} : N(\Delta)^{op} \to \text{Ass}^\otimes$ of Construction 4.1.2.5 determines a functor $\theta : \text{Mon}_{\text{Ass}}(\mathcal{C}) \to \text{Mon}(\mathcal{C}) \subseteq \text{Fun}(N(\Delta)^{op}, \mathcal{C})$. An associative monoid object $G \in \text{Mon}_{\text{Ass}}(\mathcal{C})$ is grouplike if and only if the simplicial object $\theta(G)$ is a groupoid object of $\mathcal{C}$, in the sense of §T.6.1.2.

Definition 5.2.6.6. Let $\mathcal{C}$ be an ∞-category which admits finite products. We will say that an $E_1$-monoid object $G : E_1^{op} \to \mathcal{C}$ is grouplike if it belongs to the essential image of $\text{Mon}_{E_1}^{gp}(\mathcal{X})$ under the equivalence of ∞-categories $\text{Mon}_{\text{Ass}}(\mathcal{X}) \to \text{Mon}_{E_1}(\mathcal{X})$ determined by the equivalence $E_1^{ops} \to \text{Ass}^\otimes$. We let $\text{Mon}_{E_1}^{gp}(\mathcal{X}) \subseteq \text{Mon}_{E_1}(\mathcal{X})$ denote the full subcategory spanned by the grouplike $E_1$-monoid objects of $\mathcal{X}$.

Remark 5.2.6.7. Let $\mathcal{C}$ be an ∞-category which admits finite products and let $G$ be an $E_k$-monoid object of $\mathcal{C}$ for $2 \leq k \leq \infty$. Then the multiplication map $m : G \times G \to G$ is commutative up to homotopy. Consequently, $G$ is grouplike if and only if the map $(m, p_2) : G \times G \to G \times G$ is an equivalence in $\mathcal{C}$.

Remark 5.2.6.8. In the situation of Definition 5.2.6.6, the condition that $X$ is grouplike does not depend on which of the natural embeddings $E_1^{op} \to E_k^{op}$ is chosen.

Remark 5.2.6.9. Let $1 \leq k \leq \infty$. Then the full subcategory $\text{Mon}_{E_k}^{gp}(S) \subseteq \text{Mon}_{E_k}(S)$ is closed under small colimits. To prove this, we note that $\text{Mon}_{E_k}^{gp}(S)$ is given by the inverse image of $\text{Mon}_{E_k}^{gp}(N(\text{Set}))$ under the colimit-preserving functor

$$\pi_0 : \text{Mon}_{E_k}(S) \to \text{Mon}_{E_k}(N(\text{Set})).$$

It will therefore suffice to show that the category of (abelian) groups is closed under small colimits in the category of (commutative) monoids, which is clear.

The main goal of this section is to prove the following:

Theorem 5.2.6.10 (Boardman-Vogt, May). Let $0 < k < \infty$, and let $S_{\geq k}^\geq$ denote the full subcategory of $S_{\geq k}^\geq$ spanned by the $k$-connective spaces. Then:

1. The functor $\beta_k : S_{\geq k} \to \text{Mon}_{E_k}(S)$ is fully faithful when restricted to $S_{\geq k}^{\geq k}$.

2. The essential image of $\beta_k|_{S_{\geq k}^{\geq k}}$ is the full subcategory $\text{Mon}_{E_k}^{gp}(S) \subseteq \text{Mon}_{E_k}(S)$ spanned by the grouplike $E_k$-spaces.

3. The equivalence $S_{\geq k}^{\geq k} \to \text{Mon}_{E_k}^{gp}(S)$ admits an explicit homotopy inverse, given by the $k$-fold bar construction of §5.2.3.
We will prove Theorem 5.2.6.10 in two steps. First, we show that for any ∞-topos $\mathcal{X}$, the $k$-fold bar construction induces an equivalence from grouplike $\mathbb{E}_k$-monoid objects of $\mathcal{X}$ to pointed $k$-connective objects of $\mathcal{X}$ (Theorem 5.2.6.15). We then show that in the special case $\mathcal{X} = \mathcal{S}$, the bar construction is homotopy inverse to $\beta_k$. We begin with some general considerations.

**Notation 5.2.6.11.** Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}_*$ be the ∞-category of pointed objects of $\mathcal{X}$. We will regard $\mathcal{X}$ and $\mathcal{X}_*$ as equipped with the Cartesian symmetric monoidal structures. Let $k > 0$ be an integer, and observe that the forgetful functors

$$\text{Alg}_{\mathbb{E}_k}(\mathcal{X}_*) \to \text{Alg}_{\mathbb{E}_k}(\mathcal{X}) \quad \text{Alg}_{\mathbb{E}_k}(\mathcal{X}_*)^{\text{op}} \to \mathcal{X}_*^{\text{op}}$$

are equivalences of ∞-categories. Since $\mathcal{X}$ admits geometric realizations of simplicial objects, we can consider the $k$-fold bar construction

$$\text{Mon}_{\mathbb{E}_k}(\mathcal{X}) \simeq \text{Alg}_{\mathbb{E}_k}(\mathcal{X}_*) \xrightarrow{\text{Bar}^{(k)}} \text{Alg}_{\mathbb{E}_k}(\mathcal{X}_*)^{\text{op}} \simeq \mathcal{X}_*.$$ 

Since $\mathcal{X}$ admits totalizations of cosimplicial objects, the $k$-fold bar construction admits a right adjoint, given the $k$-fold cobar construction

$$\mathcal{X}_* \simeq \text{Alg}_{\mathbb{E}_k}(\mathcal{X}_*)^{\text{op}} \xrightarrow{\text{Cobar}^{(k)}} \text{Alg}_{\mathbb{E}_k}(\mathcal{X}_*) \simeq \text{Mon}_{\mathbb{E}_k}(\mathcal{X}).$$

In what follows, we will abuse notation by denoting these adjoint functors by

$$\text{Bar}^{(k)} : \text{Mon}_{\mathbb{E}_k}(\mathcal{X}) \to \mathcal{X}_* \quad \text{Cobar}^{(k)} : \mathcal{X}_* \to \text{Mon}_{\mathbb{E}_k}(\mathcal{X}).$$

**Remark 5.2.6.12.** Let $\mathcal{X}$ be an ∞-topos and let $0 < k < \infty$. Using Examples 5.2.2.4 and 5.2.3.14, we see that the the composite functor

$$\mathcal{X}_* \xrightarrow{\text{Cobar}^{(k)}} \text{Mon}_{\mathbb{E}_k}(\mathcal{X}) \to \mathcal{X}$$

is given by $X \mapsto \Omega^k X$.

**Example 5.2.6.13.** When $k = 1$, we can identify $\text{Mon}_{\mathbb{E}_1}(\mathcal{X})$ with the ∞-category $\text{Mon}(\mathcal{X}) \subseteq \text{Fun}(N(\Delta)^{op}, \mathcal{X})$ of monoid objects of $\mathcal{X}$. Under this equivalence, the bar construction $\text{Bar}^{(1)}$ carries a monoid $G_*$ to its geometric realization $|G_*|$, regarded as a pointed object of $\mathcal{X}$ via the augmentation map $G_0 \to |G_*|$. Since $\mathcal{X}$ is an ∞-topos, this construction determines a fully faithful embedding from grouplike monoid objects of $\mathcal{X}$ (see Remark 5.2.6.5) to the full subcategory of $\mathcal{X}_*$ spanned by those pointed objects $X$ for which the map $* \to X$ is an effective epimorphism.

**Example 5.2.6.14.** Let $G$ be a discrete group, regarded as a grouplike $\mathbb{E}_1$-monoid object of $N(\text{Set}) \subseteq \mathcal{S}$. Then $\text{Bar}^{(1)}(G)$ can be identified with the usual classifying space $BG$ (regarded as a pointed space).

If $\mathcal{X}$ is an ∞-topos, we let $\mathcal{X}_*$ denote the ∞-category of pointed objects of $\mathcal{X}$. For each integer $a \geq 0$, we let $\mathcal{X}_*^{\geq a}$ denote the full subcategory of $\mathcal{X}_*$ spanned by the $a$-connective pointed objects. We regard $\mathcal{X}_*^{\geq a}$ as endowed with the Cartesian symmetric monoidal structure. Note that the unit object of $\mathcal{X}_*^{\geq a}$ is its final object and that $\mathcal{X}_*^{\geq a}$ admits geometric realizations of simplicial objects, so that the formalism of §5.2.3 can be applied.

**Theorem 5.2.6.15.** Let $\mathcal{X}$ be an ∞-topos. For each $k > 0$, the $k$-fold cobar construction

$$\text{Cobar}^{(k)} : \mathcal{X}_* \to \text{Mon}_{\mathbb{E}_k}(\mathcal{X})$$

restricts to an equivalence of ∞-categories $\mathcal{X}_*^{\geq k} \to \text{Mon}_{\mathbb{E}_k}^{\text{op}}(\mathcal{X})$.

**Lemma 5.2.6.16.** Let $\mathcal{X}$ be an ∞-topos and let $G$ be a monoid object of $\mathcal{X}$. If $G$ is 1-connective, then $G$ is grouplike.
Preserves sifted colimits. This follows from Proposition 2.4.2.5, Proposition 3.2.3.1, and Lemma 3.2.2.6.

Proof. Since $X$ is an ∞-topos, we can choose a small ∞-category $C$ and a fully faithful embedding $f_* : X \to \mathcal{P}(C)$ with a left exact left adjoint $f^* : \mathcal{P}(C) \to X$. Then $f_*G$ is a monoid object of $\mathcal{P}(C)$, so that $\tau_{\leq 0} f_*G$ inherits the structure of a monoid object of $\tau_{\leq 0} \mathcal{P}(C)$. Let $H$ denote the fiber of the truncation map $(f_*G) \to \tau_{\leq 0} f_*G$. Then $f^* H$ can be identified with the fiber of the truncation map

$$G \simeq f^* f_* G \to f^* \tau_{\leq 0} f_* G \simeq \tau_{\leq 0} f^* f_* G \simeq \tau_{\leq 0} G \simeq 1,$$

and is therefore equivalent to $G$ as a monoid object of $X$. To prove that $G$ is grouplike, it will suffice to prove that $H$ is grouplike. We may therefore replace $X$ by $\mathcal{P}(C)$ (and $G$ by $H$) and thereby reduce to the case where $X$ is an ∞-topos of presheaves. In this case, the monoid object $G$ is grouplike if and only if for each object $C \in \mathcal{C}$, the evaluation $G(C)$ is grouplike when regarded as a monoid object of $S$. We may therefore assume without loss of generality that $X = S$, in which case the desired result follows immediately from the characterization given in Example 5.2.6.4.

**Remark 5.2.6.17.** Let $k$ and $k'$ be positive integers. It follows from Remark 5.2.6.12 that an object $X \in \mathcal{X}_k$ belongs to $\mathcal{X}_k^{k+k'}$ if and only if $\text{Cobar}^{(k)}(X)$ belongs to the full subcategory $\text{Mon}_{\mathcal{E}}(\mathcal{X}_k^{k'}) \subseteq \text{Mon}_{\mathcal{E}}(\mathcal{X}_k) \simeq \text{Mon}_{\mathcal{E}}(\mathcal{X})$. Consequently, if Theorem 5.2.6.15 holds for the integer $k$, then the cobar construction $\text{Cobar}^{(k)}$ induces an equivalence of ∞-categories

$$\mathcal{X}_k^{k+k'} \to \text{Mon}_{\mathcal{E}}(\mathcal{X}_k^{k'}).$$

**Proof of Theorem 5.2.6.15.** In the case $k = 1$, the desired result follows from Example 5.2.6.13. We treat the general case using induction on $k$. If $k \geq 2$, we can write $k = a + b$ for $a, b \geq 1$. Using Remark 5.2.3.14, we see that the $k$-fold cobar construction $\text{Cobar}^{(k)}$ factors as a composition

$$\mathcal{X}_* \xrightarrow{\text{Cobar}^{(a)}} \text{Mon}_{\mathcal{E}}(\mathcal{X}_*) \xrightarrow{\text{Cobar}^{(b)}} \text{Mon}_{\mathcal{E}}(\text{Mon}_{\mathcal{E}}(\mathcal{X}_*)) \simeq \text{Mon}_{\mathcal{E}}(\mathcal{X}_*) \simeq \text{Mon}_{\mathcal{E}}(\mathcal{X}).$$

The desired result now follows from the inductive hypothesis together with Remark 5.2.6.17. □

Let us now extract some consequences of Theorem 5.2.6.15.

**Corollary 5.2.6.18.** For any ∞-topos $X$, the loop functor $\Omega^k : \mathcal{E}_k \to S$ is conservative and preserves sifted colimits.

**Proof.** Using Theorem 5.2.6.15 and Remark 5.2.6.12, we may reduce to the problem of showing that the forgetful functor $\theta : \text{Mon}_{\mathcal{E}}^\mathcal{P}(S) \to S$ is conservative and preserves sifted colimits. Since $\text{Mon}_{\mathcal{E}}^\mathcal{P}(S)$ is stable under colimits in $\text{Mon}_{\mathcal{E}}(S)$, it suffices to show that the forgetful functor $\text{Mon}_{\mathcal{E}}(S) \to S$ is conservative and preserves sifted colimits. This follows from Proposition 2.4.2.5, Proposition 3.2.3.1, and Lemma 3.2.2.6. □

We note that the loop functor $\Omega : \mathcal{E}_1 \to S$ is corepresentable by the 1-sphere $S^1 \in \mathcal{E}_1$. It follows from Corollary 5.2.6.18 that $S^1$ is a compact projective object of $\mathcal{E}_1$. Since the collection of compact projective objects of $\mathcal{E}_1$ is stable under finite coproducts, we deduce the following:

**Corollary 5.2.6.19.** Let $F$ be a finitely generated free group, and $BF$ its classifying space. Then $BF$ is a compact projective object of $\mathcal{E}_1$.

For each $n \geq 0$, let $F(n)$ denote the free group on $n$ generators, and $BF(n)$ a classifying space for $F(n)$. Let $\mathcal{F}$ denote the full subcategory of the category of groups spanned by the objects $\{ F(n) \}_{n \geq 0}$. We observe that the construction $F(n) \to BF(n)$ determines a fully faithful embedding $\iota : \mathcal{N}(\mathcal{F}) \to \mathcal{E}_1$. Let $\mathcal{P}_\Sigma(\mathcal{N}(\mathcal{F}))$ be defined as in §5.5.8 (that is, $\mathcal{P}_\Sigma(\mathcal{N}(\mathcal{F}))$ is the ∞-category freely generated by $\mathcal{N}(\mathcal{F})$ under sifted colimits).
Remark 5.2.6.20. According to Corollary T.5.5.9.3, the $\infty$-category $\mathcal{P}(\mathcal{N}(\mathcal{F}))$ is equivalent to the underlying $\infty$-category of the simplicial model category $\mathcal{A}$ of simplicial groups.

It follows from Proposition T.5.5.8.15 that the fully faithful embedding $i$ is equivalent to a composition

$$\mathcal{N}(\mathcal{F}) \xrightarrow{j} \mathcal{P}(\mathcal{N}(\mathcal{F})) \xrightarrow{F} S^\geq_1,$$

where $F$ is a functor which preserves sifted colimits (moreover, the functor $F$ is essentially unique).

Corollary 5.2.6.21. The functor $F : \mathcal{P}(\mathcal{N}(\mathcal{F})) \to S^\geq_1$ is an equivalence of $\infty$-categories.

Remark 5.2.6.22. Combining Corollary 5.2.6.21 and Remark 5.2.6.20, we recover the following classical fact: the homotopy theory of pointed connected spaces is equivalent to the homotopy theory of simplicial groups. See [57] for an explicit combinatorial version of this equivalence.

Proof of Corollary 5.2.6.21. Since $i : \mathcal{N}(\mathcal{F}) \to S^\geq_1$ is fully faithful and its essential image consists of compact projective objects (Corollary 5.2.6.19), Proposition T.5.5.8.22 implies that $F$ is fully faithful. We observe that the functor $i$ preserves finite coproducts, so that $F$ preserves small colimits by virtue of Proposition T.5.5.8.15. Using Corollary T.5.5.2.9, we deduce that $F$ admits a right adjoint $G$. Since $F$ is fully faithful, $G$ is a colocalization functor; to complete the proof, it will suffice to show that $G$ is conservative.

Let $f : X \to Y$ be a morphism in $S^\geq_1$ such that $G(f)$ is an equivalence; we wish to prove that $f$ is an equivalence. Let $Z$ be the free group on one generator, and $jZ$ its image in $\mathcal{P}(\mathcal{N}(\mathcal{F}))$. Then $f$ induces a homotopy equivalence

$$\text{Map}_{S^\geq_1}(S^1, X) \simeq \text{Map}_{\mathcal{P}(\mathcal{N}(\mathcal{F}))}(jZ, GX) \to \text{Map}_{\mathcal{P}(\mathcal{N}(\mathcal{F}))}(jZ, GY) \simeq \text{Map}_{S^\geq_1}(S^1, Y).$$

It follows that $\Omega(f) : \Omega X \to \Omega Y$ is a homotopy equivalence, so that $f$ is a homotopy equivalence by virtue of Corollary 5.2.6.18.

Theorem 5.2.6.10 is an immediate consequence of Theorem 5.2.6.15 together with the following:

Proposition 5.2.6.23. For each integer $k > 0$, the functors $\beta_k, \text{Cobar}^{(k)} : S_* \to \text{Mon}_{S_k}(S)$ are equivalent to one another.

Remark 5.2.6.24. Suppose we are given a pair of nonnegative integers $k$ and $k'$. The bifunctor of $\infty$-operads $E_k \otimes E_{k'} \to E_{k+k'}$ determines a map

$$\rho : \text{Mon}_{S_{k+k'}}(S) \to \text{Mon}_{S_k}(\text{Mon}_{S_{k'}}(S)),$$

which is an equivalence of $\infty$-categories by virtue of Theorem 5.1.2.2. Let $K$ be a pointed Kan complex. Then the counit map

$$\text{Sing}_* (\Omega^k | \text{Sing}_* (\Omega^{k'} | K)) \to \text{Sing}_* (\Omega^{k+k'} | K)$$

underlies an equivalence in the $\infty$-category $\text{Mon}_{S_k}(\text{Mon}_{S_{k'}}(S))$, which depends functorially on $K$. In other words, the diagram of $\infty$-categories

$$\begin{array}{ccc}
S_* & \xrightarrow{\beta_k} & \text{Mon}_{S_k}(S_*) \\
\downarrow{\beta_{k+k'}} & & \downarrow{\beta_{k'}} \\
\text{Mon}_{S_{k+k'}}(S_*) & \xrightarrow{\rho} & \text{Mon}_{S_k}(\text{Mon}_{S_{k'}}(S_*))
\end{array}$$

commutes up to homotopy.
Proof of Proposition 5.2.6.23. Using Remarks 5.2.6.24 and 5.2.3.14, we can reduce to the case $k = 1$. Let $G : \text{Mon}_{S}(\mathcal{S}) \rightarrow \mathcal{S}$ denote the forgetful functor, so that $G \circ \beta_{1} \text{ and } G \circ \text{Cobar}^{(1)}$ are both equivalent to the functor $\Omega : \mathcal{S}_{\ast} \rightarrow \mathcal{S}$. It follows that for any pointed space $X$ with base point component $X_{\ast}$, the canonical maps

$$\beta_{1}(X_{\ast}) \rightarrow \beta_{1}X \quad \text{Cobar}^{(1)}X_{\ast} \rightarrow \text{Cobar}^{(1)}X$$

are equivalences. It will therefore suffice to show that the functors $\beta_{1}|_{S_{\geq 1}}$ and $\text{Cobar}^{(1)}|_{S_{\geq 1}}$ are equivalent. Using Corollary 5.2.6.18, we see that the functors $\beta_{1}|_{S_{\geq 1}}$ and $\text{Cobar}^{(1)}|_{S_{\geq 1}}$ preserve sifted colimits. It will therefore suffice to show that the functors $\beta_{1}$ and $\text{Cobar}^{(1)}$ are equivalent when restricted to spaces of the form $BF$, where $F$ is a finitely generated free group. We have canonical equivalences

$$\beta_{1}(BF) \simeq \pi_{1}(BF) \simeq F \simeq \text{Cobar}^{(1)} \text{Bar}^{(1)}F \simeq \text{Cobar}^{(1)}BF,$$

since the bar construction $\text{Bar}^{(1)}(F)$ can be functorially identified with the classifying space $BF$ (Example 5.2.6.14).

Remark 5.2.6.25. Let $K$ be a pointed space. Then the $k$-fold loop space $\Omega^{k}K$ can be endowed with two \textit{a priori} different $E_{k}$-structures: one coming from the geometric structure of the little cubes operads, and the second coming from the identification of $\Omega^{k}K$ with the $k$-fold cobar construction of $\Sect_{k}$. Proposition 5.2.6.23 asserts that these two structures are equivalent to one another. However, our proof is somewhat unsatisfying: rather than directly exhibiting an equivalence of $E_{k}$-spaces, we instead argued that they cannot help but to be equivalent by virtue of all of the naturality properties that both constructions enjoy. Let us briefly sketch a construction which relates the functors $\beta_{k}$ and $\text{Cobar}^{(k)}$ more directly.

Fix a pointed topological space $X$. Let $C = \Box^{k}$ be an open $k$-dimensional cube and let $C^{+}$ denote its one-point compactification. We let $\text{Map}(C, X)$ denote the space of all maps from $C$ to $X$ (which is homotopy equivalent to $X$), and $\text{Map}_{\ast}(C^{+}, X)$ the space of all pointed maps from $C^{+}$ into $X$ (which is homotopy equivalent to the $k$-fold loop space $\Omega^{k}(X)$). There is an evident inclusion map $\rho_{C} : \text{Map}_{\ast}(C^{+}, X) \hookrightarrow \text{Map}(C, X)$. Given a collection of rectilinear embeddings

$$\gamma_{1} : C_{1} \hookrightarrow C \quad \cdots \quad \gamma_{n} : C_{n} \hookrightarrow C$$

having disjoint images, we can associate a map of pointed spaces $\delta : C^{+} \rightarrow C_{1}^{+} \lor C_{2}^{+} \lor \cdots \lor C_{n}^{+}$. We have a commutative diagram

$$\begin{array}{c}
\Pi_{1 \leq i \leq n} \text{Map}_{\ast}(C_{i}^{+}, X) \\
\downarrow \\
\text{Map}_{\ast}(C, X)
\end{array} \xrightarrow{\rho_{C}} \begin{array}{c}
\Pi_{1 \leq i \leq n} \text{Map}(C_{i}, X) \\
\uparrow \\
\text{Map}(C, X)
\end{array}
$$

where the vertical maps are given by composition with $\delta$ and the $\gamma_{i}$. One can show that these commutative diagrams exhibit $\rho_{C}$ as an $E_{k}$-algebra in the twisted arrow category of spaces. Taking $X = |K|$ for some Kan complex $K$, we obtain an object of $\text{Alg}_{E_{k}}(\text{TwArr}(S))$ whose image in $\text{Alg}_{E_{k}}(S)$ agrees with $\beta_{k}K$ and whose image in $\text{Alg}_{E_{k}}(S^{op}) \simeq S$ agrees with $K$. This determines a canonical map $\beta_{k}K \rightarrow \text{Cobar}^{(k)}K$, which can be shown to be an equivalence.

Remark 5.2.6.26. For every integer $k$, the diagram

$$\begin{array}{ccc}
S_{k} & \xrightarrow{\omega} & S_{k} \\
\downarrow \beta_{k+1} & & \downarrow \beta_{k} \\
\text{Mon}_{E_{k+1}}(S) & \xrightarrow{\beta_{k}} & \text{Mon}_{E_{k}}(S)
\end{array}$$
commutes up to homotopy, where the lower vertical map is induced by the inclusion of \( \infty \)-operads \( \mathbb{E}_k \hookrightarrow \mathbb{E}_{k+1} \). Theorem 5.2.6.10 therefore supplies an identification of the \( \infty \)-category \( \text{Mon}^\text{gp}_{\infty} (\mathcal{S}) \simeq \varprojlim \text{Mon}^\text{gp}_k (\mathcal{S}) \) with the homotopy limit of the tower of \( \infty \)-categories

\[
\cdots \to S^2 \xrightarrow{\varphi} S^1 \xrightarrow{\varphi} S^0,
\]

which is the \( \infty \)-category \( \text{Sp}^cn \) of connective spectra.

**Corollary 5.2.6.27.** Let \( \text{Sp}^cn \) denote the \( \infty \)-category of connective spectra. Then the functor \( \Omega^\infty : \text{Sp}^cn \to \mathcal{S} \) is conservative and preserves sifted colimits.

**Proof.** Using Remark 5.2.6.26, we are reduced to proving that the forgetful functor \( \text{Mon}^\text{gp}_k (\mathcal{S}) \to \mathcal{S} \) is closed under colimits in \( \text{Mon}^\text{gp}_{\infty} (\mathcal{S}) \), we are reduced to proving that the forgetful functor \( \text{Mon}^\text{gp}_k (\mathcal{S}) \to \mathcal{S} \) is conservative and preserves sifted colimits. This follows from Proposition 2.4.2.5, Proposition 3.2.3.1, and Lemma 3.2.2.6.

**Remark 5.2.6.28.** Let \( \mathcal{X} \) be an \( \infty \)-topos, and regard \( \mathcal{X} \) as endowed with the Cartesian symmetric monoidal structure. Theorem 5.2.6.15 guarantees the existence of an equivalence \( \theta : \mathcal{X}^{\geq 1} \simeq \text{Mon}^\text{gp}(\mathcal{X}) \simeq \text{Alg}^\text{gp}(\mathcal{X}) \), where \( \text{Alg}^\text{gp}(\mathcal{X}) \) denotes the essential image of \( \text{Mon}^\text{gp}(\mathcal{X}) \) under the equivalence of \( \infty \)-categories \( \text{Mon}(\mathcal{X}) \simeq \text{Alg}(\mathcal{X}) \) supplied by Propositions 4.1.2.6 and 2.4.2.5. This equivalence fits into a commutative diagram

\[
\begin{array}{ccc}
\text{Fun}(\Delta^1, \mathcal{X}) \times_{\text{Fun}(\{1\}, \mathcal{X})} \mathcal{X}^{\geq 1} & \xrightarrow{\overline{\theta}} & \text{LMod}^\text{gp}(\mathcal{X}) \\
\downarrow & & \downarrow \\
\mathcal{X}^{\geq 1} & \xrightarrow{\theta} & \text{Alg}^\text{gp}(\mathcal{X}),
\end{array}
\]

where \( \text{LMod}^\text{gp}(\mathcal{X}) \) denotes the fiber product \( \text{LMod}(\mathcal{X}) \times_{\text{Alg}(\mathcal{X})} \text{Alg}^\text{gp}(\mathcal{X}) \) and \( \overline{\theta} \) is an equivalence of \( \infty \)-categories. In other words, if \( \mathcal{X} \subseteq \mathcal{X}' \) is a pointed connected object, then there is a canonical equivalence between the \( \infty \)-topos \( \mathcal{X}/\mathcal{X} \) and the \( \infty \)-category \( \text{LMod}_{\theta}(\mathcal{X}) \) of \( \theta(\mathcal{X}) \)-module objects of \( \mathcal{X} \).

To prove this, we let \( \mathcal{D} \) denote the full subcategory of \( \text{Fun}(\Delta^1 \times N(\Delta_+)^{op}, \mathcal{X}) \) spanned by those functors \( F \) with the following properties:

(i) The functor \( F \) is a right Kan extension of its restriction to the full subcategory \( \mathcal{K} \subseteq \Delta^1 \times N(\Delta_+)^{op} \) spanned by the objects \((0, [−1]), (1, [−1]), \) and \((1, [0])\).

(ii) The object \( F(1, [0]) \in \mathcal{X} \) is final.

(iii) The augmentation map \( F(1, [0]) \to F(1, [−1]) \) is an effective epimorphism (equivalently, the object \( F(1, [−1]) \in \mathcal{X} \) is 1-connected).

It follows from Proposition T.4.3.2.15 that the restriction map \( F \mapsto F|\mathcal{K} \) determines a trivial Kan fibration \( \mathcal{D} \rightarrow \text{Fun}(\Delta^1, \mathcal{X}) \times_{\text{Fun}(\{1\}, \mathcal{X})} \mathcal{X}^{\geq 1} \). Recall that we have a canonical equivalence \( \text{LMod}(\mathcal{X}) \simeq \text{LMon}(\mathcal{X}) \) (Propositions 4.2.2.9 and 2.4.2.5). To construct the functor \( \overline{\theta} \), it will suffice to show that the restriction functor \( F \mapsto F|\{1\} \times N(\Delta_+)^{op} \) is a trivial Kan fibration from \( \mathcal{D} \) onto \( \text{LMon}(\mathcal{X}) \times_{\text{Mon}(\mathcal{X})} \text{Mon}^\text{gp}(\mathcal{X}) \), where \( \text{LMon}(\mathcal{X}) \) is defined as in Definition 4.2.2.2. Using Proposition T.4.3.2.8, we see that (i) is equivalent to the following pair of assertions:

(i) The restriction \( F|\{1\} \times N(\Delta_+)^{op} \) is a right Kan extension of its restriction to \( \{1\} \times N(\Delta_+)^{op} \).

(i) The functor \( F \) determines a Cartesian natural transformation from \( F_0 = F|\{0\} \times N(\Delta_+)^{op} \) to \( F_1 = F|\{1\} \times N(\Delta_+)^{op} \).

Assertions (i), (ii), and (iii) are equivalent to requirement that the functor \( F_1 \) belongs to the full subcategory \( \mathcal{C} \subseteq \text{Fun}[N(\Delta_+)^{op}, \mathcal{X}] \) appearing in the proof of Theorem 5.2.6.15. In particular, these conditions guarantee that \( F_1 \) is a colimit diagram. Combining this observation with Theorem T.6.1.3.9 allows us to replace (i) by the following pair of conditions:
(i) The functor $F_0$ is a colimit diagram.

(iii) The restriction $F(|\Delta^1 \times N(\Delta)^{op}|)$ is a Cartesian transformation from $F_0|N(\Delta)^{op}$ to $F_1|N(\Delta)^{op}$.

It follows that $\mathcal{Y}$ can be identified with the full subcategory of $\text{Fun}(\Delta^1, N(\Delta)^{op})$ spanned by those functors $F$ such that $F' = F(|\Delta^1 \times N(\Delta)^{op}|)$ belongs to $\text{LMon}(\mathcal{X}) \times_{\text{Mon}(\mathcal{X})} \text{Mon}_{k}(\mathcal{X})$ and $F$ is a left Kan extension of $F'$. The desired result now follows from Proposition T.4.3.2.15.

**Remark 5.2.6.29.** In the situation of Remark 5.2.6.28, let $X$ be a pointed 1-connected object of the $\infty$-topos $\mathcal{X}$. Under the equivalence $\mathcal{X} \approx \text{LMon}(\mathcal{X})(\mathcal{X})$, the forgetful functor $\text{LMon}_{k}(\mathcal{X}) \to \mathcal{X}$ corresponds to the functor $(Y \to X) \mapsto (Y \times_{X} 1)$ given by passing to the fiber over the base point $\eta : 1 \to X$ (here $1$ denotes the final object of $\mathcal{X}$). It follows that the free module functor $\mathcal{X} \to \text{LMon}(\mathcal{X})(\mathcal{X})$ corresponds to the functor $\mathcal{X} \approx \mathcal{X}/1 \to X/\eta$ given by composition with $\eta$.

### 5.3 Centers and Centralizers

Let $A$ be an associative algebra over a field $k$ with multiplication $m$. Then the cyclic bar complex

$$
\cdots \to A \otimes_k A \otimes_k A \otimes_k A \to A \otimes_k A
$$

provides a resolution of $A$ by free $(A \otimes_k A^{op})$-modules; we will denote this resolution by $P$. The cochain complex $HC^*(A) = \text{Hom}_{A^{op} \otimes A^{op}}(P, A)$ is called the Hochschild cochain complex of the algebra $A$. The cohomologies of the Hochschild cochain complex (which are the Ext-groups $\text{Ext}^i_{A^{op} \otimes A^{op}}(A, A)$) are called the Hochschild cohomology groups of the algebra $A$. A well-known conjecture of Deligne asserts that the Hochschild cochain complex $HC^*(A)$ carries an action of the little 2-cubes operad: in other words, that we can regard $HC^*(A)$ as an $E_2$-algebra object in the $\infty$-category of chain complexes over $k$. This conjecture has subsequently been proven by many authors in many different ways (see, for example, [109], [89], and [142]).

Our first goal in this section is to outline a proof of Deligne’s conjecture using the formalism of $\infty$-operads. The basic strategy (which we will carry out in §5.3.1) can be summarized as follows:

1. Let $\mathcal{C}^{op}$ be an arbitrary presentable symmetric monoidal $\infty$-category, and let $f : A \to B$ be a morphism of $E_k$-algebra objects of $\mathcal{C}$. We will prove that there exists another $E_k$-algebra $\mathfrak{Z}_{E_k}(f)$ of $\mathcal{C}$, which is universal with respect to the existence of a commutative diagram

   $$
   \begin{CD}
   A @>>> \mathfrak{Z}_{E_k}(f) \otimes A \\
   @A{u}AA @VV{f}V \\
   B @= B
   \end{CD}
   $$

   in the $\infty$-category $\text{Alg}_{E_k}(\mathcal{C})$, where $u$ is induced by the unit map $1 \to \mathfrak{Z}_{E_k}(f)$ (Theorem 5.3.1.14). We refer to $\mathfrak{Z}_{E_k}(f)$ as the centralizer of $f$.

2. In the case where $A = B$ and $f$ is the identity map, we will denote $\mathfrak{Z}_{E_k}(A)$ by $\mathfrak{Z}_{E_k}(A)$. We will see that $\mathfrak{Z}_{E_k}(A)$ has the structure of an $E_{k+1}$-algebra object of $\mathcal{C}$. (More generally, the centralizer construction is functorial in the sense that there are canonical maps of $E_k$-algebras $\mathfrak{Z}_{E_k}(f) \otimes \mathfrak{Z}_{E_k}(g) \to \mathfrak{Z}_{E_k}(f \circ g)$; in the special case $f = g = \text{id}_A$ this gives rise to an associative algebra structure on the $E_k$-algebra $\mathfrak{Z}_{E_k}(A)$, which promotes $\mathfrak{Z}_{E_k}(A)$ to an $E_{k+1}$-algebra by Theorem 5.1.2.2.)

3. We will show that the image of $\mathfrak{Z}_{E_k}(f)$ in $\mathcal{C}$ can be identified with a classifying object for morphisms from $A$ to $B$ in the $\infty$-category $\text{Mod}_{E_k}(\mathcal{C})$ (Theorem 5.3.1.30). In the special case where $k = 1$ and $f = \text{id}_A$, we can identify this with a classifying object for endomorphisms of $A$ as an $A$-$A$-bimodule (see Theorem 4.4.1.28), thereby recovering the usual definition of Hochschild cohomology.
Fix an integer \( k \geq 0 \) and let \( \mathcal{C} \to \text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \) be a left adjoint to the forgetful functor. If \( f : A \to B \) is a morphism of \( \mathcal{E}_k \)-algebra objects of \( \mathcal{C} \), then for each \( C \in \mathcal{C} \) we have a canonical fiber sequence

\[
\text{Map}_{\mathcal{C}}(C, \mathcal{Z}(f)) \to \text{Map}_{\text{Alg}_{\mathcal{E}_k}(\mathcal{C})}(\text{Free}(C) \otimes A, B) \to \text{Map}_{\text{Alg}_{\mathcal{E}_k}(\mathcal{C})}(A, B).
\]

Consequently, to understand the structure of \( \mathcal{Z}(f) \) (as an object of \( \mathcal{C} \)), we need to understand the structure of tensor products of the form \( \text{Free}(C) \otimes A \) (as \( \mathcal{E}_k \)-algebra objects of \( \mathcal{C} \)). In §5.3.3, we will address this problem in the special case where \( A = \text{Free}(D) \) is itself freely generated by an object \( D \in \mathcal{C} \). Our main result (Theorem 5.3.3.3) asserts the existence of a pushout square

\[
\begin{array}{ccc}
\text{Free}(C \otimes D \otimes S^{k-1}) & \longrightarrow & \text{Free}(C) \amalg \text{Free}(D) \\
\downarrow & & \downarrow \\
\text{Free}(C \otimes D) & \longrightarrow & \text{Free}(C) \otimes \text{Free}(D)
\end{array}
\]

in \( \text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \). Roughly speaking, this result asserts that \( \text{Free}(C) \otimes \text{Free}(D) \) is freely generated by the objects \( C \) and \( D \), subject to the constraint that they “commute” with respect to all binary operations in the \( \infty \)-operad \( \mathcal{E}_k \).

To every \( \mathcal{E}_k \)-algebra object of a symmetric monoidal \( \infty \)-category \( \mathcal{C} \), one can associate a grouplike \( \mathcal{E}_k \)-space \( A^\times \subseteq \text{Map}_{\mathcal{C}}(1, A) \) which we will refer to as the group of units of \( A \). In §5.3.2, we will study the group of units \( \mathcal{Z}(f)^\times \) of the centralizer of a morphism of \( \mathcal{E}_k \)-algebras \( f : A \to B \). Our main result (Remark 5.3.2.7) implies that that there is a canonical fiber sequence

\[
\mathcal{Z}(f)^\times \to B^\times \to \Omega^{k-1} \text{Map}_{\text{Alg}_{\mathcal{E}_k}(\mathcal{C})}(A, B)
\]

(which admits several deloopings). We can describe the situation informally as follows: the \((k-1)\)-fold delooping \( \text{Bar}^{(k-1)}(B) \) acts on \( B \) and therefore also on the mapping space \( \text{Map}_{\text{Alg}_{\mathcal{E}_k}(\mathcal{C})}(A, B) \), and the stabilizer of the point \( f \in \text{Map}_{\text{Alg}_{\mathcal{E}_k}(\mathcal{C})}(A, B) \) can be identified with the \((k-1)\)-fold delooping \( \text{Bar}^{(k-1)} \mathcal{Z}(f)^\times \).

5.3.1 Centers and Centralizers

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category and let \( \mathcal{M} \) be an \( \infty \)-category which is left-tensored over \( \mathcal{C} \). Suppose we are given an object \( M \in \mathcal{M} \). Recall that an endomorphism object of \( M \) is an object \( \text{End}(M) \in \mathcal{C} \) which represents the functor \( C \mapsto \text{Map}_{\mathcal{M}}(C \otimes M, M) \). In §4.7.2, we saw that if an endomorphism object \( \text{End}(M) \in \mathcal{C} \) exists, then it has the structure of an associative algebra object of \( \mathcal{C} \) and that \( M \) has the structure of an \( \text{End}(M) \)-module. Unfortunately, there are many interesting cases to which we cannot apply this result directly.

Example 5.3.1.1. Let \( k \) be a field, let \( \mathcal{C} \) be (the nerve of) the category of associative \( k \)-algebras (regarded as a monoidal \( \infty \)-category via the tensor product \( \otimes_k \)), and let \( \mathcal{M} = \mathcal{C} \). For any object \( A \in \mathcal{M} \), the center \( Z(A) \) is a commutative \( k \)-algebra which we can identify with an associative algebra object of \( \mathcal{C} \). It is not difficult to see that \( Z(A) \) is universal among those algebra objects of \( \mathcal{C} \) which act on \( A \) (this follows from the observation that any algebra homomorphism \( B \otimes_k A \to A \) which is the identity on \( A \) must carry \( B \) into the center \( Z(A) \)). However, \( Z(A) \) is generally not an endomorphism object of \( A \); for example, the action of \( Z(A) \) on \( A \) usually does not induce a bijection

\[
\text{Hom}_{\mathcal{C}}(k, Z(A)) \to \text{Hom}_{\mathcal{M}}(k \otimes_k A, A) \simeq \text{Hom}_{\mathcal{M}}(A, A).
\]

Our goal in this section is to introduce a generalization of the notion of endomorphism object of \( M \in \mathcal{M} \), which we will refer to as a center of \( M \in \mathcal{M} \) (our terminology is motivated by Example 5.3.1.1). The notions of endomorphism object and center will coincide when the former is defined (see Lemma 5.3.1.11), but centers will exist in much greater generality (Theorem 5.3.1.14). We begin by introducing the closely related notion of the centralizer of a morphism.
5.3. CENTERS AND CENTRALIZERS

Definition 5.3.1.2. Let \( q : \mathcal{C} \to \mathcal{LM} \) be a coCartesian fibration of \( \infty \)-operads, so that \( q \) exhibits \( \mathcal{M} = \mathcal{C}_m \) as left-tensored over the monoidal \( \infty \)-category \( \mathcal{C}_a^\otimes \). Let \( 1 \) denote the unit object of \( \mathcal{C}_a \), and suppose we are given a morphism \( f : 1 \otimes M \to N \) in \( \mathcal{M} \). A centralizer of \( f \) is final object of the \( \infty \)-category

\[
(\mathcal{C}_a)_{1/} \times \mathcal{M}_{1\otimes M/} \mathcal{M}_{1\otimes M/} / N.
\]

We will denote such an object, if it exists, by \( \mathfrak{Z}(f) \). We will refer to \( \mathfrak{Z}(f) \) as the centralizer of the morphism \( f \).

Remark 5.3.1.3. We will generally abuse notation by identifying \( \mathfrak{Z}(f) \) with its image in the \( \infty \)-category \( \mathcal{C} \). By construction, this object is equipped with a map \( \mathfrak{Z}(f) \otimes M \to N \) which fits into a commutative diagram

\[
\begin{array}{ccc}
1 \otimes M & \xrightarrow{f} & N \\
\downarrow & & \\
\mathfrak{Z}(f) \otimes M & \downarrow & \end{array}
\]

Remark 5.3.1.4. In the situation of Definition 5.3.1.2, we can lift \( M \) to an object \( \overline{M} \in \mathcal{LMod}_A(\mathcal{M}) \), where \( A \) is a trivial algebra object of \( \mathcal{C}_a^\otimes \). Then we can identify centralizers for a morphism \( f : M \to N \) with morphism objects \( \text{Mor}_{\mathcal{M}/}(M, N) \) computed in the \( \mathcal{L}\mathcal{M} \)-monoidal \( \infty \)-category \( \mathcal{C}_a^\otimes_{\mathcal{L}\mathcal{M}/} \) (see Definition 4.2.1.28).

Example 5.3.1.5 (Koszul Duality). Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category and let \( k \geq 0 \). Then the \( \infty \)-category \( \text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \) inherits a symmetric monoidal structure: in particular, we can regard \( \mathcal{D} = \text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \) as a monoidal \( \infty \)-category which is left-tensored over itself. If \( \epsilon : A \to 1 \) is an augmented \( \mathcal{E}_k \)-algebra object of \( \mathcal{C} \), then a centralizer of \( \epsilon \) is an \( \mathcal{E}_k \)-algebra \( B \) which is universal among those for which there exists an augmentation \( B \otimes A \to 1 \) which is compatible with \( \epsilon \); in other words, it is a Koszul dual of \( A \), in the sense of §5.2.5.

Definition 5.3.1.6. Let \( q : \mathcal{C} \to \mathcal{LM}^\otimes \) be a coCartesian fibration of \( \infty \)-operads, and let \( M \in \mathcal{M} = \mathcal{C}_m \) be an object. A center of \( M \) is a final object of the fiber product \( \mathcal{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{ M \} \). If such an object exists, we will denote it by \( \mathfrak{Z}(M) \).

Remark 5.3.1.7. In the situation of Definition 5.3.1.6, we will often abuse notation by identifying the center \( \mathfrak{Z}(M) \) with its image in the \( \infty \)-category \( \text{Alg}(\mathcal{C}) \) of associative algebra objects of the monoidal \( \infty \)-category \( \mathcal{C} \).

Our first goal is to show that, as our notation suggests, the theory of centers is closely related to the theory of centralizers. Namely, we have the following:

Proposition 5.3.1.8. Let \( q : \mathcal{C} \to \mathcal{LM}^\otimes \) be a coCartesian fibration of \( \infty \)-operads, and let \( M \in \mathcal{M} = \mathcal{C}_m \). Suppose that there exists a centralizer of the canonical equivalence \( \epsilon : 1 \otimes M \to M \). Then there exists a center of \( M \). Moreover, a lifting \( \overline{M} \in \mathcal{LMod}_A(\mathcal{M}) \) of \( M \) exhibits \( A \) as a center of \( M \) if and only if the diagram

\[
\begin{array}{ccc}
A \otimes M & \xrightarrow{\epsilon} & M \\
\downarrow & & \\
1 \otimes M & \xrightarrow{e} & M \\
\end{array}
\]

exhibits \( A \) as a centralizer of \( e \).

The proof will require a few preliminaries.

Lemma 5.3.1.9. Let \( q : \mathcal{C} \to \mathcal{LM}^\otimes \) be a fibration of \( \infty \)-operads which exhibits the \( \infty \)-category \( \mathcal{M} = \mathcal{C}_m \) as weakly enriched over the planar \( \infty \)-operad \( \mathcal{C}_a^\otimes \). Assume that \( \mathcal{C}^\otimes \) admits a unit object (Definition 3.2.1.1), and let \( \theta : \mathcal{LMod}(\mathcal{M}) \to \mathcal{M} \) be the forgetful functor.
(1) The functor $\theta$ admits a left adjoint $L$.

(2) Let $\text{LMod}'(M) \subseteq \text{LMod}(M)$ be the essential image of $L$. Then $\theta$ induces a trivial Kan fibration $\text{LMod}'(M) \to \mathcal{M}$. In particular, $L$ is fully faithful.

(3) An object $(A, M) \in \text{LMod}(M)$ belongs to $\text{LMod}'(M)$ if and only if $A$ is a trivial algebra object of $\mathcal{C}_n$ (see §ref{refuniv}).

**Proof.** Let us identify the $\infty$-operad $\mathcal{T}riv$ with the full subcategory of $\mathcal{L}M$ spanned by those objects having the form $(\langle n \rangle, \langle n \rangle^\triangleright)$. The functor $\theta$ factors as a composition

$$\text{LMod}(M) \xrightarrow{\theta'} \text{Alg}_{\mathcal{T}riv/ \mathcal{L}M}(\mathcal{C}) \xrightarrow{\theta''} \mathcal{M},$$

where $\theta''$ is a trivial Kan fibration (Example 2.1.3.5). To prove (1), it will suffice to show that $\theta'$ admits a left adjoint. We claim that this left adjoint exists, and is given by operadic $q$-left Kan extension along the inclusion $\mathcal{T}riv^\circ \subseteq \mathcal{L}M^\circ$. According to Proposition 3.1.3.3, it suffices to verify that for each $\overline{M} \in \text{Alg}_{\mathcal{T}riv/ \mathcal{L}M}(\mathcal{C})$ and every object of the form $X \in \mathcal{L}M$, the map $\mathcal{T}riv^\circ \times_{\mathcal{L}M^\circ}(\mathcal{L}M^\circ)^{\text{act}}/X \to \mathcal{C}^\circ$ can be extended to an operadic $q$-colimit diagram (lying over the natural map $(\mathcal{T}riv^\circ \times_{\mathcal{L}M^\circ}(\mathcal{L}M^\circ)^{\text{act}})/X \to \mathcal{L}M^\circ$). If $X = m$, then $X \in \mathcal{T}riv^\circ$ and the result is obvious. If $X = a$, then the desired result follows from our assumption that $\mathcal{C}^\circ$ admits an $\mathbb{A}$-unit. This proves (1). Moreover, we see that if $\overline{A} = (A, M) \in \text{LMod}(M)$, then a map $f : \overline{M} \to \overline{A}|\mathcal{T}riv^\circ$ exhibits $\overline{A}$ as a free $\mathcal{L}M$-algebra generated by $\overline{M}$ if and only if $\overline{A}|\text{Ass}^\circ$ is a trivial algebra and $f$ is an equivalence. It follows that the unit map $\text{id} \to \theta \circ L$ is an equivalence, so that $L$ is a fully faithful embedding whose essential image $\text{LMod}'(M)$ is as described in assertion (3). To complete the proof, we observe that $\theta|\text{LMod}'(M)$ is an equivalence of $\infty$-categories and also a categorical fibration, and therefore a trivial Kan fibration.

**Lemma 5.3.1.10.** Let $q : \mathcal{C}^\circ \to \mathcal{L}M^\circ$ be a coCartesian fibration of $\infty$-operads which exhibits the $\infty$-category $\mathcal{M} = \mathcal{C}_m$ as left-tensored over the monoidal $\infty$-category $\mathcal{C}^\circ$. Let $A \in \text{Alg}(\mathcal{C}_n)$ be a trivial algebra object, and let $\overline{M} \in \text{LMod}_{\mathcal{A}}(\mathcal{M})$. Let $\mathcal{C}^\circ = \mathcal{C}^\circ_{\mathcal{L}M/\mathcal{M}}$ be defined as in Notation 2.2.2.3, let $\mathcal{M}' = \mathcal{C}_m \simeq \mathcal{M}/_{M}$, and let $M' = \text{id}_M \in \mathcal{M}'$. Then the forgetful functor

$$\theta : \text{LMod}(\mathcal{M}') \times_{\mathcal{M}'} \{M'\} \to \text{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{M\}$$

is a trivial Kan fibration. In particular, $M$ has a center in $\mathcal{C}^\circ$ if and only if $M'$ has a center in $\mathcal{C}^\circ$.

**Proof.** Note that $\overline{M} : \mathcal{L}M^\circ \to \mathcal{C}^\circ$ is a coCartesian section of $q$, so that $\mathcal{C}^\circ \to \mathcal{L}M^\circ$ is a coCartesian fibration of $\infty$-operads (Theorem 2.2.2.4). Since $\theta$ is evidently a categorical fibration, it will suffice to show that $\theta$ is a trivial Kan fibration. To this end, we let $A$ denote the full subcategory of $\text{Fun}(\Delta^1, \text{LMod}(M))$ spanned by those morphisms $(N, B) \to (N', B')$ which exhibit $(N, B)$ as an $\text{LMod}'(M)$-colocalization of $(N', B')$, where $\text{LMod}'(M)$ is the full subcategory of $\text{LMod}(M)$ described in Lemma 5.3.1.9 (in other words, a morphism $(N, B) \to (N', B')$ belongs to $A$ if and only if $B$ is a trivial algebra and the map $N \to N'$ is an equivalence in $\mathcal{M}$). Evaluation at $\{1\} \subseteq \Delta^1$ and $m \in \mathcal{L}M$ induces a functor $e : A \to \mathcal{M}$. The map $\theta$ factors as a composition

$$\text{LMod}(\mathcal{M}') \times_{\mathcal{M}'} \{M'\} \xrightarrow{\theta'} A \times_{M} \{M\} \xrightarrow{\theta''} \text{LMod}(\mathcal{M}) \times_{\mathcal{M}} \{M\},$$

where $\theta''$ is a pullback of the trivial Kan fibration $A \to \text{LMod}(M)$ given by evaluation at $\{1\}$. We conclude by observing that $\theta'$ is also an equivalence of $\infty$-categories.

**Lemma 5.3.1.11.** Let $\mathcal{M}$ be an $\infty$-category left-tensored over a monoidal $\infty$-category $\mathcal{C}^\circ$, let $M \in \mathcal{M}$ be an object, and suppose that there exists a morphism object $\text{Mor}_{\mathcal{M}}(M, M)$. Then there exists a center $\mathfrak{z}(M)$. Moreover, an object $\overline{M} \in \text{LMod}_{\mathcal{A}}(\mathcal{M})$ lifting $M$ exhibits $A$ as a center of $M$ if and only if the canonical map $A \otimes M \to M$ exhibits $A$ as a morphism object $\text{Mor}_{\mathcal{M}}(M, M)$.

**Proof.** Combine Corollary 4.7.2.42, Corollary 3.2.2.5, and Proposition 4.2.2.11.
5.3. CENTERS AND CENTRALIZERS

Proof of Proposition 5.3.1.8. Combine Lemma 5.3.1.10, Lemma 5.3.1.11, and Remark 5.3.1.4.

We are primarily interested in studying centralizers in the setting of $\mathcal{O}^\otimes$-algebra objects of a symmetric monoidal $\infty$-category $\mathcal{C}^\otimes$. To emphasize the role of $\mathcal{O}^\otimes$, it is convenient to introduce a special notation for this situation:

**Definition 5.3.1.12.** Let $\mathcal{O}^\otimes$ and $\mathcal{D}^\otimes$ be $\infty$-operads, and let $p : \mathcal{O}^\otimes \times \mathcal{LM}^\otimes \to \mathcal{D}^\otimes$ be a bifunctor of $\infty$-operads. Suppose that $q : \mathcal{E}^\otimes \to \mathcal{D}^\otimes$ is a coCartesian fibration of $\infty$-operads. Then we have an induced coCartesian fibration of $\infty$-operads $q' : \text{Alg}_{\mathcal{O}/\mathcal{D}}(\mathcal{E})^\otimes \to \mathcal{LM}^\otimes$. If $f : A \to B$ is a morphism in $\text{Alg}_{\mathcal{O}}(\mathcal{E})_m$, then we let $\mathcal{Z}_O(f)$ denote the centralizer of $f$ (as a morphism in $\text{Alg}_{\mathcal{O}}(\mathcal{E})^\otimes$), provided that this centralizer exists. If $A \in \text{Alg}_{\mathcal{O}}(\mathcal{E})_m$, we let $\mathcal{Z}_O(A)$ denote the center of $A$, provided that such a center exists.

**Remark 5.3.1.13.** The primary case of interest to us is that in which $\mathcal{D}^\otimes = N(\text{Fin}_*)$, so that $\mathcal{E}^\otimes$ can be regarded as a symmetric monoidal $\infty$-category and the map $p : \mathcal{O}^\otimes \times \mathcal{LM}^\otimes \to \mathcal{D}^\otimes$ is uniquely determined. In this case, we will denote $\text{Alg}_{\mathcal{O}/\mathcal{D}}(\mathcal{E})^\otimes_m \simeq \text{Alg}_{\mathcal{O}/\mathcal{D}}(\mathcal{E})_m$ simply by $\text{Alg}_{\mathcal{O}}(\mathcal{E})$. If $A \in \text{Alg}_{\mathcal{O}}(\mathcal{E})$, we can identify the center $\mathcal{Z}_O(A)$ (if it exists) with an associative algebra object of the symmetric monoidal $\infty$-category $\text{Alg}_{\mathcal{O}}(\mathcal{E})$. If $\mathcal{O}^\otimes$ is a little cubes operad, then Theorem 5.1.2.2 and Example 5.1.0.7 provide equivalences of $\infty$-categories

$$\text{Alg}_{\mathcal{E}_{k+1}}(\mathcal{E}) \to \text{Alg}_{\mathcal{E}_{k}}(\text{Alg}_{\mathcal{E}_{k}}(\mathcal{E})) \leftarrow \text{Alg}(\text{Alg}_{\mathcal{E}_{k}}(\mathcal{E})),$$

so we can identify $\mathcal{Z}_{\mathcal{E}_{k}}(A)$ with an $\mathcal{E}_{k+1}$-algebra object of $\mathcal{E}$.

In the situation of Definition 5.3.1.12, it is generally not possible to prove the existence of centralizers by direct application of Lemma 5.3.1.11: the tensor product of $\mathcal{O}$-algebra objects usually does not commute with colimits in either variable, so there generally does not exist a morphism object $\text{Mor}_{\text{Alg}_{\mathcal{O}}(\mathcal{E})_m}(A,B)$ for a pair of algebras $A,B \in \text{Alg}_{\mathcal{O}}(\mathcal{E})_m$. Nevertheless, if $\mathcal{O}$ is coherent, then we will show that the centralizer $\mathcal{Z}_O(f)$ of a morphism $f : A \to B$ exists under very general conditions:

**Theorem 5.3.1.14.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, let $p : \mathcal{O}^\otimes \times \mathcal{LM}^\otimes \to \mathcal{D}^\otimes$ be a bifunctor of $\infty$-operads, and let $q : \mathcal{E}^\otimes \to \mathcal{D}^\otimes$ exhibit $\mathcal{E}^\otimes$ as a presentable $\mathcal{D}$-monoidal $\infty$-category. Then, for every morphism $f : A \to B$ in $\text{Alg}_{\mathcal{O}}(\mathcal{E})_m$, there exists a centralizer $\mathcal{Z}_O(f)$.

**Corollary 5.3.1.15.** Let $k \geq 0$, and let $\mathcal{E}^\otimes$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{E}$ is presentable and that the tensor product $\otimes : \mathcal{E} \times \mathcal{E} \to \mathcal{E}$ preserves small colimits separately in each variable. Then:

1. For every morphism $f : A \to B$ in $\text{Alg}_{\mathcal{E}_{k}}(\mathcal{E})$, there exists a centralizer $\mathcal{Z}_{\mathcal{E}_{k}}(f) \in \text{Alg}_{\mathcal{E}_{k}}(\mathcal{E})$.
2. For every object $A \in \text{Alg}_{\mathcal{E}_{k}}(\mathcal{E})$, there exists a center $\mathcal{Z}_{\mathcal{E}_{k}}(A) \in \text{Alg}(\text{Alg}_{\mathcal{E}_{k}}(\mathcal{E})) \simeq \text{Alg}_{\mathcal{E}_{k+1}}(\mathcal{E})$.

**Proof.** Combine Theorems 5.3.1.14 and 5.1.1.1.

**Corollary 5.3.1.16.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, and let $q : \mathcal{E}^\otimes \to N(\text{Fin}_*)$ exhibit $\mathcal{E}^\otimes$ as a presentable symmetric monoidal $\infty$-category. Let $K$ be a small simplicial set which is weakly contractible. Then the tensor product functor $\otimes : \text{Alg}_{\mathcal{O}}(\mathcal{E}) \times \text{Alg}_{\mathcal{O}}(\mathcal{E}) \to \text{Alg}_{\mathcal{O}}(\mathcal{E})$ preserves $K$-indexed colimits in each variable.

**Proof.** Let $q : K \to \text{Alg}_{\mathcal{O}}(\mathcal{E})$ be a diagram with limit $A$, and suppose we are given algebra objects $B, C \in \text{Alg}_{\mathcal{O}}(\mathcal{E})$. We wish to prove that the map $\theta$ appearing in the diagram

$$
\begin{array}{ccc}
\text{Map}_{\text{Alg}_{\mathcal{O}}(\mathcal{E})}(A \otimes B, C) & \longrightarrow & \lim_{v \in K} \text{Map}_{\text{Alg}_{\mathcal{O}}(\mathcal{E})}(q(v) \otimes B, C) \\
\downarrow \theta & & \\
\text{Map}_{\text{Alg}_{\mathcal{O}}(\mathcal{E})}(B, C) & \longrightarrow & \text{Map}_{\text{Alg}_{\mathcal{O}}(\mathcal{E})}(B, C)
\end{array}
$$

exists.
is a homotopy equivalence. For this, it suffices to show that $\theta$ induces a homotopy equivalence after passing to the homotopy fiber over any point $f \in \text{Map}_{\mathcal{E}_k}(C)$. This is clear, since the map of homotopy fibers can be identified with the natural map

$$\text{Map}_{\mathcal{E}_k}(C)(A, 3_\mathcal{C}(f)) \to \lim_{v \in K} \text{Map}_{\mathcal{E}_k}(C)(q(v), 3_\mathcal{C}(f)).$$

\[\square\]

**Corollary 5.3.1.17.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{C}$ is compactly generated, and that the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves compact objects and preserves small colimits in each variable. Let $k \geq 0$. Then:

1. The $\infty$-category $\mathcal{E}_k(\mathcal{C})$ is compactly generated.

2. The tensor product $\otimes : \mathcal{E}_k(\mathcal{C}) \times \mathcal{E}_k(\mathcal{C}) \to \mathcal{E}_k(\mathcal{C})$ preserves compact objects separately in each variable.

**Proof.** Since the forgetful functor $\mathcal{E}_k(\mathcal{C}) \to \mathcal{C}$ preserves filtered colimits, the free algebra functor $\text{Free} : \mathcal{C} \to \mathcal{E}_k(\mathcal{C})$ carries compact objects of $\mathcal{C}$ to compact objects of $\mathcal{E}_k(\mathcal{C})$. Let $X$ denote the smallest full subcategory of $\mathcal{E}_k(\mathcal{C})$ which is closed under finite colimits and contains $\text{Free}(C)$, for each compact object. Then $X$ consists of compact objects of $\mathcal{E}_k(\mathcal{C})$, so the inclusion $X \to \mathcal{E}_k(\mathcal{C})$ extends to a fully faithful embedding $F : \text{Ind}(X) \to \mathcal{E}_k(\mathcal{C})$ which preserves filtered colimits. Using Proposition T.5.5.1.9, we see that $F$ preserves small colimits. Since $\mathcal{E}_k(\mathcal{C})$ is presentable (Corollary 3.2.3.5), the functor $F$ admits a right adjoint $G$ (Corollary T.5.5.2.9). To prove that $F$ is an equivalence of $\infty$-categories, it will suffice to show that $G$ is conservative. Let $\alpha : A \to B$ be a morphism of $\mathcal{E}_k$-algebra objects of $\mathcal{C}$ such that $G(\alpha)$ is an equivalence. Then $\alpha$ induces a homotopy equivalence $\text{Map}_C(C, A) \to \text{Map}_C(C, B)$ for every compact object $C \in \mathcal{C}$. Since $\mathcal{C}$ is compactly generated, it follows that $\alpha$ is an equivalence. This completes the proof that $\mathcal{C}$ is compactly generated. Moreover, it shows that every compact object of $\mathcal{C}$ is a retract of an object of $X$.

Let $A, B \in \mathcal{E}_k(\mathcal{C})$ be compact; we wish to prove that $A \otimes B$ is a compact object of $\mathcal{E}_k(\mathcal{C})$. Let us first regard $A$ as fixed, and let $\mathfrak{y} \subseteq \mathcal{E}_k(\mathcal{C})$ denote the full subcategory spanned by those objects $B$ for which $A \otimes B$ is compact in $\mathcal{E}_k(\mathcal{C})$. We wish to show that $\mathfrak{y}$ contains all compact objects of $\mathcal{E}_k(\mathcal{C})$. Since $\mathfrak{y}$ is closed under retractors, it will suffice to show that $\mathfrak{y} \subseteq \mathfrak{y}$. Note that $\mathfrak{y}$ contains the initial object $\mathcal{E}_k(\mathcal{C})$ (since $A$ is compact), and is closed under pushouts by Corollary 5.3.1.16. It follows that $\mathfrak{y}$ is closed under finite colimits (see Corollary T.4.4.2.4). To complete the proof that $X \subseteq \mathfrak{y}$, it will suffice to show that $\mathfrak{y}$ contains $\text{Free}(C)$, for every compact object $C \in \mathcal{C}$. We are therefore reduced to proving that $A \otimes \text{Free}(C)$ is compact, whenever $A$ is a compact object of $\mathcal{E}_k(\mathcal{C})$ and $C \in \mathcal{C}$ is compact. Fixing $C$ and allowing $A$ to vary, the same argument allows us to reduce to the case where $A = \text{Free}(C')$ for some compact object $C' \in \mathcal{C}$. The desired result is now an immediate consequence of the presentation of $\text{Free}(C') \otimes \text{Free}(C)$ supplied by Theorem 5.3.3.3.

\[\square\]

**Example 5.3.1.18 (The Drinfeld Center).** Let $\mathcal{C}$ be an $\mathcal{E}_k$-monoidal $\infty$-category. Using Example 2.4.2.4 and Proposition 2.4.2.5, we can view $\mathcal{C}$ as an $\mathcal{E}_k$-algebra object of the $\infty$-category $\text{Cat}_\infty$ (which we regard as endowed with the Cartesian symmetric monoidal structure). Corollary 5.3.1.15 guarantees the existence of a center $3_{\mathcal{E}_k}(\mathcal{C})$, which we can view as an $\mathcal{E}_{k+1}$-monoidal $\infty$-category. In the special case where $k = 1$ and $\mathcal{C}$ is (the nerve of) an ordinary monoidal category, the center $3_{\mathcal{E}_1}(\mathcal{C})$ is also equivalent to the nerve of an ordinary category $\mathcal{Z}$. Example 5.1.2.4 guarantees that $\mathcal{Z}$ admits the structure of a braided monoidal category. This braided monoidal category $\mathcal{Z}$ is called the Drinfeld center of the monoidal category underlying $\mathcal{C}$ (see, for example, [81]). Consequently, we can view the construction $\mathcal{C} \mapsto 3_{\mathcal{E}_k}(\mathcal{C})$ as a higher-categorical generalization of the theory of the Drinfeld center.

Our goal for the remainder of this section is to provide a proof of Theorem 5.3.1.14. The idea is to change $\infty$-categories to maneuver into a situation where Lemma 5.3.1.11 can be applied. To carry out this strategy, we will need to introduce a bit of notation.

Definition 5.3.1.19. Let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad and \( S \) an \( \infty \)-category. A **coCartesian \( S \)-family of \( \mathcal{O} \)-operads** is a map \( q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes \times S \) with the following properties:

(i) The map \( q \) is a categorical fibration.

(ii) The underlying map \( \mathcal{E}^\otimes \to N(F_{\text{fin}}) \times S \) exhibits \( \mathcal{E}^\otimes \) as an \( S \)-family of \( \infty \)-operads, in the sense of Definition 2.3.2.10.

(iii) For every object \( C \in \mathcal{E}^\otimes \) with \( q(C) = (X, s) \in \mathcal{O}^\otimes \times S \) and every morphism \( f : s \to s' \) in \( S \), there exists a \( q \)-coCartesian morphism \( C \to C' \) in \( \mathcal{E}^\otimes \) lifting the morphism \((id_X, f)\).

Remark 5.3.1.20. Let \( q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes \times S \) be a coCartesian \( S \)-family of \( \mathcal{O} \)-operads. Condition (iii) of Definition 5.3.1.19 guarantees that the underlying map \( \mathcal{E}^\otimes \to S \) is a coCartesian fibration, classified by some map \( \chi : S \to \mathcal{C}_{\text{at}}^\infty \). The map \( q \) itself determines a natural transformation from \( \chi \) to the constant functor \( \chi_0 \) taking the value \( \mathcal{O}^\otimes \), so that \( \chi \) determines a functor \( \overline{\chi} : S \to \mathcal{C}_{\text{at}}^\infty \). This construction determines a bijective correspondence between equivalences classes of \( S \)-families of \( \mathcal{O} \)-operads and equivalence classes of functors from \( S \) to the \( \infty \)-category \( (\mathcal{O}^\infty)^S/(\mathcal{O})^\otimes \), where \( \mathcal{O}^\infty \) is the \( \infty \)-category of \( \mathcal{O} \)-operads (see Definition 2.1.4.1).

Definition 5.3.1.21. Let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad, \( S \) an \( \infty \)-category, and \( q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes \times S \) be a coCartesian \( S \)-family of \( \mathcal{O} \)-operads. We define a simplicial set \( \text{Alg}_{\text{fin}}^{\mathcal{O}}(\mathcal{E}) \) equipped with a map \( \text{Alg}_{\text{fin}}^{\mathcal{O}}(\mathcal{E}) \to S \) so that the following universal property is satisfied: for every map of simplicial sets \( T \to S \), there is a canonical bijection of \( \text{Fun}_S(T, \text{Alg}_{\text{fin}}^{\mathcal{O}}(\mathcal{E})) \) with the subset of \( \text{Fun}_{\mathcal{O}^\otimes \times S}(\mathcal{O}^\otimes \times T, \mathcal{E}) \) spanned by those maps with the property that for each vertex \( t \in T \), the induced map \( \mathcal{O}^\otimes \to \mathcal{E}^\otimes_t \) belongs to \( \text{Alg}_{\mathcal{O}}(\mathcal{E})_t \).

Remark 5.3.1.22. If \( q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes \times S \) is as in Definition 5.3.1.21, then the induced map \( q' : \text{Alg}_{\mathcal{O}}^{\mathcal{O}}(\mathcal{E}) \to S \) is a coCartesian fibration. We will refer to a section \( A : S \to \text{Alg}_{\mathcal{O}}^{\mathcal{O}}(\mathcal{E}) \) of \( q' \) as an **\( S \)-family of \( \mathcal{O} \)-algebra objects of \( \mathcal{E} \)**. We will say that an \( S \)-family of \( \mathcal{O} \)-algebra objects of \( \mathcal{E} \) is **coCartesian** if \( A \) carries each morphism in \( S \) to a \( q' \)-coCartesian morphism in \( \text{Alg}_{\mathcal{O}}^{\mathcal{O}}(\mathcal{E}) \).

Definition 5.3.1.23. Let \( \mathcal{O}^\otimes \) be a coherent \( \infty \)-operad, let \( q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes \times S \) be a coCartesian \( S \)-family of \( \mathcal{O} \)-operads, and let \( \mathcal{E}^\otimes_0 \) denote the product \( \mathcal{O}^\otimes \times S \). If \( A \) is an \( S \)-family of algebra objects of \( \mathcal{E} \), we let \( \text{Mod}^\mathcal{O}_A(\mathcal{E}) \) denote the fiber product

\[
\text{Mod}^\mathcal{O}_A(\mathcal{E})^\otimes \times_{p\text{Alg}_{\mathcal{O}}(\mathcal{E})} S,
\]

where \( \text{Mod}^\mathcal{O}(\mathcal{E}) \) and \( p\text{Alg}_{\mathcal{O}}(\mathcal{E}) \) are defined as in §3.3.3 and the map \( S \to p\text{Alg}_{\mathcal{O}}(\mathcal{E}) \) is determined by \( A \). We let \( \text{Mod}^\mathcal{O}_{A, S}(\mathcal{E}) \) denote the fiber product \( \text{Mod}^\mathcal{O}_A(\mathcal{E}) \times_{\text{Mod}^\mathcal{O}_{A, S}(\mathcal{E})} \mathcal{E}_0 \).

Remark 5.3.1.24. Let \( q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes \times S \) be as in Definition 5.3.1.23 and \( A \) is an \( S \)-family of \( \infty \)-operads. Then the \( \infty \)-category \( \text{Mod}^\mathcal{O}_{A, S}(\mathcal{E})^\otimes \) is equipped with an evident forgetful functor \( \text{Mod}^\mathcal{O}_{A, S}(\mathcal{E})^\otimes \to \mathcal{O}^\otimes \times S \). For every object \( s \in S \), the fiber \( \text{Mod}^\mathcal{O}_{A, S}(\mathcal{E})^\otimes_s = \text{Mod}^\mathcal{O}_A(\mathcal{E})^\otimes \times_S \{s\} \) is canonically isomorphic to the \( \infty \)-operad \( \text{Mod}^\mathcal{O}_{A, s}(\mathcal{E})^\otimes \) defined in §3.3.3.

We will need the following technical result, whose proof will be given at the end of this section.

**Proposition 5.3.1.25.** Let \( \mathcal{O}^\otimes \) be a coherent \( \infty \)-operad, \( q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes \times S \) a coCartesian \( S \)-family of \( \mathcal{O} \)-operads, and \( A \in \text{Fun}_S(S, \text{Alg}_{\mathcal{O}}^{\mathcal{O}}(\mathcal{E})) \) a coCartesian \( S \)-family of \( \mathcal{O} \)-algebras. Then:

1. The forgetful functor \( q' : \text{Mod}^\mathcal{O}_{A, S}(\mathcal{E})^\otimes \to \mathcal{O}^\otimes \times S \) is a coCartesian \( S \)-family of \( \infty \)-operads.

2. Let \( \overline{T} \) be a morphism in \( \text{Mod}^\mathcal{O}_{A, S}(\mathcal{E})^\otimes \) whose image in \( \mathcal{O}^\otimes \) is degenerate. Then \( \overline{T} \) is \( q' \)-coCartesian if and only if its image in \( \mathcal{E}^\otimes \) is \( q \)-coCartesian.
Remark 5.3.1.26. In the situation of Proposition 5.3.1.25, suppose that $\mathcal{O}^\otimes$ is the 0-cubes operad $\mathbb{E}_0$. Let $\mathcal{C}$ denote the fiber product $\mathcal{C}^\otimes \times_{\mathcal{O}^\otimes} \mathcal{O}$. Then the forgetful functor $\theta : \text{Mod}_M^{O,S}(\mathcal{C}) \to \mathcal{C}$ is a trivial Kan fibration. To prove this, it suffices to show that $\mathcal{C}$ is a categorical equivalence (since it is evidently a categorical fibration). According to Corollary T.2.4.4.4, it suffices to show that $\theta$ induces a categorical equivalence after passing to the fiber over each vertex of $S$, which follows from Proposition 3.3.3.19.

Suppose now that $q : \mathcal{C} \to \mathcal{O}^\otimes \times_S$ is a coCartesian $S$-family of $\mathcal{O}$-operads and that $A$ is a coCartesian $S$-family of $\mathcal{O}$-algebra objects of $\mathcal{C}$. Then $A$ determines an $S$-family of $\mathcal{O}$-algebra objects of $\text{Mod}_M^{O,S}(\mathcal{C})$, which we will denote also by $A$. Note that, for each $s \in S$, $A_s \in \text{Alg}_{/\mathcal{O}}(\text{Mod}_M^{O,S}(\mathcal{C}))$ is a trivial algebra and therefore initial in $\text{Alg}_{/\mathcal{O}}(\text{Mod}_M^{O,S}(\mathcal{C}))$ (Proposition 3.2.1.8). Let $\text{Alg}_{/\mathcal{O}}^{S}(\mathcal{C})$ be defined as in §T.4.2.2 and let $\text{Alg}_{/\mathcal{O}}^{S}(\mathcal{C})^{A_s}$ be defined similarly. We have a commutative diagram

$$
\begin{array}{ccc}
\text{Alg}_{/\mathcal{O}}^{S}(\text{Mod}_M^{O,S}(\mathcal{C}))^{A_s} & \xrightarrow{\theta} & \text{Alg}_{/\mathcal{O}}^{S}(\mathcal{C})^{A_s} \\
\downarrow & & \downarrow \\
S
\end{array}
$$

The vertical maps are coCartesian fibrations and $\theta$ preserves coCartesian morphisms. Using Corollary 3.4.1.7, we deduce that $\theta$ induces a categorical equivalence after passing to the fiber over each object of $S$. Applying Corollary T.2.4.4.4, we deduce the following:

**Proposition 5.3.1.27.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, $q : \mathcal{C} \to \mathcal{O}^\otimes \times_S$ a coCartesian $S$-family of $\mathcal{O}$-operads, and $A$ a coCartesian $S$-family of $\mathcal{O}$-algebra objects of $\mathcal{C}$. Then the forgetful functor

$$
\theta : \text{Alg}_{/\mathcal{O}}^{S}(\text{Mod}_M^{O,S}(\mathcal{C}))^{A_s} \to \text{Alg}_{/\mathcal{O}}^{S}(\mathcal{C})^{A_s}
$$

is an equivalence of $\infty$-categories.

Proposition 5.3.1.27 provides a mechanism for reducing questions about centralizers of arbitrary algebra morphisms $f : A \to B$ to the special case where $A$ is a trivial algebra.

**Remark 5.3.1.28.** Let $\mathcal{C}^\otimes \to \mathcal{L}M^\otimes$ be a coCartesian fibration of $\infty$-operads which exhibits an $\infty$-category $\mathcal{M} = \mathcal{E}_M$ as left-tensored over the monoidal $\infty$-category $\mathcal{E}_a$. Let $\mathbf{1}$ denote the unit object of $\mathcal{E}_a$, let $f : M_0 \to M$ be a morphism in $\mathcal{M}$, and consider the fiber product $\mathcal{X} = \mathcal{E}_a \times_{\mathcal{M}} M_0/M$, where the map $\mathcal{E}_a \to \mathcal{M}$ is given by tensor product with $M_0$. We will identify the tensor product $\mathbf{1} \otimes M_0$ with $M_0$, so that the pair $(1, f : M_0 \to M)$ can be identified with an object $X \in \mathcal{X}$. The undercategory $\mathcal{X}_{/X}$ can be identified with the fiber product $(\mathcal{E}_a)_1 \times_{\mathcal{M}(M_0)} \mathcal{M}(M_0/M)$. Assume that the $\infty$-category $\mathcal{X}$ has a final object (in other words, there exists a morphism object $\text{Mor}_{\mathcal{M}}(M_0, M)$ in $\mathcal{E}_a$). Using Proposition T.1.2.13.8, we deduce that the forgetful functor $\mathcal{X}_{/X} \to \mathcal{X}$ induces an equivalence between the full subcategories spanned by the final objects of $\mathcal{X}_{/X}$ and $\mathcal{X}$. In other words:

(i) A map $\epsilon : \mathbf{1} \to Z$ in $\mathcal{E}_a$ together with a commutative diagram

$$
\begin{array}{ccc}
Z \otimes M_0 & \xrightarrow{g} & M \\
\downarrow f & & \downarrow g \\
M_0 & \xrightarrow{\epsilon \otimes \text{id}_{M_0}} & Z \otimes M_0
\end{array}
$$

in $\mathcal{M}$ is a centralizer of $f$ if and only if the underlying morphism $g$ exhibits $Z$ as a morphism object $\text{Mor}_{\mathcal{M}}(M_0, M)$. 

(ii) For any object \( Z \in \mathcal{A}_a \) and any morphism \( Z \otimes M_0 \to M \) which exhibits \( Z \) as a morphism object \( \text{Mor}_\mathcal{M}(M_0, M) \), there exists a map \( 1 \to Z \) and a commutative diagram

\[
\begin{array}{ccc}
Z \otimes M_0 & \xrightarrow{g} & M \\
\downarrow{f} & & \downarrow{\text{id}_M} \\
M_0 & \xrightarrow{\epsilon \otimes \text{id}_{M_0}} & \mathcal{A}
\end{array}
\]

satisfying the conditions of (i).

**Proposition 5.3.1.29.** Let \( \mathcal{C} \to \mathcal{O} \otimes \mathcal{L} \mathcal{M} \) be a coCartesian \( \mathcal{L} \mathcal{M} \)-family of \( \mathcal{O} \)-operads, and assume that the induced map \( \text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C}) \to \mathcal{L} \mathcal{M} \) is a coCartesian fibration of \( \mathcal{O} \)-operads (this is automatic if, for example, the map \( \mathcal{C} \to \mathcal{L} \mathcal{M} \) is a coCartesian fibration of \( \mathcal{O} \)-operads). For every object \( X \in \mathcal{O} \), we let \( \mathcal{C}_{X,a} \) denote the fiber of \( q \) over the vertex \((X,a)\), and define \( \mathcal{C}_{X,m} \) similarly. Let \( f : A_0 \to A \) be a morphism in \( \text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C}) \).

Assume that:

1. The \( \mathcal{O} \)-operad \( \mathcal{O} \) is unital.
2. The algebra object \( A_0 \) is trivial (see §3.2.1).

(iii) For every object \( X \in \mathcal{O} \), there exists a morphism object \( \text{Mor}_{\mathcal{C}_{X,m}}(A_0(X), A(X)) \in \mathcal{C}_{X,a} \).

Then:

- (1) There exists a centralizer \( 3_f(\mathcal{C}) \text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C})_a \).
- (2) Let \( Z \in \text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C})_a \) be an algebra object. Then a commutative diagram

\[
\begin{array}{ccc}
Z \otimes A_0 & \xrightarrow{g} & A \\
\downarrow{f} & & \downarrow{\text{id}_A} \\
A_0 & \xrightarrow{\epsilon \otimes \text{id}_{A_0}} & \mathcal{A}
\end{array}
\]

exhibits \( Z \) as a centralizer of \( f \) if and only if, for every object \( X \in \mathcal{O} \), the induced map \( g_X : 3(X) \otimes A_0(X) \to A(X) \) exhibits \( 3(X) \) as a morphism object \( \text{Mor}_{\mathcal{C}_{X,m}}(A_0(X), A(X)) \).

**Proof.** Let \( 1 \in \text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C})_a \) be a trivial algebra; we will abuse notation by identifying the tensor product \( 1 \otimes A_0 \) with \( A_0 \). To prove (1), we must show that the \( \infty \)-category

\[A = (\text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C}))_1/ \times (\text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C})_m)_0/ (\text{Alg}_{\mathcal{C}}^{\mathcal{L} \mathcal{M}}(\mathcal{C})_m)_0//A_0/\]

has a final object. Let \( \mathcal{C}^\otimes_a \) denote the fiber product \( \mathcal{C}^\otimes \times \mathcal{L} \mathcal{M}^\otimes \{a\} \), define \( \mathcal{C}^\otimes_m \) similarly, and set

\[\mathcal{E}^\otimes = (\mathcal{C}^\otimes)_1/ \times (\mathcal{C}^\otimes_m)_0//A_0/\]

(see §2.2.2 for an explanation of this notation). Using Theorem 2.2.2.4 (and assumption (ii)), we deduce that the evident forgetful functor \( \mathcal{E}^\otimes \to \mathcal{O}^\otimes \) is a coCartesian fibration of \( \mathcal{O} \)-operads; moreover, we have a canonical isomorphism \( A \simeq \text{Alg}_{\mathcal{O}}(\mathcal{E}) \). For each object \( X \in \mathcal{O} \), the \( \infty \)-category \( \mathcal{E}_X = \mathcal{E}^\otimes \times \mathcal{O}^\otimes \{X\} \) is equivalent to the fiber product

\[(\mathcal{C}^\otimes_{X,a})_1(X)/ \times (\mathcal{C}^\otimes_{X,m})_{A_0(X)}/ (\mathcal{C}^\otimes_{X,m})_{A_0(X)}/A(X),\]

which has a final object by virtue of assumption (iii) and Remark 5.3.1.28. It follows that \( A \) has a final object; moreover, an object \( A \in A \) \( \text{Alg}_{\mathcal{O}}(\mathcal{E}) \) is final if and only if each \( A(X) \) is a final object of \( \mathcal{E}_X \). This proves (1), and reduces assertion (2) to the contents of Remark 5.3.1.28. □
We now apply Proposition 5.3.1.29 to the study of centralizers in general. Fix a coherent $\infty$-operad $\mathcal{O}^\otimes$, a bifunctor of $\infty$-operads $\mathcal{O}^\otimes \times \mathcal{LM}^\otimes \to \mathcal{D}^\otimes$, and a coCartesian fibration of $\infty$-operads $q : \mathcal{C}^\otimes \to \mathcal{D}^\otimes$. Let $A \in \Alg\mathcal{D}_/\mathcal{D}(\mathcal{E})_m$, and let $\mathcal{A} \in \text{LMod}(\Alg\mathcal{D}_/\mathcal{D}(\mathcal{E}))$ be such that $\mathcal{A}_m = A$ and $\mathcal{A}_a$ is a trivial algebra. We can regard $\mathcal{A}$ as a coCartesian $\mathcal{LM}^\otimes$-family of $\mathcal{O}$-algebra objects of $\mathcal{E}^\otimes \times \mathcal{D}^\otimes((\mathcal{O}^\otimes \times \mathcal{LM}^\otimes))$. Let $\mathcal{C}^\otimes = \text{Mod}^{\mathcal{O},\mathcal{LM}^\otimes}_\mathcal{A}(\mathcal{E})$ be the coCartesian $S$-family of $\mathcal{O}$-operads given by Proposition 5.3.1.25. Since $\mathcal{A}_a$ is trivial, the forgetful functor $\mathcal{C}^\otimes \to \mathcal{C}^\otimes_a = \mathcal{C}^\otimes \times_{\mathcal{D}^\otimes}(\mathcal{O}^\otimes \times \{a\})$ is an equivalence of $\mathcal{O}$-operads, and induces an equivalence of $\infty$-categories $\Alg\mathcal{D}_/\mathcal{O}(\mathcal{C})_a \to \Alg\mathcal{D}_/\mathcal{D}(\mathcal{C})_a$. It follows from Proposition 5.3.1.27 that every morphism $f : A \to B$ in $\Alg\mathcal{D}_/\mathcal{D}(\mathcal{C})_m$ is equivalent to $\theta(f')$, where $f' : A \to B'$ is a morphism in $\Alg\mathcal{O}/\mathcal{O}(\mathcal{C})_m$; here we abuse notation by identifying $A$ with the associated trivial $\mathcal{O}$-algebra object of $\mathcal{C}^\otimes_a$. It follows from Proposition 5.3.1.27 that the forgetful functor $\theta$ induces an identification between centralizers of $f$ in $\Alg\mathcal{O}/\mathcal{D}(\mathcal{E})_a$ and centralizers of $f'$ in $\Alg\mathcal{O}/\mathcal{O}(\mathcal{E})_a$. Combining this observation with Proposition 5.3.1.29, we obtain the following result:

**Theorem 5.3.1.30.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, $\mathcal{O}^\otimes \times \mathcal{LM}^\otimes \to \mathcal{D}^\otimes$ a bifunctor of $\infty$-operads, and $q : \mathcal{C}^\otimes \to \mathcal{D}^\otimes$ a coCartesian fibration of $\infty$-operads. Let $f : A \to B$ be a morphism in $\Alg\mathcal{D}_/\mathcal{D}(\mathcal{E})_m$ and let $\mathcal{C}^\otimes$ and $f' : A \to B'$ be defined as above. Assume that:

(*) For every object $X \in \mathcal{O}$, there exists a morphism object $\text{Mor}_{\mathcal{E}_{X,m}}(A(X), B'(X)) \in \mathcal{C}_{X,a}$.

Then:

1. There exists a centralizer $\mathfrak{Z}(f) \in \Alg\mathcal{D}_/\mathcal{D}(\mathcal{E})_a$.
2. Let $Z$ be an arbitrary object of $\Alg\mathcal{D}_/\mathcal{D}(\mathcal{E})_a$, and let $\sigma$:

$$
\begin{array}{ccc}
Z \otimes A & \xrightarrow{g} & B \\
\downarrow f & & \downarrow \\
A & \xrightarrow{\sigma} & B
\end{array}
$$

be a commutative diagram in $\Alg\mathcal{D}_/\mathcal{D}(\mathcal{E})_m$. Let $Z'$ be a preimage of $Z$ in $\Alg\mathcal{O}(\mathcal{E})_a$, so that $\sigma$ lifts (up to homotopy) to a commutative diagram

$$
\begin{array}{ccc}
Z' \otimes A & \xrightarrow{f'} & B' \\
\downarrow & & \downarrow \\
A & \xrightarrow{A} & B'
\end{array}
$$

in $\Alg\mathcal{O}(\mathcal{E})_m$. Then $\sigma$ exhibits $Z$ as a centralizer of $f$ if and only if, for every object $X \in \mathcal{O}$, the induced map $Z'(X) \otimes A(X) \to B'(X)$ exhibits $Z'(X)$ as a morphism object $\text{Mor}_{\mathcal{E}_{X,m}}(A(X), B'(X)) \in \mathcal{C}_{X,a}$.

**Corollary 5.3.1.31.** In the situation of Theorem 5.3.1.30, suppose that $\mathcal{O}^\otimes$ is the $0$-cubes $\infty$-operad $\mathcal{E}_0$. Then we can identify centralizers of a morphism $f : A \to B$ in $\Alg\mathcal{D}_/\mathcal{D}(\mathcal{E})_m$ with morphism objects $\text{Mor}_{\mathcal{E}_a}(A, B)$ in $\mathcal{E}_a$.

**Proof.** Combine Theorem 5.3.1.30 with Remark 5.3.1.26.

**Remark 5.3.1.32.** More informally, we can state Theorem 5.3.1.30 as follows: the centralizer of a morphism $f : A \to B$ can be identified with the classifying object for $A$-module maps from $A$ to $B$. In particular, the center $\mathfrak{Z}(A)$ can be identified with the endomorphism algebra of $A$, regarded as a module over itself.

We now return to the proof of our main result.
Proof of Theorem 5.3.1.14. Combine Theorem 5.3.1.30, Proposition 4.2.1.33, and Theorem 3.4.4.2.

We conclude this section with the proof of Proposition 5.3.1.25. First, we need a lemma.

**Lemma 5.3.1.33.** Let \( n \geq 2 \), and let \( \mathcal{C} \to \Delta^n \) be an inner fibration of \( \infty \)-categories. Let \( q : \mathcal{D} \to \mathcal{C} \) be another inner fibration of \( \infty \)-categories. Every lifting problem of the form

\[
\begin{array}{ccc}
\Lambda_0^n \times \Delta^n & \to & \mathcal{D} \\
\downarrow & \searrow & \downarrow g \\
\mathcal{C} & \to & \mathcal{E}
\end{array}
\]

admits a solution, provided that \( g|\Delta^{\{0,1\}} \times \Delta^n \mathcal{C} \) is a \( q \)-left Kan extension of \( g|\{0\} \times \Delta^n \mathcal{C} \).

**Proof.** We first define a map \( r : \Delta^n \times \Delta^1 \to \Delta^n \), which is given on vertices by the formula

\[
r(i,j) = \begin{cases} 
0 & \text{if } (i,j) = (1,0) \\
1 & \text{otherwise},
\end{cases}
\]

and let \( j : \Delta^n \to \Delta^n \times \Delta^1 \) be the map \((\text{id}, j_0)\), where \( j_0 \) carries the first two vertices of \( \Delta^n \) to \( \{0\} \subseteq \Delta^1 \) and the remaining vertices to \( \{1\} \subseteq \Delta^1 \).

Let \( K = (\Lambda_0^n \times \Delta^1) \amalg_{\Lambda_0^n \times \{0\}} (\Delta^n \times \{0\}) \), let \( \mathcal{C}' = (\Delta^n \times \Delta^1) \times \Delta^n \mathcal{C} \), and let \( \mathcal{C}'_0 = K \times \Delta^n \mathcal{C} \). We will show that there exists a solution to the lifting problem

\[
\begin{array}{ccc}
\mathcal{C}'_0 & \to & \mathcal{D} \\
\downarrow & \searrow & \downarrow g \\
\mathcal{C}' & \to & \mathcal{E}
\end{array}
\]

Composing this solution with the map \( \mathcal{C} \to \mathcal{C}' \) induced by \( j \), we will obtain the desired result.

For every simplicial subset \( L \subseteq \Delta^n \), let \( \mathcal{C}'_L \) denote the fiber product

\[(L \times \Delta^1) \amalg_{L \times \{0\}} (\Delta^n \times \{0\}) \times \Delta^n \mathcal{C},\]

and let \( X_L \) denote the full subcategory of \( \text{Fun}_{\mathcal{E}}(\mathcal{C}'_L, \mathcal{D}) \times \text{Fun}_{\mathcal{C}}(\mathcal{E}', \mathcal{D}) \{g'|\mathcal{C}_0\} \) spanned by those functors \( F \) with the following property: for each vertex \( v \in L \), the restriction of \( F \) to \((\{v\} \times \Delta^1) \times \Delta^n \mathcal{C} \) is a \( q \)-left Kan extension of \( F|((\{v\} \times \{0\}) \times \Delta^n \mathcal{C}) \).

To complete the proof, it will suffice to show that the restriction map \( X_{\Delta^n} \to X_{\Lambda_0^n} \) is surjective on vertices. We will prove the following stronger assertion:

\((\ast)\) For every inclusion \( L' \subseteq L \) of simplicial subsets of \( \Delta^n \), the restriction map \( \theta_{L',L} : X_L \to X_{L'} \) is a trivial Kan fibration.

The proof proceeds by induction on the number of nondegenerate simplices of \( L \). If \( L' = L \), then \( \theta_{L',L} \) is an isomorphism and there is nothing to prove. Otherwise, choose a nondegenerate simplex \( \sigma \) of \( L \) which does not belong to \( L' \), and let \( L_0 \) be the simplicial subset of \( L \) obtained by removing \( \sigma \). The inductive hypothesis guarantees that the map \( \theta_{L_0,L} \) is a trivial Kan fibration. Consequently, to show that \( \theta_{L',L} \) is a trivial Kan fibration, it will suffice to show that \( \theta_{L_0,L} \) is a trivial Kan fibration. Note that \( \theta_{L_0,L} \) is a pullback of the map \( \theta_{\emptyset,\sigma} \): we may therefore assume without loss of generality that \( L = \sigma \) is a simplex of \( \Delta^n \).

Since the map \( \theta_{L',L} \) is evidently a categorical fibration, it will suffice to show that each \( \theta_{L',L} \) is a categorical equivalence. We may assume by the inductive hypothesis that \( \theta_{\emptyset,L'} \) is a categorical equivalence. By a two-out-of-three argument, we may reduce to the problem of showing that \( \theta_{\emptyset,L'} \circ \theta_{L',L} = \theta_{\emptyset,L} \) is a categorical equivalence. In other words, we may assume that \( L' \) is empty. We are now reduced to the problem of showing that the map \( X_{\sigma} \to X_{\emptyset} \) is a trivial Kan fibration, which follows from Proposition T.4.3.2.15.

\[\square\]
Proof of Proposition 5.3.1.25. It follows from Remark 3.3.3.15 that $q'$ is a categorical fibration and the induced map $\operatorname{Mod}_{A}^{O,S}(\mathcal E) \to N(\mathcal F_{0}) \times S$ exhibits $\operatorname{Mod}_{A}^{O,S}(\mathcal E)$ as an $S$-family of $\infty$-operads (note that the projection $\operatorname{Mod}_{A}^{O,S}(\mathcal E) \to \operatorname{Mod}_{A}^{O}(\mathcal E)$ is an equivalence of $\infty$-categories). To complete the proof of (1), it will suffice to show that $q'$ satisfies condition (iii) of Definition 5.3.1.19. That is, we must show that if $M$ is an object of $\operatorname{Mod}_{A}^{O,S}(\mathcal E)$ having image $(X,s)$ in $\mathcal O \times S$ and $f : s \to s'$ is a morphism in $S$, then $(\prescript{1}{}{q}, f)$ can be lifted to a $q'$-coCartesian morphism $M \to M'$ in $\operatorname{Mod}_{A}^{O,S}(\mathcal E)$. Let $A$ be the full subcategory of $(\mathcal E)^{X}$ spanned by the semi-inert morphisms $X \to Y$ in $\mathcal O$, and let $A_{0}$ be the full subcategory of $A$ spanned by the null morphisms. The object $M \in \operatorname{Mod}_{A}^{O,S}(\mathcal E)$ determines a functor $F : A \to \mathcal E$. Let $F_{0}$ denote the composite map $A \xrightarrow{\xi} \mathcal E \to \mathcal O$. Since $q$ exhibits $\mathcal E$ as a coCartesian $S$-family of $\infty$-operads, there exists a $q$-coCartesian natural transformation $H : A \times \Delta^{1} \to \mathcal E$ from $F$ to another map $F'$, such that $q \circ H$ is the product map $A \times \Delta^{1} \xrightarrow{F_{0} \times f} \mathcal O \times S$. Let $H' : A_{0} \times \Delta^{1} \to \mathcal O$ be the composition $A_{0} \times \Delta^{1} \to \mathcal O \times S \xrightarrow{\Lambda} \mathcal E$. Since $A$ is a coCartesian $S$-family of $O$-algebras, the functors $H|A_{0} \times \Delta^{1}$ and $H'$ are equivalent; we may therefore modify $H$ by a homotopy (fixed on $A \times \{0\}$) and thereby assume that $H|A_{0} \times \Delta^{1} = H'$, so that $H$ determines a morphism $\alpha : M \to M'$ in $\operatorname{Mod}_{A}^{O,S}(\mathcal E)$ lying over $(\prescript{1}{}{q}, f)$. To complete the proof of (1), it will suffice to show that $\alpha$ is $q'$-coCartesian.

Let $\mathcal O = \mathcal O \times S$. We have a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\operatorname{Mod}_{A}^{O}(\mathcal E) & \xrightarrow{q} & \operatorname{Mod}_{A}^{O}(\mathcal E) \\
\downarrow & & \downarrow \quad p' \\
\mathcal O \times S & \to & \mathcal O \times p\operatorname{Alg}_{O}(\mathcal E) \times_{p\operatorname{Alg}_{O}(\mathcal E)} \mathcal E
\end{array}
$$

Since the upper square is a pullback diagram, it will suffice to show that $r(\alpha)$ is $p'$-coCartesian. In view of Proposition T.2.4.1.3, we are reduced to showing that $r(\alpha)$ is $p$-coCartesian and that $(p' \circ r)(\alpha)$ is $p''$-coCartesian.

To prove that $r(\alpha)$ is $p$-coCartesian, we must show that every lifting problem of the form

$$
\begin{array}{ccc}
\Lambda^{n}_{0} & \xrightarrow{g} & \operatorname{Mod}_{A}^{O}(\mathcal E) \\
\downarrow & & \downarrow \quad p \\
\Delta^{n} & \to & \mathcal E
\end{array}
$$

admits a solution, provided that $n \geq 2$ and that $g$ carries the initial edge of $\Lambda^{n}_{0}$ to the morphism determined by $H$. Unwinding the definitions, this amounts to solving a lifting problem of the form

$$
\begin{array}{ccc}
\Lambda^{n}_{0} \times \mathcal O \times \mathcal K_{0} & \xrightarrow{G} & \mathcal E \\
\downarrow & & \downarrow \\
\Delta^{n} \times \mathcal O \times \mathcal K_{0} & \to & \mathcal O \times S.
\end{array}
$$

The existence of a solution to this lifting problem is guaranteed by Lemma 5.3.1.33. The assertion that $(p' \circ r)(\alpha)$ is $p''$-coCartesian can be proven in the same way. This completes the proof of (1).

Let $\overline{f} : M \to M''$ be as in (2), let $f$ be the image of $\overline{f}$ in $S$, and let $\overline{f} : M \to M'$ be the $q'$-coCartesian map constructed above. We have a commutative diagram

$$
\begin{array}{ccc}
\overline{f} & \xrightarrow{g} & M' \\
\downarrow & & \downarrow \quad \overline{f} \\
M & \to & M''.
\end{array}
$$
Let $\theta : \text{Mod}_A^\varnothing(\mathcal{C})^\circ \to \mathcal{C}^\circ$ be the forgetful functor. By construction, $\theta(\mathcal{J})$ is a $q$-coCartesian morphism in $\mathcal{C}^\circ$, so that $\theta(f)$ is $q$-coCartesian if and only if $\theta(g)$ is an equivalence. We note that $\mathcal{J}$ is $q'$-coCartesian if and only if the map $g$ is an equivalence. The “only if” direction of (2) is now obvious, and the converse follows from Remark 5.3.1.24 together with Corollary 3.4.3.4. \[\square\]

### 5.3.2 The Adjoint Representation

Let $A$ be an associative ring, and let $A^\times$ be the collection of units in $A$. Then $A^\times$ forms a group, which acts on $A$ by conjugation. This action is given by a group homomorphism $\phi : A^\times \to \text{Aut}(A)$ whose kernel is the subgroup of $A^\times$ consisting of units which belong to the center: this group can be identified with the group of units of the center $\mathfrak{Z}(A)$. In other words, we have an exact sequence of groups

$$0 \to \mathfrak{Z}(A)^\times \to A^\times \to \text{Aut}(A).$$

Our goal in this section is to prove a result which generalizes this statement in the following ways:

(a) In place of a single associative ring $A$, we will consider instead a map of algebras $f : A \to B$. In this setting, we will replace the automorphism group $\text{Aut}(A)$ by the set $\text{Hom}(A,B)$ of algebra homomorphisms from $A$ to $B$. This set is acted on (via conjugation) by the group $B^\times$ of units in $B$. Moreover, the stabilizer of the element $f \in \text{Hom}(A,B)$ can be identified with the group of units $\mathfrak{Z}(f)^\times$ of the centralizer of the image of $f$. In particular, we have an exact sequence of pointed sets

$$\mathfrak{Z}(f)^\times \hookrightarrow B^\times \to \text{Hom}(A,B).$$

(b) Rather than considering rings (which are associative algebra objects of the category of abelian groups), we will consider algebra objects in an arbitrary symmetric monoidal $\infty$-category $\mathcal{C}$. In this setting, we need to determine appropriate analogues of the sets $3(f)^\times$, $B^\times$, and $\text{Hom}(A,B)$ considered above. In the last case this is straightforward: the analogue of the set $\text{Hom}(A,B)$ of ring homomorphisms from $A$ to $B$ is the *space* $\text{Map}_{\text{Alg}(\mathcal{C})}(A,B)$ of morphisms in the $\infty$-category $\text{Alg}(\mathcal{C})$. Note that the spaces $\text{Map}_{\mathcal{C}}(1,\mathfrak{Z}(f))$ and $\text{Map}_{\mathcal{C}}(1,B)$ are equipped with (coherently) associative multiplications (see Definition 5.3.2.4), so that the sets $\pi_0 \text{Map}_{\mathcal{C}}(1,\mathfrak{Z}(f))$ and $\pi_0 \text{Map}_{\mathcal{C}}(1,B)$ have the structure of associative monoids. We let $\mathfrak{Z}(f)^\times \subseteq \text{Map}_{\mathcal{C}}(1,\mathfrak{Z}(f))$ be the union of those connected components corresponding to invertible elements of $\pi_0 \text{Map}_{\mathcal{C}}(1,\mathfrak{Z}(f))$, and let and $B^\times \subseteq \text{Map}_{\mathcal{C}}(1,B)$ be defined similarly.

The collection of units in an associative ring $R$ is equipped with the structure of group (with respect to multiplication). We will see that there is an analogous structure on the space of units $B^\times$ for an associative algebra object $B$ of an arbitrary symmetric monoidal $\infty$-category $\mathcal{C}$: namely, $B^\times$ is a loop space. That is, there exists a pointed space $X(B)$ and a homotopy equivalence $B^\times \simeq \Omega X(B)$. There is an “action” of the loop space $B^\times$ on the mapping space $\text{Map}_{\text{Alg}(\mathcal{C})}(A,B)$. This action is encoded by a fibration $X(A,B) \to X(B)$, whose homotopy fiber (over the base point of $X(B)$) can be identified with $\text{Map}_{\text{Alg}(\mathcal{C})}(A,B)$. In particular, a morphism of associative algebra objects $f : A \to B$ determines a base point of $X(A,B)$, and we will see that the loop space $\Omega X(A,B)$ can be identified with the space of units $\mathfrak{Z}(f)^\times$. In other words, we have a fiber sequence of spaces

$$\text{Map}_{\text{Alg}(\mathcal{C})}(A,B) \to X(A,B) \to X(B)$$

which, after looping the base and total space, yields a fiber sequence

$$\mathfrak{Z}(f)^\times \to B^\times \to \text{Map}_{\text{Alg}(\mathcal{C})}(A,B)$$

analogous to the exact sequence of sets described in (a).

(c) Instead of considering only associative algebras, we will consider algebras over an arbitrary little cubes operad $\mathcal{E}_k$ (according to Example 5.1.0.7, we can recover the case of associative algebras by setting...
If \( B \) is an \( \mathbb{E}_k \)-algebra object of a symmetric monoidal \( \infty \)-category \( \mathcal{C} \), then we can again define a space of units \( B^\times \subseteq \text{Map}_C(1, B) \). The space \( B^\times \) has the structure of a \( k \)-fold loop space: that is, one can define a pointed space \( X(B) \) and a homotopy equivalence \( B^\times \simeq \Omega^k X(B) \). If \( A \) is another \( \mathbb{E}_k \)-algebra object of \( \mathcal{C} \), then there exists a fibration \( X(A, B) \to X(B) \) whose fiber (over a well-chosen point of \( X(B) \)) can be identified with \( \text{Map}_{\text{Alg}_{\mathbb{E}_k}(\mathcal{C})}(A, B) \). In particular, every \( \mathbb{E}_k \)-algebra map \( f : A \to B \) determines a base point of the total space \( X(A, B) \), and the \( k \)-fold loop space \( \Omega^k X(A, B) \) can be identified with the space of units \( \mathcal{Z}_{\mathbb{E}_k}(f)^\times \) (see Definition 5.3.2.4 below). We therefore have a fiber sequence of spaces

\[
\text{Map}_{\text{Alg}_{\mathbb{E}_k}(\mathcal{C})}(A, B) \to X(A, B) \to X(B)
\]

which yields, after passing to loop spaces repeatedly, a fiber sequence

\[
\mathcal{Z}_{\mathbb{E}_k}(f)^\times \to B^\times \to \Omega^{k-1} \text{Map}_{\text{Alg}_{\mathbb{E}_k}(\mathcal{C})}(A, B).
\]

We should regard the map \( \phi \) as a \( k \)-dimensional analogue of the adjoint action of the unit group \( B^\times \) of an associative ring \( B \) on the set of maps \( \text{Hom}(A, B) \).

Our first step is to define the spaces of units appearing in the above discussion. This requires a bit of a digression.

**Definition 5.3.2.1.** Let \( \mathcal{O}^\odot \) be an \( \infty \)-operad, and let \( \mathcal{O}^\odot_{/\mathcal{S}} \subseteq \text{Fun}(\Delta^1, \mathcal{O}^\odot) \) be the \( \infty \)-category of pointed objects of \( \mathcal{O}^\odot \). The forgetful functor \( q : \mathcal{O}^\odot_{/\mathcal{S}} \to \mathcal{O}^\odot \) is a left fibration of simplicial sets. We let \( \chi_{\mathcal{O}} : \mathcal{O}^\odot \to \mathcal{S} \) denote a functor which classifies \( q \).

**Proposition 5.3.2.2.** Let \( q : \mathcal{O}^\odot \to \text{N}(\text{Fin}_k) \) be an \( \infty \)-operad and let \( \chi_{\mathcal{O}} : \mathcal{O}^\odot \to \mathcal{S} \) be as in Definition 5.3.2.1. Then \( \chi_{\mathcal{O}} \) is a \( \mathcal{O} \)-monoid object of \( \mathcal{S} \).

**Proof.** We must show that if \( X \in \mathcal{O}^\odot_{(n)} \), and if \( \alpha_i : X \to X_i \) are a collection of inert morphisms in \( \mathcal{O}^\odot \) lifting the maps \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) for \( 1 \leq i \leq n \), then the induced map \( \chi_{\mathcal{O}}(X) \to \prod_{1 \leq i \leq n} \chi_{\mathcal{O}}(X_i) \) is a homotopy equivalence. Let 0 denote a final object of \( \mathcal{O}^\odot \); then the left hand side is homotopy equivalent to \( \text{Map}_{\mathcal{O}^\odot}(0, X) \), while the right hand side is homotopy equivalent to \( \prod_{1 \leq i \leq n} \text{Map}_{\mathcal{O}^\odot}(0, X_i) \). The desired result now follows from the observation that the maps \( \alpha_i \) exhibit \( X \) as a \( q \)-product of the objects \( \{X_i\}_{1 \leq i \leq n} \).

**Remark 5.3.2.3.** An \( \infty \)-operad \( \mathcal{O}^\odot \) is unital if and only if the functor \( \chi_{\mathcal{O}} : \mathcal{O}^\odot \to \mathcal{S} \) is equivalent to the constant functor taking the value \( \Delta^0 \).

**Definition 5.3.2.4.** Let \( q : \mathcal{C}^\odot \to \mathcal{O}^\odot \) be a fibration of \( \infty \)-operads, where \( \mathcal{C}^\odot \) is unital, and let \( \chi_{\mathcal{C}} : \mathcal{C}^\odot \to \mathcal{S} \) be as in Definition 5.3.2.1. Composition with \( \chi_{\mathcal{C}} \) determines a functor \( \text{Alg}_{\mathcal{C}}(\mathcal{C}) \to \text{Mon}_{\mathcal{C}}(\mathcal{S}) \).

Suppose that \( \mathcal{O}^\odot = \mathcal{E}_k^\odot \), where \( k > 0 \). Since the collection of grouplike \( \mathcal{E}_k \)-spaces is stable under colimits in \( \text{Mon}_{\mathcal{E}_k}(\mathcal{S}) \) (Remark 5.2.6.9) the inclusion \( i : \text{Mon}_{\mathcal{E}_k}(\mathcal{S}) \subseteq \text{Mon}_{\mathcal{E}_k}(\mathcal{S}) \) preserves small colimits. It follows from Proposition 5.2.6.15 that \( \text{Mon}_{\mathcal{E}_k}(\mathcal{S}) \) is equivalent to \( S_{\mathbb{E}_k}^\infty \), and therefore presentable. Using Corollary T.5.5.2.9, we deduce that the inclusion functor \( i \) admits a right adjoint \( G \). We let \( \text{GL}_1 : \text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \to \text{Mon}_{\mathcal{E}_k}(\mathcal{S}) \) denote the composite functor

\[
\text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \xrightarrow{\chi_{\mathcal{C}}} \text{Mon}_{\mathcal{E}_k}(\mathcal{C}) \xrightarrow{G} \text{Mon}_{\mathcal{E}_k}(\mathcal{S}).
\]

If \( A \in \text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \), we will often write \( A^\times \) in place of \( \text{GL}_1(A) \); we will refer to \( A^\times \) as the \( \mathbb{E}_k \)-space of units in \( A \).

In the special case \( k = 0 \), we let \( \text{GL}_1 : \text{Alg}_{\mathcal{E}_k}(\mathcal{C}) \to \text{Mon}_{\mathcal{E}_k}(\mathcal{S}) \simeq \mathcal{S} \) be the functor defined by composition with \( \chi_{\mathcal{C}} \); we will also denote this functor by \( A \mapsto A^\times \).

We are now prepared to state our main result:
Theorem 5.3.2.5. Let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category. Assume that the underlying $\infty$-category $\mathcal{C}$ is presentable and that the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. Fix an integer $k \geq 0$, and let $Map : \Alg_{\mathcal{E}_k}(\mathcal{C})^{op} \times \Alg_{\mathcal{E}_k}(\mathcal{C}) \to S$ be the adjoint of the Yoneda embedding $\Alg_{\mathcal{E}_k}(\mathcal{C}) \to \Fun(\Alg_{\mathcal{E}_k}(\mathcal{C})^{op}, S)$. There exists another functor $X : \Alg_{\mathcal{E}_k}(\mathcal{C})^{op} \times \Alg_{\mathcal{E}_k}(\mathcal{C}) \to S$ and a natural transformation $\alpha : Map \to X$ with the following properties:

1. For every object $B \in \Alg_{\mathcal{E}_k}(\mathcal{C})$ and every morphism $f : A' \to A$ in $\Alg_{\mathcal{E}_k}(\mathcal{C})$, the diagram

$$
\begin{array}{ccc}
\text{Map}(A, B) & \longrightarrow & \text{Map}(A', B) \\
\downarrow & & \downarrow \\
X(A, B) & \longrightarrow & X(A', B)
\end{array}
$$

is a pullback square.

2. Let $f : A \to B$ be a morphism in $\Alg_{\mathcal{E}_k}(\mathcal{C})$, so that the map $f$ determines a base point of the space $X(A, B)$ (via $\alpha$). Then there is a canonical homotopy equivalence $\Omega^k X(A, B) \simeq \mathcal{F}_{\mathcal{E}_k}(f)^\times$.

Remark 5.3.2.6. In the situation of Theorem 5.3.2.5, it suffices to prove assertion (1) in the case where $A'$ is the initial object $1 \in \Alg_{\mathcal{E}_k}(\mathcal{C})$. This follows by applying Lemma T.4.4.2.1 to the diagram

$$
\begin{array}{ccc}
\text{Map}(A, B) & \longrightarrow & \text{Map}(A', B) & \longrightarrow & \text{Map}(1, B) \\
\downarrow & & \downarrow & & \downarrow \\
X(A, B) & \longrightarrow & X(A', B) & \longrightarrow & X(1, B).
\end{array}
$$

Remark 5.3.2.7. In the special case where $A'$ is the initial object $1 \in \Alg_{\mathcal{E}_k}(\mathcal{C})$, the space $\text{Map}(A', B)$ is contractible, so that part (1) of Theorem 5.3.2.5 asserts the existence of a fiber sequence

$$
\text{Map}(A, B) \to X(A, B) \to X(1, B).
$$

Fixing a base point $(f : A \to B) \in \text{Map}(A, B)$ and taking loop spaces repeatedly, we have a fiber sequence

$$
\Omega^k X(A, B) \to \Omega^k X(1, B) \to \Omega^{k-1} \text{Map}_{\Alg_{\mathcal{E}_k}(\mathcal{C})}(A, B)
$$

We observe that there is a canonical natural transformation $\beta : \mathcal{F}_{\mathcal{E}_k}(f_0) \to B$ of functors $\mathcal{E}_k^\otimes \to \mathcal{C}^\otimes$. The natural transformation $\beta$ induces an equivalence of $\mathcal{E}_k$-spaces $\mathcal{F}_{\mathcal{E}_k}(f_0)^\times \to B^\times$. Invoking part (2) of Theorem 5.3.2.5, we obtain the fiber sequence

$$
\mathcal{F}_{\mathcal{E}_k}(f)^\times \to B^\times \to \Omega^{k-1} \text{Map}_{\Alg_{\mathcal{E}_k}(\mathcal{C})}(A, B)
$$

described in (c).

An $\mathcal{E}_k$-algebra object $A$ of a symmetric monoidal $\infty$-category $\mathcal{C}$ determines an $(\infty, k)$-category $C(A)$ enriched over $\mathcal{C}$ (having a single $j$-morphism for each $j < k$). One approach to the proof of Theorem 5.3.2.5 would be to define $X(A, B)$ to be the space of functors from $C(A)$ into $C(B)$. Since we have not developed the theory of enriched $(\infty, k)$-categories in this book, our proof will proceed along somewhat different lines. We will use an inductive approach, which iteratively replaces the $\infty$-category $\mathcal{C}$ by the $\infty$-category $\text{LMod}_{\mathcal{C}}$ of $\infty$-categories left-tensored over $\mathcal{C}$. To guarantee that this replacement does not destroy our hypothesis that $\mathcal{C}$ is presentable, we need to introduce a few restrictions on the $\mathcal{C}$-modules that we allow.

Notation 5.3.2.8. Let $\kappa$ be a regular cardinal. Recall that a presentable $\infty$-category $\mathcal{C}$ is $\kappa$-compactly generated if $\mathcal{C}$ is generated by its $\kappa$-compact objects under the formation of small, $\kappa$-filtered colimits (see
If $\mathcal{C}$ and $\mathcal{D}$ are $\kappa$-compactly generated $\infty$-categories, then we will say that a functor $F : \mathcal{C} \to \mathcal{D}$ is $\kappa$-good if $F$ preserves small colimits and carries $\kappa$-compact objects of $\mathcal{C}$ to $\kappa$-compact objects of $\mathcal{D}$. Equivalently, $F$ is $\kappa$-good if $F$ admits a right adjoint $G$ which commutes with $\kappa$-filtered colimits (Proposition T.5.5.7.2).

Let $\Pr_\infty^L$ denote the $\infty$-category of presentable $\infty$-categories and colimit-preserving functors. We let $\Pr_{\kappa}^L$ denote the subcategory of the $\infty$-category $\Pr_\infty^L$ whose objects are $\kappa$-compactly generated presentable $\infty$-categories and whose morphisms are $\kappa$-good functors.

**Lemma 5.3.2.9.** Let $\kappa$ be a regular cardinal. Then:

1. Let $\mathcal{K}$ denote the collection of all $\kappa$-small simplicial sets together with the simplicial set $\text{Idem}$ introduced in §T.4.4.5. Then the functor $\mathcal{C} \mapsto \text{Ind}_\kappa^0(\mathcal{C})$ determines an equivalence of $\infty$-categories from $\text{Cat}_\infty^0(\mathcal{K})$ to $\Pr_{\kappa}^L$.
2. The $\infty$-category $\Pr_{\kappa}^L$ is presentable.
3. The inclusion functor $\Pr_{\kappa}^L \hookrightarrow \Pr_\infty^L$ preserves small colimits.

**Remark 5.3.2.10.** In the situation of Lemma 5.3.2.9, the objects of $\text{Cat}_\infty^0(\mathcal{K})$ are idempotent complete $\infty$-categories which admit $\kappa$-small colimits, and the morphisms in $\text{Cat}_\infty^0(\mathcal{K})$ are functors which preserve $\kappa$-small colimits. If $\kappa$ is uncountable, then the requirement of idempotent completeness is automatically satisfied.

**Proof.** We will prove assertion (1); assertion (2) will then follow from (1) and Lemma 4.8.4.2, and assertion (3) from the observation that the functor $\text{Ind}_\kappa : \text{Cat}_\infty(\mathcal{K}) \to \Pr_\kappa^L$ preserves small colimits. It is clear that the functor $\text{Ind}_\kappa : \text{Cat}_\infty^0(\mathcal{K}) \to \Pr_\kappa^L$ is essentially surjective. To prove that it is fully faithful, it will suffice to show that for every pair of $\infty$-categories $\mathcal{C}, \mathcal{D} \in \text{Cat}_\infty^0(\mathcal{K})$, the canonical map $\theta : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\text{Ind}_\kappa(\mathcal{C}), \text{Ind}_\kappa(\mathcal{D}))$ induces an equivalence of $\infty$-categories from the full subcategory $\text{Fun}^0((\mathcal{C}, \mathcal{D})$ of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the those functors which preserve $\mathcal{K}$-indexed colimits to the full subcategory $\text{Fun}^0((\text{Ind}_\kappa(\mathcal{C}), \text{Ind}_\kappa(\mathcal{D}))$ of $\text{Fun}(\text{Ind}_\kappa(\mathcal{C}), \text{Ind}_\kappa(\mathcal{D}))$ spanned by the $\kappa$-good functors. Let $\text{Fun}^0(\mathcal{C}, \text{Ind}_\kappa(\mathcal{D}))$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \text{Ind}_\kappa(\mathcal{D}))$ consisting of those functors which preserve $\mathcal{K}$-indexed colimits and carry $\mathcal{C}$ into the full subcategory of $\text{Ind}_\kappa(\mathcal{D})$ spanned by the $\kappa$-compact objects. We have a homotopy commutative diagram of $\infty$-categories:

$$
\begin{array}{ccc}
\text{Fun}^0((\mathcal{C}, \mathcal{D})) & \xrightarrow{\theta} & \text{Fun}^0((\text{Ind}_\kappa(\mathcal{C}), \text{Ind}_\kappa(\mathcal{D})) \\
\downarrow{\theta'} & & \downarrow{\theta''} \\
\text{Fun}(\mathcal{C}, \text{Ind}_\kappa(\mathcal{D}))
\end{array}
$$

where $\theta'$ and $\theta''$ are given by composing with the Yoneda embeddings for $\mathcal{D}$ and $\mathcal{C}$, respectively. To complete the proof, it will suffice to show that $\theta'$ and $\theta''$ are categorical equivalences.

To show that $\theta'$ is a categorical equivalence, let $\mathcal{D}'$ denote the collection of all $\kappa$-compact objects of $\text{Ind}_\kappa(\mathcal{D})$. Since $\mathcal{D}'$ is stable under $\kappa$-small colimits in $\text{Ind}_\kappa(\mathcal{D})$, $\text{Fun}^0((\mathcal{C}, \text{Ind}_\kappa(\mathcal{D}))$ is isomorphic to the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D}')$ spanned by those functors which preserve $\kappa$-small colimits. It will therefore suffice to show that the Yoneda embedding induces an equivalence $\mathcal{D} \to \mathcal{D}'$. This follows from Lemma T.5.4.2.4, by virtue of our assumption that $\mathcal{D}$ is idempotent-complete.

Repeating the previous argument with $\mathcal{C}$ in place of $\mathcal{D}$, we see that an object of $\text{Ind}_\kappa(\mathcal{C})$ is $\kappa$-compact if and only if it lies in the image of the Yoneda embedding $j : \mathcal{C} \to \text{Ind}_\kappa(\mathcal{C})$. Consequently, to prove that $\theta''$ is a categorical equivalence, it suffices to show that composition with $j$ induces an equivalence from the full subcategory of $\text{Fun}(\text{Ind}_\kappa(\mathcal{C}), \text{Ind}_\kappa(\mathcal{E}))$ spanned by those functors which preserve small colimits to the full subcategory of $\text{Fun}(\mathcal{C}, \text{Ind}_\kappa(\mathcal{E}))$ spanned by those functors which preserve $\kappa$-small colimits; this follows from Proposition T.5.5.1.9.

We now study the interaction between the subcategory $\Pr_{\kappa}^L \subseteq \Pr_\infty^L$ and the symmetric monoidal structure $\Pr_\infty^{L \otimes}$ on $\Pr_\infty^L$ constructed in §4.8.1. Let $\Pr_{\kappa}^{L \otimes}$ denote the subcategory of $\Pr_\infty^{L \otimes}$ whose objects are finite...
sequences \((\mathcal{C}_1, \ldots, \mathcal{C}_n)\) where each of the \(\infty\)-categories \(\mathcal{C}_i\) is \(\kappa\)-compactly generated, and whose morphisms are given by maps \((\mathcal{C}_1, \ldots, \mathcal{C}_n) \to (\mathcal{D}_1, \ldots, \mathcal{D}_n)\) covering a map \(\alpha : \langle m \rangle \to \langle n \rangle\) in \(\text{Fin}_*\) such that the functors \(\prod_{\alpha(i) = j} \mathcal{C}_i \to \mathcal{D}_j\) preserve \(\kappa\)-compact objects for \(1 \leq j \leq n\).

**Lemma 5.3.2.11.** Let \(\kappa\) be a regular cardinal. Then:

1. If \(\mathcal{C}\) and \(\mathcal{D}\) are \(\kappa\)-compactly generated presentable monoidal \(\infty\)-categories, then \(\mathcal{C} \otimes \mathcal{D}\) is \(\kappa\)-compactly presented. Moreover, the collection of \(\kappa\)-compact objects of \(\mathcal{C} \otimes \mathcal{D}\) is generated under \(\kappa\)-small colimits by tensor products of the form \(C \otimes D\), where \(C \in \mathcal{C}\) and \(D \in \mathcal{D}\) are \(\kappa\)-compact.

2. The composite map \(\mathcal{P}r^\otimes_k \subseteq \mathcal{P}r^L_k \to N(\text{Fin}_*)\) exhibits \(\mathcal{P}r^L_k\) as a symmetric monoidal \(\infty\)-category, and the inclusion \(\mathcal{P}r^L_k \subseteq \mathcal{P}r^{L\otimes}_k\) is a symmetric monoidal functor.

3. Let \(\mathcal{X}\) be as in Lemma 5.3.2.9. The functor \(\text{Ind}_k\) induces an equivalence of symmetric monoidal \(\infty\)-categories \(\text{Cat}_\infty(\mathcal{X}^\otimes) \to \mathcal{P}r^L_k\).

4. The tensor product \(\otimes : \mathcal{P}r^L_k \times \mathcal{P}r^L_k \to \mathcal{P}r^L_k\) preserves small colimits separately in each variable.

**Proof.** Remark 4.8.1.8 implies that the functor \(\text{Ind}_k : \text{Cat}_\infty(\mathcal{X}^\otimes) \to \mathcal{P}r^L\) extends to a symmetric monoidal functor. To prove (1), we note that if \(\mathcal{C} \simeq \text{Ind}_k(\mathcal{C}_0)\) and \(\mathcal{D} \simeq \text{Ind}_k(\mathcal{D}_0)\), then \(\mathcal{C} \otimes \mathcal{D} \simeq \text{Ind}_k(\mathcal{C}_0 \otimes \mathcal{D}_0)\) is a \(\kappa\)-compactly generated \(\infty\)-category. To prove the second assertion of (1), it suffices to show that \(\mathcal{C}_0 \otimes \mathcal{D}_0\) is generated under \(\kappa\)-small colimits by the essential image of the functor \(\mathcal{C}_0 \times \mathcal{D}_0 \to \mathcal{C}_0 \otimes \mathcal{D}_0\), which is clear. Assertion (2) follows immediately from (1). Assertion (3) follows from Lemma 5.3.2.9, and assertion (4) follows from (3) together with Lemma 4.4.8.2.

**Lemma 5.3.2.12.** Let \(\mathcal{C}^\otimes\) be a symmetric monoidal \(\infty\)-category. Assume that \(\mathcal{C}\) is presentable and that the tensor product \(\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}\) preserves small colimits separately in each variable. Then there exists an uncountable regular cardinal \(\kappa\) with the following properties:

1. The \(\infty\)-category \(\mathcal{C}\) is \(\kappa\)-compactly generated.

2. The tensor product \(\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}\) preserves \(\kappa\)-compact objects, and the unit object \(1 \in \mathcal{C}\) is \(\kappa\)-compact.

3. For every algebra object \(A \in \text{Alg}(\mathcal{C})\), the \(\infty\)-category \(\text{RMod}_A(\mathcal{C})\) is \(\kappa\)-compactly generated.

4. For every algebra object \(A \in \text{Alg}(\mathcal{C})\), the action functor \(\otimes : \mathcal{C} \times \text{RMod}_A(\mathcal{C}) \to \text{RMod}_A(\mathcal{C})\) preserves \(\kappa\)-compact objects.

**Proof.** Choose an regular cardinal \(\kappa_0\) such that \(\mathcal{C}\) is \(\kappa_0\)-compactly generated. Let \(\mathcal{C}_0\) be the full subcategory of \(\mathcal{C}\) spanned by the \(\kappa_0\)-compact objects, and let \(\mathcal{C}_1\) denote the smallest full subcategory of \(\mathcal{C}\) which contains \(\mathcal{C}_0\), the unit object of \(\mathcal{C}\), and the essential image of the tensor product functor \(\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}\). Since \(\mathcal{C}_1\) is essentially small, there exists a regular cardinal \(\kappa > \kappa_0\) such that every object in \(\mathcal{C}_1\) is \(\kappa\)-small. We claim that \(\kappa\) has the desired properties. It is clear that \(\kappa\) is uncountable and that (1) is satisfied.

To prove (2), choose \(\kappa\)-compact objects \(C, D \in \mathcal{C}\). Then \(C \otimes D\) can be written as \(\kappa\)-small colimits \(\lim_{\alpha} (C_{\alpha})\) and \(\lim_{\beta} (D_{\beta})\), where the objects \(C_{\alpha}\) and \(D_{\beta}\) are \(\kappa_0\)-compact. Then \(C \otimes D \simeq \lim_{\alpha, \beta} (C_{\alpha} \otimes D_{\beta})\) is a \(\kappa\)-small colimit of objects belonging to \(\mathcal{C}_1\), and is therefore \(\kappa\)-compact.

We now prove (3). According to Corollary 4.2.3.5, the forgetful functor \(G : \text{RMod}_A(\mathcal{C}) \to \mathcal{C}\) preserves \(\kappa\)-filtered colimits (in fact, all small colimits). It follows from Proposition T.5.5.7.2 that the left adjoint \(F\) to \(G\) preserves \(\kappa\)-compact objects. Let \(X\) denote the full subcategory of \(\text{RMod}_A(\mathcal{C})\) generated under small colimits by objects of the form \(F(C)\), where \(C \in \mathcal{C}\) is \(\kappa\)-compact; we will show that \(X = \text{RMod}_A(\mathcal{C})\). For each \(M \in \text{RMod}_A(\mathcal{C})\), we can write \(M \simeq A \otimes_A M = |\text{Bar}_A(A, M)|\). Consequently, to show that \(M \in X\), it will suffice to show that \(X\) contains \(F(A \otimes_n M)\) for each \(n \geq 1\). We are therefore reduced to proving that \(F(C) \in X\) for each \(C \in \mathcal{C}\), which is clear (the functor \(F\) preserves small colimits and \(C\) can be written as a colimit of \(\kappa\)-compact objects of \(\mathcal{C}\) by (1)).
We now prove (4). Let $\mathcal{Y}$ denote the full subcategory of $\text{RMod}_A(\mathcal{C})$ spanned by those objects $M$ such that $C \otimes M \in \text{RMod}_A(\mathcal{C})$ is $\kappa$-compact for every $\kappa$-compact object $C \in \mathcal{C}$. The $\infty$-category $\mathcal{Y}$ is evidently closed under $\kappa$-small colimits in $\text{RMod}_A(\mathcal{C})$. Since $C \otimes F(D) \simeq F(C \otimes D)$, it follows from (2) that $\mathcal{Y}$ contains $F(D)$ for every $\kappa$-compact object $D \in \mathcal{C}$. Since every object of $\mathcal{Y}$ is $\kappa$-compact in $\text{RMod}_A(\mathcal{C})$, we have a fully faithful embedding $f : \text{Ind}_A(\mathcal{Y}) \to \text{Mod}_A^H(\mathcal{E})$, which preserves small colimits by Proposition T.5.5.1.9. The essential image $\mathcal{Y}'$ of $f$ is stable under small colimits and contains $F(D)$ for every $\kappa$-compact object $D \in \mathcal{C}$, so that $X \subseteq \mathcal{Y}'$. It follows that $f$ is essentially surjective and therefore an equivalence of $\infty$-categories. Lemma T.5.4.2.4 now guarantees that the collection of $\kappa$-compact objects of $\text{RMod}_A(\mathcal{C})$ is an idempotent completion of $\mathcal{Y}$. Since $\mathcal{Y}$ is uncountable, $\mathcal{Y}$ is stable under sequential colimits and therefore idempotent complete. It follows that $\mathcal{Y}$ contains every $\kappa$-compact object of $\text{RMod}_A(\mathcal{C})$, as desired.  

We now proceed with the proof of our main result.

**Proof of Theorem 5.3.2.5.** We proceed by induction on $k$. Assume first that $k = 0$. Let $X$ denote the composite functor

$$
\text{Alg}_{\text{G}}(\mathcal{C})^{\text{op}} \times \text{Alg}_{\text{E}}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \times \mathcal{C} \xrightarrow{H} \mathcal{S},
$$

where $H$ is the adjoint of the Yoneda embedding for $\mathcal{C}$ (given informally by $H(C, C') = \text{Map}_\mathcal{C}(C, C')$). The forgetful functor $\theta : \text{Alg}_{\text{E}}(\mathcal{C}) \to \mathcal{C}$ determines a natural transformation of functors $\text{Map} \to X$. We claim that this functor satisfies conditions (1) and (2) of Theorem 5.3.2.5.

Suppose we are given a morphism $A' \to A$ in $\text{Alg}_{\text{G}}(\mathcal{C})$ and an object $B \in \text{Alg}_{\text{E}}(\mathcal{C})$. Let $\mathbf{1}$ denote the unit object of $\mathcal{E}_\mathbf{1}$. Proposition 2.1.3.9 implies that $\text{Alg}_{\text{G}}(\mathcal{C})$ is equivalent to $(\mathcal{E})^{1/}$. It follows that we have a natural transformation of fiber sequences

$$
\begin{array}{ccc}
\text{Map}(A, B) & \xrightarrow{\phi} & \text{Map}(A', B) \\
\downarrow & & \downarrow \\
\text{X}(A, B) & \xrightarrow{\phi} & \text{X}(A', B) \\
\downarrow & & \downarrow \\
\text{Map}_{\mathcal{C}}(\mathbf{1}, \theta(B)) & \xrightarrow{\phi} & \text{Map}_{\mathcal{C}}(\mathbf{1}, \theta(B)).
\end{array}
$$

Since the bottom horizontal map is a homotopy equivalence, the upper square is a homotopy pullback square. This proves (1). To prove (2), we invoke Corollary 5.3.1.31 to identify $\mathcal{Z}_\mathbf{1}((f) \times) = \text{Map}_{\mathcal{C}}(\mathbf{1}, \mathcal{Z}_\mathbf{1}((f) \times))$ with the mapping space $\text{Map}_{\mathcal{C}}(\theta(A), \theta(B)) = X(A, B)$.

We now treat the case where $k > 0$. Applying Corollary 5.1.2.6 (in the setting of $\infty$-categories which are not necessarily small, which admit small colimits) we obtain a fully faithful embedding $\psi : \text{Alg}_{\text{G}}(\mathcal{C}) \to \text{Alg}_{\text{G}_{k-1}}(\mathcal{C}_{\text{op}}(\mathcal{P}n))$. Let $\kappa$ be an uncountable regular cardinal satisfying the conditions of Lemma 5.3.2.12 and let $\mathcal{C}' = \text{Mod}_\mathcal{C}(\mathcal{P}_n)$. Using Corollary 4.2.3.7, Lemma 5.3.2.9, and Lemma 5.3.2.11, we deduce that $\mathcal{C}'$ is a presentable $\infty$-category equipped with a symmetric monoidal structure, such that the tensor product $\otimes : \mathcal{C}' \times \mathcal{C}' \to \mathcal{C}'$ preserves colimits separately in each variable. The functor $\psi$ induces a fully faithful embedding $\text{Alg}_{\text{G}}(\mathcal{C}) \to \text{Alg}_{\text{G}_{k-1}}(\mathcal{C'}_{\text{op}})$, which we will also denote by $\psi$.

Let $\text{Map}' : \text{Alg}_{\text{G}_{k-1}}(\mathcal{C}')^{\text{op}} \times \text{Alg}_{\text{G}_{k-1}}(\mathcal{C}') \to \mathcal{S}$ be the adjoint to the Yoneda embedding. Invoking the inductive hypothesis, we deduce that there exists another functor $X' : \text{Alg}_{\text{G}_{k-1}}(\mathcal{C}')^{\text{op}} \times \text{Alg}_{\text{G}_{k-1}}(\mathcal{C'}) \to \mathcal{S}$ and a natural transformation $\alpha' : \text{Map}' \to X'$ satisfying hypotheses (1) and (2) for the $\infty$-category $\mathcal{C}'$. Let $X$ denote the composition

$$
\text{Alg}_{\text{G}}(\mathcal{C})^{\text{op}} \times \text{Alg}_{\text{G}}(\mathcal{C}) \xrightarrow{\psi \times \psi} \text{Alg}_{\text{G}_{k-1}}(\mathcal{C}')^{\text{op}} \times \text{Alg}_{\text{G}_{k-1}}(\mathcal{C'}) \xrightarrow{X'} \mathcal{S}.
$$

Since $\psi$ is fully faithful, the composition

$$
\text{Alg}_{\text{G}}(\mathcal{C})^{\text{op}} \times \text{Alg}_{\text{G}}(\mathcal{C}) \xrightarrow{\psi \times \psi} \text{Alg}_{\text{G}_{k-1}}(\mathcal{C}')^{\text{op}} \times \text{Alg}_{\text{G}_{k-1}}(\mathcal{C'}) \xrightarrow{\text{Map}' \times \text{Map}'} \mathcal{S}
$$
Applying the (symmetric monoidal) functor \( \psi \), we obtain a diagram

\[
\begin{array}{ccc}
\psi(Z) \otimes A & \xrightarrow{\psi(f)} & B, \\
A & \xrightarrow{f} & B.
\end{array}
\]

which is classified by a map \( \beta : \psi(Z) \to \mathfrak{Z}_{k-1}(\psi(f)) \). The inductive hypothesis guarantees a homotopy equivalence \( \mathfrak{Z}_{k-1}(\psi(f))^\times \simeq \Omega^{n-1}X'(A,B) \simeq \Omega^{n-1}X(A,B) \). Passing to loop spaces, we get an homotopy equivalence \( \Omega^3 \mathfrak{Z}_{k-1}(\psi(f))^\times \simeq \Omega^n X(A,B) \). We will complete the proof by showing the following:

(a) There is a canonical homotopy equivalence \( Z^\times \simeq \Omega \psi(Z)^\times \).

(b) The map \( \beta \) induces a homotopy equivalence \( \Omega \psi(Z)^\times \to \Omega^3 \mathfrak{Z}_{k-1}(\psi(f))^\times \).

Assertion (a) is easy: the space \( \Omega \psi(Z)^\times \) can be identified with the summand of the mapping space \( \text{Map}_{\text{RMod}_{(\mathcal{C})}}(Z,Z) \) spanned by the equivalences from \( Z \) to itself. Corollary 4.2.4.7 furnishes an identification \( \text{Map}_{\text{RMod}_{(\mathcal{C})}}(Z,Z) \simeq \text{Map}_{\mathcal{C}}(1,Z) \), under which the summand \( \Omega \psi(Z)^\times \subseteq \text{Map}_{\text{RMod}_{(\mathcal{C})}}(Z,Z) \) corresponds to the space of units \( Z^\times \).

The proof of (b) is slightly more involved. We wish to show that \( \beta \) induces a homotopy equivalence

\[ \phi : \Omega \text{Map}_{\text{RMod}_{(\mathcal{C})}}(\mathcal{C}, \text{RMod}_{Z}(\mathcal{C})) \to \Omega \text{Map}_{\text{RMod}_{(\mathcal{C})}}(\mathcal{C}, \mathfrak{Z}_{k-1}(\psi(f))) \].

Let \( \mathcal{D}^\circ \) be a unitalization of the symmetric monoidal \( \infty \)-category \( \text{Mod}_{\mathcal{C}}(\mathcal{P}_{\mathcal{L}})^\circ \), so that the underlying \( \infty \)-category of \( \mathcal{D} \) is equivalent to \( \text{Mod}_{\mathcal{C}}(\mathcal{P}_{\mathcal{L}})^\circ \). Since \( \mathfrak{Z}_{k-1} \) is unital, we can regard \( \text{RMod}_{Z}(\mathcal{C}) \) and \( \mathfrak{Z}_{k-1}(\psi(f)) \) as \( \mathbb{E}_{k-1} \)-algebra objects of \( \mathcal{D} \). Regard the \( \infty \)-category \( \text{Mod}_{\mathcal{C}}(\mathcal{P}_{\mathcal{L}})^\circ \) as tensored over spaces, and let \( D = \mathcal{C} \otimes S^1 \) (see §T.4.4.4), regarded as an object of \( \mathcal{D} \) by choosing a base point \( * \in S^1 \). Then we can identify \( \phi \) with the morphism \( \text{Map}_{\mathcal{D}}(D, \text{RMod}_{Z}(\mathcal{C})) \to \text{Map}_{\mathcal{D}}(D, \mathfrak{Z}_{k-1}(\psi(f))) \).

Theorem 4.8.5.5 guarantees that the construction \( C \to \text{RMod}_{C}(\mathcal{C}) \) determines a fully faithful embedding of symmetric monoidal \( \infty \)-categories \( F : \text{Alg}(\mathcal{C})^\circ \to \mathcal{D}^\circ \). Theorem 4.8.5.11 guarantees that the underlying functor \( f : \text{Alg}(\mathcal{C}) \to \mathcal{D} \) admits a right adjoint \( g \), so that \( f \) exhibits \( \text{Alg}(\mathcal{C}) \) as a colocalization of \( \mathcal{D} \) which is stable under tensor products in \( \mathcal{D} \). Using Proposition 2.2.1.1, we see that \( g \) can be regarded as a lax symmetric monoidal functor, and induces a map \( \gamma : \text{Alg}_{\mathbb{E}_1}(\mathcal{C}) \simeq \text{Alg}_{\mathfrak{Z}_{k-1}}(\mathcal{C}) \to \text{Alg}_{\mathfrak{Z}_{k-1}}(\mathcal{D}) \) which is right adjoint to the functor given by composition with \( F \). Using the fact that \( \psi \) is a fully faithful symmetric monoidal functor, we deduce that \( \gamma(\beta) \) is an equivalence in \( \text{Alg}_{\mathbb{E}_1}(\mathcal{C}) \). Consequently, to prove that \( \phi \) induces an equivalence from \( \text{Map}_{\mathcal{D}}(D, \text{Mod}_{\mathcal{C}}(\mathcal{P}_{\mathcal{L}})^\circ(\mathcal{C})) \) to \( \text{Map}_{\mathcal{D}}(D, \mathfrak{Z}_{k-1}(\psi(f))) \), it will suffice to show that the object \( D \in \mathbb{E}_1 \) lies in the essential image of the functor \( f \). In other words, we must show that there exists an algebra object \( K \in \text{Alg}(\mathcal{C}) \) such that \( \mathcal{C} \otimes S^1 \) is equivalent to \( \text{RMod}_{K}(\mathcal{C}) \) in the \( \infty \)-category \( \text{Mod}_{\mathcal{C}}(\mathcal{P}_{\mathcal{L}})^\circ \). Choosing a symmetric monoidal functor \( S^2 \to \mathcal{C}^\circ \) (which is well-defined up to a contractible space of choices), we can reduce to the case where \( \mathcal{C} = \mathcal{S} \), endowed with the Cartesian symmetric monoidal structure. In this case, \( \text{Mod}_{\mathcal{C}}(\mathcal{P}_{\mathcal{L}})^\circ \) is equivalent to the \( \infty \)-category \( \mathcal{P}_{\mathcal{L}}^\text{h} \) of symmetric monoidal \( \infty \)-categories, and the tensor product \( \mathcal{C} \otimes S^1 \) can be identified with the \( \infty \)-category \( (\mathcal{S})/S^1 \) of spaces fibered over the circle. In this case, we
can take $K = \mathbb{Z} \simeq \Omega(S^1) \in \text{Mon}(S) \simeq \text{Alg}(S)$ to be the group of integers: the equivalence $S_{/S^1} \simeq \text{Alg}_K(S)$ is provided by Remark 5.2.6.28, and the free module functor $S \to \text{Alg}_K(S)$ corresponds to the map given by the base point on $S^1$ by virtue of Remark 5.2.6.29.

**Warning 5.3.2.13.** The spaces $X(A, B)$ constructed in the proof of Theorem 5.3.2.5 depend on the regular cardinals $\kappa$ that are chosen at each stage of the induction. We can eliminate this dependence by replacing the functor $X$ by the essential image of the natural transformation $\alpha : \text{Map} \to X$ at each step.

**Remark 5.3.2.14.** With a bit more effort, one can show that the homotopy equivalence $\Omega^k X(A, B) \simeq Z_{\mathbb{E}}(f)^{\times}$ appearing in Theorem 5.3.2.5 is an equivalence of $k$-fold loop spaces, which depends functorially on $A$ and $B$.

### 5.3.3 Tensor Products of Free Algebras

Let $\mathcal{O}^\otimes$ be any $\infty$-operad, and let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category. Applying Construction 3.2.4.1 to the evident bifunctor of $\infty$-operads $\mathcal{O}^\otimes \times \text{N}(\text{Fin}_n) \to \text{N}(\text{Fin}_n)$, we deduce that the $\infty$-category $\text{Alg}_\mathcal{O}(\mathcal{C})$ admits a symmetric monoidal structure (see Proposition 3.2.4.3), given by pointwise tensor product: for $A, B \in \text{Alg}_\mathcal{O}(\mathcal{C})$ and $X \in \mathcal{O}$, we have $(A \otimes B)(X) \simeq A(X) \otimes B(X)$.

In the special case where $\mathcal{O}^\otimes = \text{N}(\text{Fin}_n)$ is the commutative $\infty$-operad, the tensor product $A \otimes B$ can be identified with the coproduct of $A$ and $B$ in the $\infty$-category $\text{Alg}_\mathcal{O}(\mathcal{C}) = \text{CA}l(\mathcal{C})$ (Proposition 3.2.4.7). For other $\infty$-operads, this is generally not the case. Suppose, for example, that $\mathcal{O}^\otimes$ is the associative $\infty$-operad, and that $\mathcal{C}$ is the (nerve of the) ordinary category $\text{Vect}_\mathbb{C}$ of vector spaces over the field $\mathbb{C}$ of complex numbers. Then $\text{Alg}_{\text{Ass}}(\mathcal{C})$ is equivalent to the nerve of the category of associative $\mathbb{C}$-algebras $A$ and $B$, there is a diagram of associative algebras

$$A \to A \otimes_{\mathbb{C}} B \leftarrow B,$$

but this diagram does not exhibit $A \otimes_{\mathbb{C}} B$ as a coproduct of $A$ and $B$. Instead, it exhibits $A \otimes_{\mathbb{C}} B$ as the quotient of the coproduct $A \amalg B$ by the (two-sided) ideal generated by commutators $[a, b] = ab - ba$, where $a \in A$ and $b \in B$. In other words, $A \otimes_{\mathbb{C}} B$ is freely generated by $A$ and $B$ subject to the condition that $A$ and $B$ commute in $A \otimes_{\mathbb{C}} B$.

In this section, we will prove an $\infty$-categorical generalization of the above assertion. We will replace the ordinary category $\text{Vect}_\mathbb{C}$ by an arbitrary symmetric monoidal $\infty$-category $\mathcal{C}$ and the associative $\infty$-operad $\text{Ass}$ by any coherent $\infty$-operad $\mathcal{O}^\otimes$ for which the Kan complex $\mathcal{O}$ is contractible.

**Notation 5.3.3.1.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex. Fix a pair of objects $X \in \mathcal{O}$ and $Y \in \mathcal{O}^\otimes_{(2)}$. We let $\text{Bin}(\mathcal{O})$ denote the summand of $\text{Map}_{\mathcal{O}^\otimes}(Y, X)$ consisting of active morphisms from $Y$ to $X$. We will refer to $\text{Bin}(\mathcal{O})$ as the space of binary operations in $\mathcal{O}$ (note that since $\mathcal{O}$ is contractible, the space $\text{Bin}(\mathcal{O})$ is canonically independent of the objects $X$ and $Y$).

Let $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a $\mathcal{O}$-monoidal $\infty$-category. For every point $\eta \in \text{Bin}(\mathcal{O})$, we obtain a map

$$\mathcal{C} \times \mathcal{C} \simeq \mathcal{C}^\otimes_Y \twoheadrightarrow \mathcal{C}^\otimes_X \simeq \mathcal{C}.$$ 

We will refer to this map as the tensor product determined by $\eta$ and denote it by $\otimes_\eta : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$. Note that the tensor product $C \otimes_\eta D$ depends functorially on the triple $(C, D, \eta)$. If $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$, then evaluation at $\eta$ determines a map $A \otimes_\eta A \to A$ (where we abuse notation by identifying $A$ with its image under the forgetful functor $\text{Alg}_{/\mathcal{O}}(\mathcal{C}) \to \text{Fun}_\mathcal{O}(\mathcal{O}, \mathcal{C}) \simeq \mathcal{C}$).

**Example 5.3.3.2.** Let $\mathcal{O}^\otimes = \mathbb{E}_k^\otimes$ for $0 \leq k \leq \infty$. Then the space of binary operations $\text{Bin}(\mathcal{O})$ can be identified with the space of rectilinear embeddings $\Omega^k \amalg \Omega^k \to \square^k$, which is homotopy equivalent to a sphere $S^{k-1}$ (see Lemma 5.1.1.3). We single out three special cases:

- If $k = 0$, then $\text{Bin}(\mathcal{O})$ is empty.
If $k = 1$, then $\text{Bin}(\emptyset)$ is homotopy equivalent to the sphere $S^0$. If $\mathcal{C}$ is an $E_1$-monoidal $\infty$-category, then the corresponding tensor product operations on $\mathcal{C}$ are given by $(C, D) \mapsto C \otimes D$ and $(C, D) \mapsto D \otimes C$.

If $k = \infty$, then the space of operations $\text{Bin}(\emptyset)$ is contractible.

Let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category which admits small colimits, and assume that the tensor product on $\mathcal{C}$ preserves small colimits separately in each variable. Let $\mathcal{O}^\otimes$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex. Then the forgetful functor $\text{Alg}_{\mathcal{O}}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint $\text{Free} : \mathcal{C} \to \text{Alg}_{\mathcal{O}}(\mathcal{C})$ (Corollary 3.1.3.5). Given a pair of objects $C, D \in \mathcal{C}$, the tensor product $\text{Free}(C) \otimes \text{Free}(D)$ is generally not equivalent to the coproduct $\text{Free}(C) \amalg \text{Free}(D)$.

To measure the difference, we note that every binary operation $\eta \in \text{Mul}(\mathcal{O})$ gives rise to a map

$$f_\eta : C \otimes D \to \text{Free}(C \amalg D) \otimes \text{Free}(C \amalg D) \xrightarrow{\text{Free}(\amalg)(\eta)} \text{Free}(C \amalg D).$$

Note that the composite map $C \otimes D \to \text{Free}(C \amalg D) \xrightarrow{\eta} \text{Free}(C) \otimes \text{Free}(D)$ does not depend on the point $\eta$. Allowing $\eta$ to vary, we obtain a map

$$f : (C \otimes D) \otimes \text{Bin}(\emptyset) \to \text{Free}(C \amalg D)$$

in $\mathcal{C}$, where we regard $\mathcal{C}$ as tensored over the $\infty$-category $S$ of spaces as explained in §T.4.4.4. Equivalently, we can view $f$ as a map

$$\text{Free}(C \otimes D \otimes \text{Bin}(\emptyset)) \to \text{Free}(C \amalg D),$$

which fits into a diagram

$\text{Free}(C \otimes D \otimes \text{Bin}(\emptyset)) \quad \text{Free}(C \otimes D) \quad \text{Free}(C \amalg D) \quad \text{Free}(C) \otimes \text{Free}(D).$

The commutativity of this diagram encodes the fact that $g \circ f_\eta$ is independent of $f$; equivalently, it reflects the idea that $C$ and $D$ “commute” inside the tensor product $\text{Free}(C) \otimes \text{Free}(D)$. The main result of this section can be formulated as follows:

**Theorem 5.3.3.3.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category which admits small colimits and assume that the tensor product on $\mathcal{C}$ preserves small colimits separately in each variable. Let $\mathcal{O}^\otimes$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex, and let $\text{Free} : \mathcal{C} \to \text{Alg}_{\mathcal{O}}(\mathcal{C})$ be a left adjoint to the forgetful functor. If $\mathcal{O}^\otimes$ is coherent, then for every pair of objects $C, D \in \mathcal{C}$, the construction sketched above gives rise to a pushout diagram

$$\text{Free}(C \otimes D \otimes \text{Bin}(\emptyset)) \to \text{Free}(C \amalg D) \to \text{Free}(C) \otimes \text{Free}(D)$$

in $\text{Alg}_{\mathcal{O}}(\mathcal{C})$.

**Remark 5.3.3.4.** In the statement of Theorem 5.3.3.3, it is possible to weaken the hypothesis that $\mathcal{C}$ admits small colimits: it suffices that $\mathcal{C}$ admits sufficiently many colimits for all of the relevant constructions to be well-defined. For example, if $\kappa$ is an uncountable regular cardinal for which $\mathcal{O}^\otimes$ is $\kappa$-small, then it suffices to assume that $\mathcal{C}$ admits $\kappa$-small colimits and that the tensor product

$$\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$$

preserves $\kappa$-small colimits separately in each variable. In the special case $\mathcal{O}^\otimes = E_k^\otimes$ for $0 \leq k \leq \infty$, it suffices to assume that $\mathcal{C}$ admits countable colimits and that the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves countable...
colimits separately in each variable. These stronger versions of Theorem 5.3.3.3 follow from the proof that we will give in this section. Alternatively, they can be deduced formally from Theorem 5.3.3.3 by enlarging the ∞-category C, using the formalism described in §4.8.1.

Note that the hypotheses of Theorem 5.3.3.3 are satisfied when O = E_k^∞ for 0 ≤ k ≤ ∞; see Theorem 5.1.1.1 (this is satisfied, for example, if O is the E_k-operad for 0 ≤ k ≤ ∞; this follows from Theorem 5.1.1.1 when k < ∞ and from Example 3.3.1.12 when k = ∞.

**Example 5.3.3.5.** Suppose that O = E_k^∞. In this case, we can identify the ∞-category Alg_O(C) with the ∞-category C_1 (Proposition 2.1.3.9); here 1 denotes the unit object of C, and the free algebra functor Free : C → Alg_O(C) is given by the formula C ↦ 1 ⊔ C. In this case, Theorem 5.3.3.3 asserts that the diagram

\[
\begin{array}{cccc}
1 & \rightarrow & 1 ⊔ C ⊔ D \\
\downarrow & & \downarrow \\
1 ⊔ (C ⊔ D) & \rightarrow & (1 ⊔ C) ⊔ (1 ⊔ D)
\end{array}
\]

is a pushout square. This follows immediately from the calculation

\[
\begin{array}{c}
(1 ⊔ C) ⊔ (1 ⊔ D) \simeq 1 ⊔ C ⊔ D ⊔ (C ⊔ D).
\end{array}
\]

**Example 5.3.3.6.** Suppose that O = E_1^∞ ≃ Ass^∞ (see Example 5.1.0.7). In this case, Theorem 5.3.3.3 is equivalent to the assertion that the diagram

\[
\begin{array}{ccc}
\text{Free}(C ⊔ D) & \xrightarrow{f} & \text{Free}(C) ⊔ \text{Free}(D) \\
\downarrow & & \downarrow \\
\text{Free}(C ⊔ D) & \rightarrow & \text{Free}(C) ⊔ \text{Free}(D)
\end{array}
\]

is a coequalizer, where f and g are induced by the maps C ⊔ D → Free(C) ⊔ Free(D) given by multiplication on Free(C) ⊔ Free(D) in the two possible orders.

**Example 5.3.3.7.** Let O = E_∞^∞ ≃ Comm, so that the space of binary operations Bin(Comm) is contractible. In this case, the left vertical map in the diagram

\[
\begin{array}{ccc}
\text{Free}(C ⊔ D ⊔ \text{Bin}(O)) & \rightarrow & \text{Free}(C) ⊔ \text{Free}(D) \\
\downarrow & & \downarrow \\
\text{Free}(C ⊔ D) & \rightarrow & \text{Free}(C) ⊔ \text{Free}(D)
\end{array}
\]

is an equivalence. Consequently, Theorem 5.3.3.3 reduces to the assertion that the right vertical map Free(C) ⊔ Free(D) → Free(C) ⊔ Free(D) is an equivalence, which is a special case of Proposition 3.2.4.7.

Let us now outline our approach to the proof of Theorem 5.3.3.3. Our first goal is to try to remove the hypothesis that the ambient ∞-category C is symmetric monoidal. We note that the theory of O-algebras can be developed in an arbitrary O-monoidal ∞-category. However, if we assume only that C is an O-monoidal ∞-category, then there is no monoidal structure on Alg_O(C). In particular, the tensor product Free(C) ⊔ Free(D) does not generally inherit the structure of an O-algebra. However, there are some special cases in which it does. For example, suppose that O = Ass and that there exists an equivalence α : D ⊔ C → C ⊔ D in the ∞-category C. In this case, we will see that the tensor product

\[
\text{Free}(C) ⊔ \text{Free}(D) \simeq \Pi_{m,n \geq 0} C^\otimes m \otimes D^\otimes n
\]

admits the structure of an algebra whose underlying multiplication is determined by the family of maps

\[
(C^\otimes m \otimes D^\otimes n) \otimes (C^\otimes m' \otimes D^\otimes n') \rightarrow C^\otimes m + m' \otimes D^\otimes n + n'
\]
given by applying \( \alpha \) iteratively.

More generally, suppose that \( \mathcal{C} \) is \( \mathcal{O} \)-monoidal. If we are given objects \( C, D \in \mathcal{C} \), we will say that \( C \) **commutes with** \( D \) if the map \( \eta \mapsto C \otimes_{\eta} D \) is nullhomotopic: that is, if there exists another object \( E \in \mathcal{C} \) and a family of equivalences

\[
\alpha_{\eta} : C \otimes_{\eta} D \simeq E
\]
depending functorially on \( \eta \in \text{Bin}(\mathcal{O}) \). In this case, we will construct another \( \mathcal{O} \)-algebra object \( \text{Free}(C) \otimes_{\alpha} \text{Free}(D) \). It will follow more or less immediately from the definition that this algebra is given by the pushout of the diagram

\[
\text{Free}(C) \amalg \text{Free}(D) \leftarrow \lim_{\eta \in \text{Bin}(\mathcal{O})} \text{Free}(C \otimes_{\eta} D) \rightarrow \text{Free}(E).
\]

Our main obstacle will be to describe the structure of this pushout more explicitly: in particular, we will show that \( \text{Free}(C) \otimes_{\alpha} \text{Free}(D) \) is roughly of the expected size (Remark 5.3.3.30). We begin by studying the data needed to make sense of the tensor product \( \text{Free}(C) \otimes_{\alpha} \text{Free}(D) \).

**Notation 5.3.3.8.** We define a category \( \mathcal{J} \) as follows:

- The objects of \( \mathcal{J} \) are triples \( (\langle n \rangle, S, T) \), where \( S \) and \( T \) are subsets of \( \langle n \rangle \) which contain the base point and \( \langle n \rangle = S \cup T \). In this case, we will abuse notation by regarding \( S \) and \( T \) as objects of \( \text{Fin}_n \).

- A morphism from \( (\langle n \rangle, S, T) \) to \( (\langle n' \rangle, S', T') \) in \( \mathcal{J} \) consists of a map \( \alpha : \langle n \rangle \to \langle n' \rangle \) in \( \text{Fin}_n \) which restricts to inert morphisms \( S \to S' \), \( T \to T' \).

We let \( \mathcal{O}^\circ \) denote the nerve of the category \( \mathcal{J} \). Note that the forgetful functor

\[
\mathcal{O}^\circ \to N(\text{Fin}_n)
\]

\( (\langle n \rangle, S, T) \mapsto \langle n \rangle \)

exhibits \( \mathcal{O}^\circ \) as an \( \infty \)-operad. The underlying \( \infty \)-category \( \mathcal{O} \) has exactly three objects

\[
\mathfrak{a}_- = ((1), (1), \{\ast\}) \quad \mathfrak{a}_+ = ((1), (1), (1)) \quad \mathfrak{a}_\pm = ((1), \{\ast\}, (1)).
\]

**Notation 5.3.3.9.** Let \( \mathcal{O}^\circ \) be an arbitrary \( \infty \)-operad. We let \( \mathcal{O}^{\mathcal{O}} \) denote the \( \infty \)-operad given by the fiber product \( \mathcal{O}^\circ \times_{N(\text{Fin}_n)} \mathcal{O}^\circ \). In the special case where the \( \infty \)-category \( \mathcal{O} \) is a contractible Kan complex, the forgetful functor

\[
\mathcal{O}(\mathcal{O}) \simeq \mathcal{O} \times \mathcal{O} \to \mathcal{O}
\]
is an equivalence of \( \infty \)-categories. In other words, \( \mathcal{O}(\mathcal{O}) \) is a Kan complex with exactly three connected components, each of which is contractible. In this case, we choose objects \( \mathfrak{a}_-, \mathfrak{a}_+, \mathfrak{a}_\pm \in \mathcal{O}(\mathcal{O}) \) lying over the corresponding objects of \( \mathcal{O} \). Note that we have a canonical homotopy equivalence

\[
\text{Mul}_{\mathcal{O}(\mathcal{O})}(\{\mathfrak{a}_-, \mathfrak{a}_+, \mathfrak{a}_\pm\}) \simeq \text{Bin}(\mathcal{O}),
\]

and there are no other non-identity operations in the \( \infty \)-operad \( \mathcal{O}(\mathcal{O})^\circ \).

**Example 5.3.3.10.** Let \( \mathcal{O}^\circ \) be an \( \infty \)-operad and let \( \mathcal{C}^\circ \) be a \( \mathcal{O} \)-monoidal \( \infty \)-category. Then composition with the forgetful functor \( \mathcal{O}(\mathcal{O})^\circ \to \mathcal{O}^\circ \) induces a map

\[
\theta : \text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{\mathcal{O}(\mathcal{O})/\mathcal{O}}(\mathcal{C}).
\]

When \( \mathcal{O} \) is a contractible Kan complex, we can think of this forgetful functor as taking a \( \mathcal{O} \)-algebra object \( A \in \text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C}) \) to its image in \( \mathcal{C} \) together with the family of multiplication maps \( \{A \otimes_{\eta} A \to A\}_{\eta \in \text{Bin}(\mathcal{O})} \) and all coherence data.
Let $\mathcal{O}$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex, let $\mathcal{C}$ be an $\mathcal{O}$-monoidal $\infty$-category and let $A \in \text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C})$. Then for each operation $\eta \in \text{Bin}(\mathcal{O})$, evaluation of $A$ on $\eta$ determines a map

$$A(\eta) : A(a_-) \otimes A(a_+) \to A(a_+).$$

As it turns out, this is all there is to say about $\mathcal{O}(\mathcal{O})$-algebra objects of $\mathcal{C}$:

**Proposition 5.3.3.11.** Let $\mathcal{O}$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex and let $\mathcal{C}$ be an $\mathcal{O}$-monoidal $\infty$-category. Then the construction outlined above determines an equivalence of $\infty$-categories

$$\text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C}) \to (\mathcal{C} \times \mathcal{C}) \times_{\text{Fun}(\text{Bin}(\mathcal{O}) \times \{0\}, \mathcal{C})} \text{Fun}(\text{Bin}(\mathcal{O}) \times \Delta^1, \mathcal{C}) \times_{\text{Fun}(\text{Bin}(\mathcal{O}) \times \{1\}, \mathcal{C})} \mathcal{C},$$

**Corollary 5.3.3.12.** Let $\mathcal{O}$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex, let $\mathcal{C}$ be an $\mathcal{O}$-monoidal $\infty$-category, and let $A, B \in \text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C})$. Then the diagram of spaces

$$\begin{align*}
\text{Map}_{\text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C})}(A, B) &\to \text{Map}_\mathcal{C}(A(a_-), B(a_-) \times \text{Map}_\mathcal{C}(A(a_+), B(a_+))) \\
\text{Map}_\mathcal{C}(A(a_\pm), B(a_\pm)) &\to \lim_{\eta \in \text{Bin}(\mathcal{O})} \text{Map}_\mathcal{C}(A(a_-) \otimes \eta A(a_+), B(a_\pm))
\end{align*}$$

is a homotopy pullback square.

**Corollary 5.3.3.13.** Let $\mathcal{O}$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex, let $\mathcal{C}$ be an $\mathcal{O}$-monoidal $\infty$-category, let $A \in \text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C})$, and let $B \in \text{Alg}_\mathcal{O}(\mathcal{C})$. Then the diagram of spaces

$$\begin{align*}
\text{Map}_{\text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C})}(A, B) &\to \text{Map}_\mathcal{C}(A(a_-), B(a_-) \times \text{Map}_\mathcal{C}(A(a_+), B)) \\
\text{Map}_\mathcal{C}(A(a_\pm), B) &\to \lim_{\eta \in \text{Bin}(\mathcal{O})} \text{Map}_\mathcal{C}(A(a_-) \otimes \eta A(a_+), B)
\end{align*}$$

is a homotopy pullback square.

**Corollary 5.3.3.14.** Let $\mathcal{O}$ be an $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex and let $\mathcal{C}$ be an $\mathcal{O}$-monoidal $\infty$-category. Assume that the $\infty$-category $\mathcal{C}$ admits small colimits and that the $\mathcal{O}$-monoidal structure on $\mathcal{C}$ is compatible with small colimits. Let

$$\text{Free} : \mathcal{C} \to \text{Alg}_\mathcal{O}(\mathcal{C}) \quad \rho : \text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_\mathcal{O}(\mathcal{C})$$

denote the left adjoints to the forgetful functors. Then for any object $A \in \text{Alg}_{\mathcal{O}(\mathcal{O})/\mathcal{E}_k}(\mathcal{C})$, there is a canonical pushout diagram

$$\begin{align*}
\text{Map}_\mathcal{C}(A(a_-), B(a_-) \times \rho A(a_+)) &\to \lim_{\eta \in \text{Bin}(\mathcal{O})} \text{Free}(A(a_-) \otimes \eta A(a_+)) \\
\text{Free}(A(a_-) \amalg \rho A(a_+)) &\to \rho(A).
\end{align*}$$

**Proof of Proposition 5.3.3.11.** Let $f$ denote the unique morphism from $((2), \{0, *\}, \{1, *\})$ to $((1), (1), (1))$ in $\mathcal{O}$, so that $f$ determines a monomorphism of simplicial sets $\Delta^1 \to \mathcal{O}$. We let $\mathcal{M}$ denote the inverse image $\mathcal{O}(\mathcal{O}) \times_{\mathcal{O}} \Delta^1$, which we will identify with a subcategory of $\mathcal{O}(\mathcal{O})$. Then the projection $p : \mathcal{M} \to \Delta^1$ exhibits $\mathcal{M}$ as a correspondence from $\mathcal{M}_0 \simeq \mathcal{O}_{(2)}$ to $\mathcal{M}_1 \simeq \mathcal{O}_{(1)}$. Let us identify $\text{Bin}(\mathcal{O})$ with the space $\text{Fun}_{\Delta^1}(\Delta^1, \mathcal{M})$ of sections of $p$. According to Proposition B.3.17, the canonical map

$$\mathcal{O}_{(2)} \times \text{Bin}(\mathcal{O}) \times \{0\} \times \text{Bin}(\mathcal{O}) \times \Delta^1 \times \mathcal{O}_{(1)} \to \mathcal{M}$$
is a categorical equivalence of simplicial sets. Since the $\infty$-categories $\mathcal{O}^{\otimes}_{(2)}$ and $\mathcal{O}^{\otimes}_{(1)}$ are contractible Kan complexes, we obtain an equivalence of $\infty$-categories

$$\text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{M}, \mathcal{C}^{\otimes}) \simeq (\mathcal{C} \times \mathcal{C}) \times_{\text{Fun}(\mathcal{O}(\mathcal{C}) \times \{0\}, \mathcal{C})} \text{Fun}(\mathcal{O}(\mathcal{C}) \times \Delta^1, \mathcal{C}) \times_{\text{Fun}(\mathcal{O}(\mathcal{C}) \times \{1\}, \mathcal{C})} \mathcal{C}.$$ 

We will complete the proof by showing that the restriction map

$$\theta : \text{Alg}_{\mathcal{O}^{\otimes}}(\mathcal{C}) \to \text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{M}, \mathcal{C}^{\otimes})$$

is a trivial Kan fibration of simplicial sets.

We begin by introducing a slight enlargement of the correspondence $\mathcal{M}$. Consider the unique maps

$$f_- : (\langle 2 \rangle, \{0, *\}, \{1, *\}) \to (\langle 1 \rangle, \{1\}, \{1\}), \quad f_+ : (\langle 2 \rangle, \{0, *\}, \{1, *\}) \to (\langle 1 \rangle, \{1\}, \langle 1 \rangle)$$

in the $\infty$-category $\mathcal{O}^{\otimes}$. We will abuse notation by identifying $\mathcal{M}$. It now follows from Proposition T.4.3.2.15 that the restriction map

$$\theta' : \mathcal{O}^{\otimes} \to \mathcal{D}$$

is a categorical equivalence of simplicial sets. Since the underlying Kan complex of $\mathcal{M}^\prime$ has exactly four connected components, each of which is contractible: the components containing the objects $a_-, a_+, a_\pm \in \mathcal{O}$ together with another component corresponding to the object

$$(a_-, a_+) \in \mathcal{O} \times \mathcal{O} \simeq (\mathcal{O}^{\otimes}_{(2)}).$$

Let $q : \mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes}$ be the map which exhibits $\mathcal{C}^{\otimes}$ as a $\mathcal{O}$-monoidal $\infty$-category and let $\mathcal{D} \subseteq \text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{M}^\prime, \mathcal{C}^{\otimes})$ denote the full subcategory spanned by those functors $A : \mathcal{M}^\prime \to \mathcal{C}^{\otimes}$ for which the induced maps

$$A(a_-) \hookrightarrow A(a_-, a_+) \to A(a_+)$$

are inert morphisms of $\mathcal{C}^{\otimes}$. Then the forgetful functor $\theta'$ factors as a composition

$$\text{Alg}_{\mathcal{O}^{\otimes}}(\mathcal{C}) \xrightarrow{\theta} \mathcal{D} \xrightarrow{\theta'} \text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{M}, \mathcal{C}^{\otimes}).$$

Note that an object $A \in \text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{M}^\prime, \mathcal{C}^{\otimes})$ belongs to $\mathcal{D}$ if and only if $A$ is a $q$-left Kan extension of $q|_\mathcal{M}$. It follows from Proposition T.4.3.2.15 that the map $\theta'$ is a trivial Kan fibration. We will complete the proof by showing that $\theta'$ is also a trivial Kan fibration. Let $A$ be an object of $\text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{M}^\prime, \mathcal{C}^{\otimes})$. Fix an object $Q \in \mathcal{O}^{\otimes}$ having image $(\langle n \rangle, S, T)$ in $\mathcal{O}^{\otimes}$. For $1 \leq i \leq n$, the inert morphism $\rho^i : \langle n \rangle \to \langle 1 \rangle$ of Notation 2.0.0.2 can be lifted (in an essentially unique fashion) to an inert morphism

$$Q \to \begin{cases} a_- & \text{if } i \in S, i \notin T \\ a_- & \text{if } i \in T, i \notin S \\ a_\pm & \text{if } i \in S \cap T \end{cases}$$

in $\mathcal{O}^{\otimes}$ which we will denote by $\overline{\rho}_i$. Let $\mathcal{E}$ denote the full subcategory of $\mathcal{M}^\prime_\mathcal{Q}/ = \mathcal{M}^\prime \times_{\mathcal{O}^{\otimes}} \mathcal{O}(\mathcal{O})^{\otimes}/$ spanned by the inert morphisms $Q \to M$. It is not difficult to see that the inclusion $\mathcal{E} \hookrightarrow \mathcal{M}^\prime_\mathcal{Q}/$ admits a right adjoint and is therefore right cofinal. Moreover, if $A|_{\mathcal{M}} \in \mathcal{D}$, then the restriction of $A$ to $\mathcal{M}^\prime_\mathcal{Q}/$ is a $q$-right Kan extension of its restriction to the finite set $\{\overline{\rho}_i\}_{1 \leq i \leq n} \subseteq \mathcal{M}^\prime_\mathcal{Q}/$. This proves the following:

(\ast) If $A \in \text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{O}^{\otimes}, \mathcal{C}^{\otimes})$ satisfies $A|_{\mathcal{M}} \in \mathcal{D}$, then $A$ is a $q$-right Kan extension of $A|_{\mathcal{M}^\prime}$ at an object $Q \in \mathcal{O}^{\otimes}$ if and only if $A(\overline{\rho}_i)$ is an inert morphism in $\mathcal{C}^{\otimes}$ for each $i$, where the morphisms $\overline{\rho}_i$ are defined as above.

By virtue of Remark 2.1.2.9, the condition described in (\ast) is satisfied for all objects $Q \in \mathcal{O}^{\otimes}$ if and only if $A$ is a $\mathcal{O}(\mathcal{O})$-algebra object of $\mathcal{C}$. It now follows from Proposition T.4.3.2.15 that the restriction map $\theta'$ is a trivial Kan fibration, as desired.
We now introduce a slight variant of Notation 5.3.3.8 which will be useful in what follows.

**Construction 5.3.3.15.** Consider the horn $\Lambda^2_2 \subseteq \Delta^2$, isomorphic to the pushout $\Delta^1 \amalg \{1\} \Delta^1$. There is an evident map $Q^\otimes \to \text{Fun}(\Lambda^2_2, N(\text{Fin}_*) )$, which carries an object $((n), S, T)$ in $Q^\otimes$ to the diagram

\[
\begin{array}{c}
 T \\
 \downarrow \\
 S \rightarrow (n);
\end{array}
\]

here we abuse notation by identifying the finite pointed sets $S$ and $T$ with objects of $\text{Fin}_*$.

Let $\mathcal{O}$ be an $\infty$-operad. We let $\mathcal{O}(\Lambda^2_2)_{\otimes}$ denote the fiber product

\[ \text{Fun}(\Lambda^2_2, \mathcal{O})_{\otimes} \times_{\text{Fun}(\Lambda^2_2, N(\text{Fin}_*) \otimes \mathcal{O})_{\otimes}} \mathcal{O}_{\otimes}. \]

Evaluation at the vertex $\{2\} \subseteq \Lambda^2_2$ induces a forgetful functor $\mathcal{O}(\Lambda^2_2)_{\otimes} \to \mathcal{O}_{\otimes}$. If $\mathcal{O}_{\otimes}$ is a unital $\infty$-operad and $\mathcal{O}$ is a Kan complex, then the forgetful functor $\mathcal{O}(\Lambda^2_2)_{\otimes} \to \mathcal{O}_{\otimes}$ is a trivial Kan fibration.

**Remark 5.3.3.16.** Let $q : \mathcal{O}_{\otimes} \to N(\text{Fin}_*)$ be an $\infty$-operad. We can identify the objects of $\mathcal{O}(\Lambda^2_2)_{\otimes}$ with diagrams

\[ X_S \to X \leftarrow X_T \]

for which the induced maps $q(X_S) \to q(X) \leftarrow q(X_T)$ are injections of finite pointed sets. The forgetful functor $\mathcal{O}(\Lambda^2_2)_{\otimes} \to \mathcal{O}_{\otimes}$ is given on objects by

\[ (X_S \to X \leftarrow X_T) \mapsto (q(X), \text{im}(q(X_S) \to q(X)), \text{im}(q(X_T) \to q(X))). \]

**Notation 5.3.3.17.** Let $\mathcal{O}_{\otimes}$ be a unital $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex. We let $\text{Triv}(\mathcal{O})_{\otimes}$ denote the subcategory of $\mathcal{O}_{\otimes}$ spanned by the inert morphisms. Note that our assumption on $\mathcal{O}$ guarantees that the projection map $\text{Triv}(\mathcal{O})_{\otimes} \to \text{Triv}_{\otimes}$ is an equivalence of $\infty$-operads.

Let $\text{Env}_\mathcal{O}(\text{Triv}(\mathcal{O}))_{\otimes}$ denote the $\mathcal{O}$-monoidal envelope of the $\infty$-operad $\text{Triv}(\mathcal{O})_{\otimes}$ (see Construction 2.2.4.1): more concretely, $\text{Env}_\mathcal{O}(\text{Triv}(\mathcal{O}))_{\otimes}$ is the full subcategory of the fiber product

\[ \text{Triv}(\mathcal{O})_{\otimes} \times_{\text{Fun}(\{0\}, \mathcal{O}_{\otimes})} \text{Fun}(\Delta^1, \mathcal{O}_{\otimes}) \]

spanned by the active morphisms in $\mathcal{O}_{\otimes}$.

We have maps of $\infty$-operads

\[ \iota_-, \iota_+ : \mathcal{O}(\Lambda^2_2)_{\otimes} \to \text{Env}_\mathcal{O}(\text{Triv}(\mathcal{O}))_{\otimes}, \]

given on objects by the formulae

\[ \iota_-(X_S \to X \leftarrow X_T) = (X_S \to X) \]

\[ \iota_+(X_S \to X \leftarrow X_T) = (X_T \to X). \]

If $\mathcal{C}$ is an $\mathcal{O}$-monoidal $\infty$-category, then composition with the functors $\iota_-$ and $\iota_+$ determines forgetful functors

\[ \psi_-, \psi_+ : \mathcal{C} \cong \text{Alg}_{\text{Triv}(\mathcal{O})/\mathcal{O}}(\mathcal{C}) \cong \text{Fun}_{\mathcal{O}}(\text{Env}_\mathcal{O}(\text{Triv}(\mathcal{O})), \mathcal{C}) \to \text{Alg}_{\mathcal{O}(\Lambda^2_2)_{\otimes}/\mathcal{O}}(\mathcal{C}) \cong \text{Alg}_{\mathcal{O}/\mathcal{O}}(\mathcal{C}) \]

More concretely, we have

\[ (\psi_- C)(a_-) = C \quad (\psi_- C)(a_+) = 1 \quad (\psi_- C)(a_{\pm}) = C \]

\[ (\psi_+ C)(a_-) = 1 \quad (\psi_+ C)(a_+) = C \quad (\psi_+ C)(a_{\pm}) = C \]

where in both cases, the collection of maps $\{C \otimes_{\eta} 1 \to C\}_{\eta \in \text{Bin}(\mathcal{O})}$ is determined by the role of $1$ as the unit object of $\mathcal{C}$.
5.3. CENTERS AND CENTRALIZERS

Remark 5.3.3.18. In the situation of Notation 5.3.3.17, let Env_{\mathcal{O}}^\otimes be the \mathcal{O}-monoidal envelope of \mathcal{O} itself: that is, the full subcategory of \text{Fun}(\Delta^1, \mathcal{O}^\otimes) spanned by the active morphisms). Composing the forgetful functor \overline{\mathcal{O}(\mathcal{O})^\otimes} \to \mathcal{O}^\otimes with the diagonal inclusion \mathcal{O}^\otimes \to \mathcal{U}_\mathcal{O}(\mathcal{O})^\otimes, we obtain a morphism of \infty-operads \delta : \overline{\mathcal{O}(\mathcal{O})} \to \mathcal{U}_\mathcal{O}(\mathcal{O})^\otimes. We will identify \mathcal{U}_\mathcal{O}(\text{Triv}(\mathcal{O}))^\otimes with an \mathcal{O}-monoidal subcategory of \mathcal{U}_\mathcal{O}(\mathcal{O})^\otimes, so that the functors \iota_- and \iota_+ of Notation 5.3.3.17 can be regarded as morphisms of \infty-operads from \overline{\mathcal{O}(\mathcal{O})}^\otimes to \mathcal{U}_\mathcal{O}(\mathcal{P})^\otimes. There are evident natural transformations

\iota_- \to \delta \leftarrow \iota_+,

which carry an object \(X_S \rightarrow X \leftarrow X_T\) in \(\overline{\mathcal{O}(\mathcal{O})}^\otimes\) to the maps

\(\alpha \to \text{id}_X \leftarrow \beta\)

in \(\mathcal{U}_\mathcal{O}(\mathcal{O})^\otimes\).

If \(\mathcal{C}\) is an \(\mathcal{O}\)-monoidal \infty-category and \(A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})\), we obtain natural maps of \(\mathcal{O}\)-algebras

\(\psi_- (A) \to A|_{\mathcal{O}^\otimes} \leftarrow \psi_+ (A)\).

For example, the map \(\psi_- (A) \to A|_{\mathcal{O}^\otimes}\) is given by the identity map from \(A\) to itself when evaluated on the objects \(a_-\) an \(a_+\), and by the unit map of \(A\) when evaluated on \(a_+\).

The main ingredient in our proof of Theorem 5.3.3.3 is the following:

**Proposition 5.3.3.19.** Let \(\mathcal{C}\) be a symmetric monoidal \infty-category. Assume that \(\mathcal{C}\) admits small colimits and that the tensor product \(\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}\) preserves small colimits separately in each variable. Let \(\mathcal{O}^\otimes\) be a coherent operad for which \(\mathcal{O}\) is a contractible Kan complex. Let \(A\) and \(B\) be \(\mathcal{O}\)-algebra objects of \(\mathcal{C}\), let \(C\) and \(D\) be objects of \(\mathcal{C}\), and suppose we are given morphisms

\(\alpha : C \to A \quad \beta : D \to B\)

in the \(\infty\)-category \(\mathcal{C}\). Assume that \(\alpha\) exhibits \(A\) as the free \(\mathcal{O}\)-algebra generated by \(C\) and that \(\beta\) exhibits \(B\) as the free \(\mathcal{O}\)-algebra generated by \(D\). Then the induced map

\(\psi_- (C) \otimes \psi_+ (D) \to \psi_- (A) \otimes \psi_+ (B) \to (A \otimes B)|_{\mathcal{O}^\otimes}\)

exhibits \(A \otimes B\) as the free \(\mathcal{O}\)-algebra generated by the \(\mathcal{O}(\mathcal{O})\)-algebra \(\psi_- (C) \otimes \psi_+ (D) \in \text{Alg}_{\mathcal{O}(\mathcal{O})}(\mathcal{C})\).

**Remark 5.3.3.20.** In the statement of Proposition 5.3.3.19, the hypothesis that \(\mathcal{C}\) is symmetric monoidal can be weakened: it is only important that there is a reasonable tensor product on \(\mathcal{O}\)-algebra objects of \(\mathcal{C}\). For example, if \(\mathcal{O}^\otimes = \mathbb{E}_k^\otimes\), then it is sufficient to assume that \(\mathcal{C}\) is an \(\mathbb{E}_{k+1}\)-monoidal \infty-category.

**Proof of Theorem 5.3.3.3.** Combine Proposition 5.3.3.19 with Corollary 5.3.3.14. \(\square\)

We now turn to the proof of Proposition 5.3.3.19. Fix an object \(Z \in \mathcal{O}\). Note that the maps \(\iota_-\) and \(\iota_+\) of Notation 5.3.3.17 induce functors

\(\rho_- : \mathcal{O}^\otimes \times_{\mathcal{O}^\otimes} (\mathcal{O}^\otimes)^{\text{act}}_{/Z} \to \text{Triv}(\mathcal{O})^\otimes \times_{\mathcal{O}^\otimes} (\mathcal{O}^\otimes)^{\text{act}}_{/Z}\).

The main ingredient in our proof is the following fundamental calculation:

**Lemma 5.3.3.21.** Assume that the \(\infty\)-operad \(\mathcal{O}^\otimes\) is coherent and that \(\mathcal{O}\) is a Kan complex. For each object \(Z \in \mathcal{O}\), the maps \(\rho_-\) and \(\rho_+\) determine a weak homotopy equivalence of simplicial sets

\(\mathcal{O}(\mathcal{O})^\otimes \times_{\mathcal{O}^\otimes} (\mathcal{O}^\otimes)^{\text{act}}_{/Z} \to (\text{Triv}(\mathcal{O})^\otimes \times_{\mathcal{O}^\otimes} (\mathcal{O}^\otimes)^{\text{act}}_{/Z})^2\).
Proof of Proposition 5.3.3.19. Let \( q : \mathcal{C}^\otimes \to \mathcal{N}(\mathcal{O}_{\mathcal{F}}) \) exhibit \( \mathcal{C} \) as a symmetric monoidal \( \infty \)-category. Fix a point \( Z \in \mathcal{O} \) and let \( K \) denote the \( \infty \)-category \( \mathcal{Q}(\mathcal{O})^\otimes \otimes (\mathcal{O})^\otimes /Z \). Then the map of \( \mathcal{Q}(\mathcal{O}) \)-algebras \( f : (\psi)_C \otimes (\psi)_D \to (A \otimes B)/\mathcal{O} \) determines a map \( \lambda : K^\circ \to \mathcal{C}^\otimes \) which carries the cone point to \( A(Z) \otimes B(Z) \in \mathcal{C} \) and is given on \( K \) by the tensor product of \( (\psi)_C \) with \( (\psi)_D \). We wish to show that \( \lambda \) is an operadic \( q \)-colimit diagram. Using Propositions 3.1.1.15 and 3.1.1.16 (together with our assumption that the tensor product on \( \mathcal{C} \) is compatible with countable colimits), we are reduced to proving that a certain map \( \lambda' : K^\circ \to \mathcal{C} \) is a colimit diagram.

Let \( L = \mathcal{F}(\mathcal{O})^\otimes \otimes (\mathcal{O})^\otimes /Z \). Using the factorization of \( f \) as a tensor product, we see that \( \lambda' \) is homotopic to the composite map

\[
K^\circ (\rho_-\rho_+) \to (L \times L)^\circ \to L^\circ \times \mathcal{L}^\circ \times \mathcal{L}^\circ \to \mathcal{C} \times \mathcal{C} \to \mathcal{C}.
\]

Here \( \mathcal{L} \) and \( \mathcal{L}' \) are maps determined by the maps \( C \to A \) and \( D \to B \), and are therefore colimit diagrams by virtue of our assumption that these maps exhibit \( A \) and \( B \) are the free \( \mathcal{O} \)-algebras generated by \( C \) and \( D \) respectively. Since the tensor product on \( \mathcal{C} \) preserves small colimits separately in each variable, we conclude that the composite map

\[
(L \times L)^\circ \to L^\circ \times \mathcal{L}^\circ \times \mathcal{L}^\circ \to \mathcal{C} \times \mathcal{C} \to \mathcal{C}
\]

is a colimit diagram. To complete the proof, it will suffice to show that the map \( (\rho_-\rho_+) : K \to L \times L \) is left cofinal. Since \( L \) is a Kan complex, this is equivalent to the assertion that \( (\rho_-\rho_+) \) is a weak homotopy equivalence (Corollary T.4.1.2.6), which follows from Lemma 5.3.3.21. \( \square \)

Proof of Lemma 5.3.3.21. Let \( q : \mathcal{O}^\otimes \to \mathcal{N}(\mathcal{O}_{\mathcal{F}}) \) exhibit \( \mathcal{O}^\otimes \) as an \( \infty \)-operad and let \( K \) and \( L \) be as in the proof of Proposition 5.3.3.19; we wish to show that the map \( (\rho_-\rho_+) : K \to L \times L \) is a weak homotopy equivalence. Since \( L \) is a Kan complex, it will suffice to show that each homotopy fiber of \( (\rho_-\rho_+) \) is weakly contractible. Fix a point of \( L \times L \), corresponding to a pair of active morphisms \( X_- \xrightarrow{\alpha} Z \xleftarrow{\beta} X_+ \) in the \( \infty \)-category \( \mathcal{O}^\otimes \). Unwinding the definitions, we see that the homotopy fiber product \( K \times_{L \times L} \{ (\alpha, \beta) \} \) can be identified with the full subcategory

\[
\mathcal{E} \subseteq \mathcal{O}^\otimes_{X_-/\mathcal{O}^\otimes_{X_+}}^\otimes \mathcal{O}^\otimes_{X_+/\mathcal{O}^\otimes_{X_+}}^\otimes
\]

spanned by those diagrams

\[
X_- \xrightarrow{\alpha} Y \xrightarrow{\beta} Z \xleftarrow{\alpha, \beta} X_+
\]

for which the underlying maps \( q(X_-) \to q(Y) \to q(X_+) \) are injective and the map \( q(X_-) \amalg q(X_+) \to q(Y) \) is surjective. Let \( \mathcal{E}^+ \) denote the full subcategory of \( \mathcal{O}^\otimes_{X_-/\mathcal{O}^\otimes_{X_+}}^\otimes \mathcal{O}^\otimes_{X_+/\mathcal{O}^\otimes_{X_+}}^\otimes \) spanned by those diagrams where \( \alpha \) and \( \beta \) are injective. Using the assumption that the \( \infty \)-operad \( \mathcal{O}^\otimes \) is unital, we see that the inclusion \( \mathcal{E} \to \mathcal{E}^+ \) admits a right adjoint and is therefore a weak homotopy equivalence. We will complete the proof by showing that \( \mathcal{E}^+ \) is weakly contractible.

We will henceforth write \( \mathcal{E}^+(X_+) \) instead of \( \mathcal{E}^+ \) to indicate the dependence of \( \mathcal{E}^+ \) on the object \( X_+ \) (which we will allow to vary). If \( m = 0 \), then the \( \infty \)-category \( \mathcal{E}^+(X_+) \) admits an initial object (given by \( X_- \)) and there is nothing to prove. Otherwise, we can choose a semi-inert morphism \( \alpha : X_+ \to X_+ \) where \( q(\alpha) \simeq (m-1) \). Let \( \mathcal{K}_0 \) be as in Notation 3.3.2.1 and let \( \mathcal{X} \) denote the fiber product

\[
(\mathcal{K}_0)_{\text{id}_X} \times (\mathcal{K}_0)_{/\text{id}_X} \xrightarrow{(\mathcal{K}_0)_{/\text{id}_X}}\}.
\]
5.3. CENTERS AND CENTRALIZERS

so that evaluation at 0 and 1 induce maps

\[ e_0 : X \to O_{X_-/\mathbb{Z}} \times_{O_{\mathbb{Z}}} O_{X_+/\mathbb{Z}} \]

\[ e_1 : X \to O_{X_-/\mathbb{Z}} \times_{O_{\mathbb{Z}}} O_{X_+/\mathbb{Z}} \]

and let \( X_0 \) be the inverse image of \( \mathcal{E}^+(X_+) \) under the map \( e_1 \). Let \( e_0^{-1}(\mathcal{E}^+(X_+)) \) and \( e_1^{-1}(\mathcal{E}^+(X_+)) \) denote the inverse images of \( \mathcal{E}^+(X_+) \) and \( \mathcal{E}^+(X_+) \) under the functors \( e_0 \) and \( e_1 \), respectively, so that we have a commutative diagram

\[ \mathcal{E}^+(X_+) \leftarrow e_0^{-1}(\mathcal{E}^+(X_+)) \supseteq e_1^{-1}(\mathcal{E}^+(X_+)) \to \mathcal{E}^+(X_+). \]

Since \( O^\otimes \) is coherent, evaluation at 0 induces a flat categorical fibration \( X_0 \to O^\otimes \) (Theorem 3.3.2.2) so that the map \( e_0^{-1}(\mathcal{E}^+(X_+)) \to \mathcal{E}^+(X_+) \) is a weak homotopy equivalence by virtue of Lemma 3.3.2.8 (see Example 3.3.2.9). The inclusion \( e_1^{-1}(\mathcal{E}^+(X_+)) \subseteq e_0^{-1}(\mathcal{E}^+(X_+)) \) and the projection maps \( e_1^{-1}(\mathcal{E}^+(X_+)) \to \mathcal{E}^+(X_+) \) admit right adjoints and are therefore weak homotopy equivalences. Since the \( \infty \)-category \( \mathcal{E}^+(X_+) \) is weakly contractible by the inductive hypothesis, it follows that \( \mathcal{E}^+(X_+) \) is weakly contractible as desired.

We now describe another application of Lemma 5.3.3.21.

**Definition 5.3.3.22.** Let \( O^\otimes \) be an \( \infty \)-operad for which \( O \) is a contractible Kan complex and let \( \mathcal{C} \) be a \( O \)-monoidal \( \infty \)-category. A **commutativity datum** is an object \( M \in \text{Alg}_{\mathcal{O}^\otimes/O}(\mathcal{C}) \) with the following property: for every point \( \eta \in \text{Bin}(O) \), the induced map

\[ M(\eta) : M(a_-) \otimes_{\eta} M(a_+) \to M(a_+) \]

is an equivalence in \( \mathcal{C} \).

**Example 5.3.3.23.** If \( O^\otimes = \mathbb{E}_0^\otimes \), then the space of binary operations \( \text{Bin}(O) \) is empty and therefore every \( \mathcal{Q}(O) \)-algebra is a commutativity datum.

**Example 5.3.3.24.** In the situation of Definition 5.3.3.22, for every object \( C \in \mathcal{C} \) the \( \mathcal{Q}(O) \)-algebras \( \psi_-(C) \) and \( \psi_+(C) \) of Notation 5.3.3.17 are commutativity data in \( \mathcal{C} \).

**Remark 5.3.3.25.** In the situation of Definition 5.3.3.22, suppose that we fix a base point \( \eta_0 \in \text{Bin}(O) \). Using Proposition 5.3.3.11, we see that a commutativity datum \( M \) amounts to the following:

(a) A pair of objects \( C = M(a_-), D = M(a_+) \in \mathcal{C} \).

(b) A family of equivalences \( \{ \alpha_\eta : C \otimes_{\eta} D \to C \otimes_{\eta_0} D \}_{\eta \in \text{Bin}(O)} \) for which \( \alpha_{\eta_0} \) is the identity map (here \( \alpha_\eta \) is given by the composition \( M(\eta_0)^{-1} \circ M(\eta) \)).

In the special case where the monoidal structure on \( \mathcal{C} \) is symmetric, the family of objects \( \{ C \otimes_{\eta} D \}_{\eta \in \text{Bin}(O)} \) is constant. We can therefore replace (b) by the following data:

(b') A map of pointed spaces \( \alpha : \text{Bin}(O) \to \text{Map}_{\mathcal{C}^\otimes}(C \otimes D, C \otimes D) \).

**Example 5.3.3.26.** If \( O^\otimes = \text{Comm} \), then a commutativity datum in a \( \mathcal{O} \)-monoidal \( \infty \)-category \( \mathcal{C} \) is determined by a pair of objects \( C, D \in \mathcal{C} \).

**Example 5.3.3.27.** If \( O^\otimes = \text{Ass}^\otimes \), then a commutativity datum in a \( \mathcal{O} \)-monoidal \( \infty \)-category \( \mathcal{C} \) is given by a pair of objects \( C, D \in \mathcal{C} \) together with an equivalence \( \alpha : D \otimes C \to C \otimes D \).

**Example 5.3.3.28.** Let \( O^\otimes \) be as in Definition 5.3.3.22 and let \( \mathcal{C} \) be a \( \mathcal{O} \)-monoidal \( \infty \)-category. For every pair of objects \( (C, D) \in \mathcal{C} \), the construction \( \eta \mapsto C \otimes_{\eta} D \) determines a map of Kan complexes \( \beta : \text{Bin}(O) \to \mathcal{C}^\otimes \) which is nullhomotopic if and only if \( (C, D) \) can be extended to a commutativity datum in \( \mathcal{C} \).
Assume now that $\mathcal{O}^\otimes = \mathcal{E}^\otimes_k$ for $2 \leq k < \infty$ and choose a point $\eta_0$ in $\text{Bin}(\mathcal{O}) \simeq S^{k-1}$. Then we can identify $\beta$ with a pointed map from $S^{k-2}$ to the loop space

$$\Omega \mathcal{E}^\otimes \simeq \text{Map}_{\mathcal{E}^\otimes}(C \otimes_{\eta_0} D, C \otimes_{\eta_0} D).$$

We therefore have an obstruction

$$[\beta] \in \pi_{k-2} \text{Map}_{\mathcal{E}^\otimes}(C \otimes_{\eta_0} D, C \otimes_{\eta_0} D)$$

which vanishes if and only if $(C, D)$ can be extended to a commutativity datum in $\mathcal{E}$.

**Example 5.3.3.29.** In the situation of Example 5.3.3.28, suppose that the monoidal structure on $\mathcal{O}$ is symmetric and that $\mathcal{O}^\otimes = \mathcal{E}^\otimes_k$ for $1 \leq k < \infty$. Fix a point $\eta \in \text{Bin}(\mathcal{O}) \simeq S^{k-1}$. Then the collection of commutativity data with underlying objects $C, D \in \text{Bin} \mathcal{E}$ are classified by the set $\pi_{k-1} \text{Map}_{\mathcal{E}^\otimes}(C \otimes D, C \otimes D)$.

**Proposition 5.3.3.30.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad for which $\mathcal{O}$ is a contractible Kan complex and let $\mathcal{E}^\otimes$ be a $\mathcal{O}$-monoidal $\infty$-category which admits small colimits which are compatible with the $\mathcal{O}$-monoidal structure on $\mathcal{E}$. Let $M$ be a commutativity datum in $\mathcal{E}$ and let $A$ be the free $\mathcal{O}$-algebra object generated by $M$. Let $\text{Free}: \mathcal{E} \to \text{Alg}_/\mathcal{O}(\mathcal{E})$ denote a left adjoint to the forgetful functor. Then, for every point $\eta \in \text{Bin}(\mathcal{O})$, the induced map

$$\psi: \text{Free}(M(a_-)) \otimes_{\eta} \text{Free}(M(a_+)) \to A \otimes_{\eta} A$$

in the $\infty$-category $\mathcal{E}$.

**Proof.** Let $K$ and $L$ be as in the proof of Proposition 5.3.3.19, so that $A$ can be identified (as an object of $\mathcal{E}$) with the colimit of a certain diagram $\phi: K \to C$ determined by $M$. Since $\mathcal{O}^\otimes$ is coherent, Lemma 5.3.3.21 asserts that the map $(\rho_-, \rho_+) : K \to L \times L$ is a weak homotopy equivalence. The choice of $\eta$ determines a map $L \times L \to K$ which is a section of $(\rho_-, \rho_+) : K \to L \times L$, and $\psi$ can be identified with the canonical map $\lim_\psi(\phi \circ s) \to \lim_\psi(\phi)$. Our hypothesis that each of the maps $M(\eta)$ is an equivalence guarantees that $\phi$ carries each morphism in $K$ to an equivalence in $\mathcal{E}$. Since $(\rho_-, \rho_+)$ is a weak homotopy equivalence, it follows that $\phi$ factors (up to homotopy) as a composition

$$K \xrightarrow{(\rho_-, \rho_+)} L \times L \xrightarrow{\phi'} \mathcal{E}.$$

Consequently, the map $\psi$ fits into a commutative diagram

$$\begin{array}{ccc}
\lim_\psi(\phi' \circ (\rho_-, \rho_+)) & \xrightarrow{\psi} & \lim_\psi(\phi') \\
\downarrow \lim_\psi(\phi' \circ (\rho_- \circ s)) & & \\
\lim_\psi(\phi' \circ (\rho_-, \rho_+)) & \xrightarrow{\psi} & \lim_\psi(\phi').
\end{array}$$

We conclude by observing that the bottom vertical map is an equivalence because $(\rho_-, \rho_+) \circ s$ is homotopic to the identity map from $L \times L$ to itself, and that the the right diagonal map is an equivalence by virtue of the fact that $(\rho_-, \rho_+)$ is left cofinal (Lemma 5.3.3.21 and Corollary T.4.1.2.6). \qed

**Warning 5.3.3.31.** Let $\mathcal{O}^\otimes$ be as in Proposition 5.3.3.30 and let $\mathcal{E}$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{E}$ admits small colimits and that the tensor product $\otimes: \mathcal{E} \times \mathcal{E} \to \mathcal{E}$ preserves small colimits separately in each variable. Let $M = (C, D, \alpha)$ be a commutativity datum in $\mathcal{E}$ and let $A$ denote the free $\mathcal{O}$-algebra generated by $M$. Then each point $\eta \in \text{Bin}(\mathcal{O})$ determines an equivalence $\psi_\eta : \text{Free}(C) \otimes \text{Free}(D) \to A$. However:

(a) The map $\psi_\eta$ is a morphism in the $\infty$-category $\mathcal{E}$: it is generally not a map of $\mathcal{O}$-algebras, even though both $\text{Free}(C) \otimes \text{Free}(D)$ and $A$ can be regarded as $\mathcal{O}$-algebras.
(b) The map \( \psi_\eta \) depends on the chosen point \( \eta \in \text{Bin}(\mathcal{O}) \), even though the domain and codomain of \( \psi_\eta \) do not.

(c) The objects \( \text{Free}(C) \otimes \text{Free}(D) \) and \( A \) need not be equivalent if the space \( \text{Bin}(\mathcal{O}) \) is empty. For example, if \( \mathcal{O}^\otimes = \mathbb{E}_0^\otimes \), then every triple of objects \( M = (M_-, M_+, M_\pm) \) can be regarded as a commutativity datum in \( \mathcal{C} \). The free \( \mathcal{O} \)-algebra generated by \( M \) is given by the coproduct

\[
1 \amalg M_- \amalg M_+ \amalg M_\pm,
\]

while the tensor product \( \text{Free}(M_-) \otimes \text{Free}(M_+) \) is given by

\[
1 \amalg M_- \amalg M_+ \amalg (M_- \otimes M_+).
\]

In the situation of Proposition 5.3.3.30, suppose we are given an arbitrary object \( M \in \text{Alg}_{\mathcal{O}^\otimes / \mathcal{C}} \). Let \( A \) be the free \( \mathcal{O} \)-algebra generated by \( M \), so that each point \( \eta \in \text{Bin}(\mathcal{O}) \) determines a map

\[
\psi : \text{Free}(M(a_-)) \otimes_\eta \text{Free}(M(a_+)) \rightarrow A \otimes_\eta A
\]

Proposition 5.3.3.30 asserts that if each of the multiplication maps \( M(\gamma) : M(a_-) \otimes_\gamma M(a_+) \rightarrow M(a_\pm) \) is an equivalence, then \( \psi \) is also an equivalence. One might ask if the full strength of this hypothesis is really necessary: perhaps it is enough to require that the map \( M(\eta) \) is an equivalence? We will prove this in the special case \( \mathcal{O}^\otimes = \mathbb{A}_{\text{ss}}^\otimes \) (note that it is a trivial consequence of Proposition 5.3.3.30 if \( \mathcal{O}^\otimes = \mathbb{E}_k^\otimes \) for \( k \geq 1 \), since the space \( \text{Bin}(\mathcal{O}) \simeq S^{k-1} \) is connected).

**Proposition 5.3.3.32.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits small colimits for which the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C} \) preserves small colimits in each variable. Let \( M \in \text{Alg}_{\mathcal{O}^\otimes / \mathbb{A}_{\text{ss}}^\otimes} \) and let \( A \in \text{Alg}(\mathcal{C}) \) be the free associative algebra generated by \( M \). Assume that the canonical map \( M(a_-) \otimes M(a_+) \rightarrow M(a_\pm) \) is an equivalence. Then the composite map

\[
\text{Free}(M(a_-)) \otimes \text{Free}(M(a_+)) \rightarrow A \otimes A \rightarrow A
\]

is an equivalence in the \( \infty \)-category \( \mathcal{C} \).

**Warning 5.3.3.33.** In the situation of Proposition 5.3.3.32, the map

\[
\text{Free}(M(a_+)) \otimes \text{Free}(M(a_-)) \rightarrow A \otimes A \rightarrow A
\]

obtained by multiplying in the reverse order need not be an equivalence.

**Remark 5.3.3.34.** In more concrete terms, Proposition 5.3.3.32 asserts that the free algebra \( A \) is given (as an object of \( \mathcal{C} \)) by the coproduct

\[
\amalg_{m,n \geq 0} M(a_-)^{\otimes m} \otimes M(a_+)^{\otimes n}.
\]

**Proof of Proposition 5.3.3.32.** Let \( K \) be as in proof of Proposition 5.3.3.19. Unwinding the definitions, we can identify \( K \) with the nerve of the category \( J \) which may be described as follows:

- The objects of \( J \) are triples \( (\langle n \rangle, S, T) \) where \( S \) and \( T \) are pointed subsets of \( \langle n \rangle \) satisfying \( S \cup T = \langle n \rangle \).
- A morphism from \( (\langle n \rangle, S, T) \) to \( (\langle n' \rangle, S', T') \) in \( J \) is a map of pointed sets \( \langle n \rangle \rightarrow \langle n' \rangle \) which restricts to a monotone map \( \langle n \rangle^\circ \rightarrow \langle n' \rangle^\circ \) and induces bijections \( S \simeq S' \) and \( T \simeq T' \).

Unwinding the definitions, we see that the free algebra \( A \) can be identified (as an object of \( \mathcal{C} \)) with the colimit of a diagram \( \phi : N(J) \rightarrow \mathcal{C} \) given on objects by the formula

\[
\phi(\langle n \rangle, S, T) = \bigotimes_{1 \leq i \leq n} \begin{cases} M(a_-) & \text{if } i \in S, i \notin T \\ M(a_+) & \text{if } i \in T, i \notin S \\ M(a_\pm) & \text{if } i \in S \cap T. \end{cases}
\]
Note that the nerve $N(J)$ can be decomposed as a disjoint union $\Pi_{p,q \geq 0} N(J_{p,q})$, where $J_{p,q}$ denotes the full subcategory of $J$ spanned by those objects $((n), S, T)$ where $|S \cap (n)^\circ| = p$ and $|T \cap (n)^\circ| = q$. Let $\phi_{p,q}$ denote the restriction of $\phi$ to $N(J_{p,q})$, so that $A$ is given by a coproduct of colimits

$$\Pi_{p,q \geq 0} \lim\phi_{p,q}.$$  

Under this identification, the map $Free(M(a_-)) \otimes Free(M(a_+)) \to A$ is given by a coproduct of maps

$$f_{p,q} : \phi_{p,q}(⟨p+q⟩, {∗, 1, …, p}; {∗, p+1, …, p+q}) \to \lim\phi_{p,q}.$$  

It will therefore suffice to show that each of the maps $f_{p,q}$ is an equivalence.

We will proceed by induction on $p$. Note first that if $p = 0$, then $J_{p,q}$ is comprised of the single object $((p+q), {∗, 1, …, p}; {∗, p+1, …, p+q})$ and there is nothing to prove. To handle the case $p > 0$, we first define the disorder of an object $⟨(n), S, T⟩$ to be the least element of $S \cap (n)^\circ$. For each integer $i > 0$, we let $J_i^+$ denote the full subcategory of $J_{p,q}$ spanned by those objects of disorder $\leq i$, and we let $J_i \subseteq J_i^+$ be the full subcategory spanned by those objects $⟨(n), S, T⟩$ which either have disorder $< i$ or satisfy $i \in S − T$. Note that the canonical map

$$\phi(⟨p+q⟩, {∗, 1, …, p}; {∗, p+1, …, p+q}) \to \lim\phi|_{N(J_i^+)}$$

can be identified with the tensor product of $f_{p-1,q}$ with the identity map from $M(a_-)$ to itself, and is therefore an equivalence by virtue of the inductive hypothesis. It will therefore suffice to show that each of the canonical maps

$$\lim\phi|_{N(J_i^+)} \to \lim\phi|_{N(J_i)} \to \lim\phi|_{N(J_2)} \to \cdots$$

are equivalences. This follows from the following pair of observations:

(a) For $i > 0$, the functor $\phi|_{N(J_i^+)}$ is a left Kan extension of $\phi|_{N(J_i)}$. To prove this, we observe that if $⟨(n), S, T⟩$ is any object of $J_i^+$ which does not belong to $J_i$, then the fiber product $J_i \times_{J_i^+} ⟨(n), S, T⟩$ has a final object $⟨(n+1), S', T'⟩$. Moreover, the map $\phi(⟨(n+1), S', T'⟩) \to \phi(⟨n), S, T⟩)$ is an equivalence in $\mathcal{C}$ by virtue of our assumption that the map $M(a_-) \otimes M(a_+) \to M(a_0)$ is an equivalence.

(b) For $i > 0$, the inclusion $N(J_i^+) \hookrightarrow N(J_{i+1})$ admits a left adjoint, and is therefore left cofinal.

\[\square\]

### 5.4 Little Cubes and Manifold Topology

Fix an integer $k \geq 0$. In Definition 5.1.0.2 we introduced the $\infty$-operad $\mathbb{E}_k^O$ of little $k$-cubes. The underlying $\infty$-category $\mathbb{E}_k^O$ has a unique object, which we can think of as an abstract open cube $\square_k^0$ of dimension $k$. The morphisms in $\mathbb{E}_k^O$ are described by rectilinear embeddings from $\square_k^0$ to itself. There are a number of variants on Definition 5.1.0.2, where the condition that an embedding $i : \square_k^0 \hookrightarrow \square_k^0$ be rectilinear is replaced by the requirement that $i$ preserve some other structure. We will describe a number of these variants in §5.4.2. For our purposes, the main case of interest is that in which we require all of our cubes to be equipped with an open embedding into a topological manifold $M$ of dimension $k$. The collection of such cubes can be organized into an $\infty$-operad $\mathbb{E}_M^O$ which we will study in §5.4.5. The study of this $\infty$-operad will require some results from point-set topology concerning open immersions between topological manifolds, which we will review in §5.4.1.

The $\infty$-operad $\mathbb{E}_M^O$ will play a central role in our discussion of topological chiral homology in §5.5. In the latter context it is sometimes convenient to work with nonunital $\mathbb{E}_M^O$-algebras: that is, algebras over the closely related $\infty$-operad $(\mathbb{E}_M^O)_\text{nu} \subseteq \mathbb{E}_M^O$ obtained by removing all 0-ary operations. It is therefore useful to understand the relationship between unital and nonunital algebras over an $\infty$-operad $O^O$. We will consider this problem first for associative algebras in §5.4.3 (using a variation on formalism developed in §4.7.2) and then for $\mathbb{E}_k$-algebras in §5.4.4 (from which it is easy to deduce analogous results for $\mathbb{E}_M$-algebras; see Proposition 5.4.5.14).
Convention 5.4.0.1. Unless otherwise specified, the word manifold will refer to a paracompact Hausdorff topological manifold of some fixed dimension $k$.

5.4.1 Embeddings of Topological Manifolds

In this section, we will review some classical results in point-set topology concerning embeddings between topological manifolds of the same dimension. We begin by stating a parametrized version of Brouwer’s invariance of domain theorem (a proof will be given at the end of this section).

**Theorem 5.4.1.1 (Brouwer).** Let $M$ and $N$ be manifolds of dimension $k$, and let $S$ be an arbitrary topological space. Suppose we are given a continuous map $f : M \times X \to N \times X$ satisfying the following pair of conditions:

(i) The diagram

\[
\begin{array}{ccc}
M \times X & \xrightarrow{f} & N \times X \\
\downarrow & & \downarrow \\
X & \xrightarrow{\text{inclusion}} & X
\end{array}
\]

is commutative.

(ii) The map $f$ is injective.

Then $f$ is an open map.

**Remark 5.4.1.2.** When $X$ is a single point, Theorem 5.4.1.1 was proven by Brouwer in [26].

**Corollary 5.4.1.3.** Let $M$ and $N$ be manifolds of the same dimension, and let $f : M \times X \to N \times X$ be a continuous bijection which commutes with the projection to $X$. Then $f$ is a homeomorphism.

Let $M$ and $N$ be topological manifolds of the same dimension. We let $\text{Emb}(M,N)$ denote the set of all open embeddings $M \hookrightarrow N$. We will regard $\text{Emb}(M,N)$ as a topological space: it is a subspace of the collection of all continuous maps from $M$ to $N$, which we endow with the compact-open topology. We let $\text{Homeo}(M,N)$ denote the set of all homeomorphisms of $M$ with $N$, regarded as a subspace of $\text{Emb}(M,N)$. For $k \geq 0$, we let $\text{Top}(k)$ denote the topological group $\text{Homeo}(\mathbb{R}^k, \mathbb{R}^k)$ of homeomorphisms from $\mathbb{R}^k$ to itself.

**Remark 5.4.1.4.** Let $M$ and $N$ be topological manifolds of the same dimension, and let $\text{Map}(M,N)$ denote the set of all continuous maps from $M$ to $N$, endowed with the compact-open topology. Since $M$ is locally compact, $\text{Map}(M,N)$ classifies maps of topological spaces from $M$ to $N$: that is, for any topological space $X$, giving a continuous map $X \to \text{Map}(M,N)$ is equivalent to giving a continuous map $M \times X \to N$, which is in turn equivalent to giving a commutative diagram

\[
\begin{array}{ccc}
M \times X & \xrightarrow{f} & N \times X \\
\downarrow & & \downarrow \\
X & \xrightarrow{\text{inclusion}} & X
\end{array}
\]

Under this equivalence, continuous maps from $X$ to $\text{Emb}(M,N)$ correspond to commutative diagrams as above where $f$ is injective (hence an open embedding, by Theorem 5.4.1.1), and continuous maps from $X$ to $\text{Homeo}(M,N)$ correspond to commutative diagrams as above where $f$ is bijective (and therefore a homeomorphism, by Theorem 5.4.1.1). It follows that the space of embeddings $\text{Emb}(M,M)$ has the structure of a topological monoid, and that $\text{Homeo}(M,M)$ has the structure of a topological group.

In §5.4.2, we will need the to know that the topological monoid $\text{Emb}(\mathbb{R}^k, \mathbb{R}^k)$ is grouplike: that is, the set of path components $\pi_0 \text{Emb}(\mathbb{R}^k, \mathbb{R}^k)$ forms a group under composition. This is an immediate consequence of the following version of the Kister-Mazur theorem, whose proof we defer until the end of this section.
Theorem 5.4.1.5 (Kister-Mazur). For each $k \geq 0$, the inclusion $\text{Top}(k) \hookrightarrow \text{Emb}(\mathbb{R}^k, \mathbb{R}^k)$ is a homotopy equivalence.

We now describe some variants on the embedding spaces $\text{Emb}(M, N)$ and their homotopy types.

Definition 5.4.1.6. Let $M$ be a topological manifold of dimension $k$, let $S$ be a finite set, and for every positive real number $t$ let $B(t) \subset \mathbb{R}^k$ be as in Lemma 5.4.1.7. We let $\text{Germ}(S, M)$ denote the simplicial set $\lim_{\to \infty} \text{Sing}\text{Emb}(B(\frac{1}{n}) \times S, M)$. We will refer to $\text{Germ}(S, M)$ as the simplicial set of $S$-germs in $M$.

Lemma 5.4.1.7. Let $M$ be a topological manifold of dimension $k$ and $S$ a finite set. For every positive real number $t$, let $B(t) \subset \mathbb{R}^k$ denote the open ball of radius $t$. For every pair of positive real numbers $s < t$, the restriction map $r : \text{Emb}(B(t) \times S, M) \to \text{Emb}(B(s) \times S, M)$ is a homotopy equivalence.

Proof. This follows from the observation that the embedding $B(s) \hookrightarrow B(t)$ is isotopic to a homeomorphism. \qed

By repeated application of Lemma 5.4.1.7 we deduce the following:

Proposition 5.4.1.8. Let $M$ be a topological manifold of dimension $k$ and let $S$ be a finite set. Then the obvious restriction map $\text{Sing}\text{Emb}(\mathbb{R}^k \times S, M) \to \text{Germ}(S, M)$ is a homotopy equivalence of Kan complexes.

Notation 5.4.1.9. Let $M$ be a topological manifold of dimension $k$. Evaluation at the origin $0 \in \mathbb{R}^k$ induces a map $\theta : \text{Emb}(\mathbb{R}^k, M) \to M$. We will denote the fiber of this map over a point $x \in M$ by $\text{Emb}_x(\mathbb{R}^k, M)$. The map $\theta$ is a Serre fibration, so we have a fiber sequence of topological spaces

$$\text{Emb}_x(\mathbb{R}^k, M) \to \text{Emb}(\mathbb{R}^k, M) \to M.$$ 

We let $\text{Germ}(M)$ denote the simplicial set $\text{Germ}(\{\ast\}, M)$. Evaluation at 0 induces a Kan fibration $\text{Germ}(M) \to \text{Sing} M$; we will denote the fiber of this map over a point $x \in M$ by $\text{Germ}_x(M)$. We have a map of fiber sequences

$$\begin{CD}
\text{Sing}\text{Emb}_x(\mathbb{R}^k, M) @>>> \text{Sing}\text{Emb}(\mathbb{R}^k, M) @>>> \text{Sing} M \\
@VV\psi V @VV\psi' V @VV\psi'' V \\
\text{Germ}_x(M) @>>> \text{Germ}(M) @>>> \text{Sing} M.
\end{CD}$$

Since $\psi'$ is a homotopy equivalence (Proposition 5.4.1.8) and $\psi''$ is an isomorphism, we conclude that $\psi$ is a homotopy equivalence.

The simplicial set $\text{Germ}_0(\mathbb{R}^k)$ forms a simplicial group with respect to the operation of composition of germs. Since $\mathbb{R}^k$ is contractible, we have homotopy equivalences of simplicial monoids

$$\text{Germ}_0(\mathbb{R}^k) \hookrightarrow \text{Sing}\text{Emb}_x(\mathbb{R}^k, \mathbb{R}^k) \to \text{Sing}\text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \hookrightarrow \text{Sing}\text{Top}(k)$$

(see Theorem 5.4.1.5): in other words, $\text{Germ}_0(\mathbb{R}^k)$ can be regarded as a model for the homotopy type of the topological group $\text{Top}(k)$.

Remark 5.4.1.10. For any topological $k$-manifold $M$, the group $\text{Germ}_0(\mathbb{R}^k)$ acts on $\text{Germ}(M)$ by composition. This action is free, and we have a canonical isomorphism of simplicial sets $\text{Germ}(M)/\text{Germ}_0(\mathbb{R}^k) \simeq \text{Sing} M$.

Remark 5.4.1.11. Let $j : U \to M$ be an open embedding of topological $k$-manifolds and $S$ a finite set. Then evaluation at 0 determines a diagram of simplicial sets

$$\begin{CD}
\text{Sing}\text{Emb}(\mathbb{R}^k \times S, U) @>>> \text{Sing}\text{Emb}(\mathbb{R}^k \times S, M) \\
@VVV @VVV \\
\text{Conf}(S, U) @>>> \text{Conf}(S, M).
\end{CD}$$
We claim that this diagram is homotopy Cartesian. In view of Proposition 5.4.1.8, it suffices to show that the equivalent diagram

\[
\begin{array}{ccccc}
\text{Germ}(S, U) & \longrightarrow & \text{Germ}(S, M) \\
\downarrow & & \downarrow \\
\text{Conf}(S, U) & \longrightarrow & \text{Conf}(S, M),
\end{array}
\]

is homotopy Cartesian. This diagram is a pullback square and the vertical maps are Kan fibrations: in fact, the vertical maps are principal fibrations with structure group \(\text{Germ}(\mathbb{R}^k)^5\).

Taking \(U = \mathbb{R}^k\), and \(S\) to consist of a single point, we have a larger diagram

\[
\begin{array}{ccccc}
\text{Sing Emb}_0(\mathbb{R}^k, \mathbb{R}^k) & \longrightarrow & \text{Sing Emb}(\mathbb{R}^k, \mathbb{R}^k) & \longrightarrow & \text{Sing Emb}(\mathbb{R}^k, M) \\
\downarrow & & \downarrow & & \downarrow \\
\{0\} & \longrightarrow & \text{Sing} \mathbb{R}^k & \longrightarrow & \text{Sing} M.
\end{array}
\]

Since the horizontal maps on the left are homotopy equivalences of Kan complexes, we obtain a homotopy fiber sequence of Kan complexes

\[
\text{Sing Emb}_0(\mathbb{R}^k, \mathbb{R}^k) \rightarrow \text{Sing Emb}(\mathbb{R}^k, M) \rightarrow \text{Sing} M.
\]

We conclude this section with the proofs of Theorems 5.4.1.1 and 5.4.1.5.

**Proof of Theorem 5.4.1.1.** Fix a continuous map \(f : M \times X \rightarrow N \times X\) and an open set \(U \subseteq M \times X\); we wish to show that \(f(U)\) is open in \(N \times X\). In other words, we wish to show that for each \(u = (m, x) \in U\), the set \(f(U)\) contains a neighborhood of \(f(u) = (n, x)\) in \(N \times S\). Since \(N\) is a manifold, there exists an open neighborhood \(V \subseteq N\) containing \(n\) which is homeomorphic to Euclidean space \(\mathbb{R}^k\). Replacing \(N\) by \(V\) (and shrinking \(M\) and \(X\) as necessary), we may assume that \(N \simeq \mathbb{R}^k\). Similarly, we can replace \(M\) and \(X\) by small neighborhoods of \(m\) and \(s\) to reduce to the case where \(M \simeq \mathbb{R}^k\) and \(U = M \times X\).

We first treat the case where \(X\) consists of a single point. Let \(D \subseteq M\) be a closed neighborhood of \(m\) homeomorphic to a (closed) \(k\)-dimensional disk, and regard \(N\) as an open subset of the \(k\)-sphere \(S^k\). We have a long exact sequence of compactly supported cohomology groups

\[
0 \simeq H_{c-1}^k(S^k; \mathbb{Z}) \rightarrow H_{c-1}^k(f(\partial D); \mathbb{Z}) \rightarrow H_{c}^k(S^k - f(\partial D); \mathbb{Z}) \rightarrow H_{c}^k(S^k; \mathbb{Z}) \rightarrow H_{c}^k(f(\partial D); \mathbb{Z}) \simeq 0.
\]

Since \(f\) is injective, \(f(\partial D)\) is homeomorphic to a \((k - 1)\)-sphere. It follows that \(H_{c}^k(S^k - f(\partial D); \mathbb{Z})\) is a free \(\mathbb{Z}\)-module of rank 2, so that (by Poincare duality) the ordinary cohomology \(H^0(S^k - f(\partial D); \mathbb{Z})\) is also free of rank 2: in other words, the open set \(S^k - f(\partial D)\) has exactly two connected components. We have another long exact sequence

\[
0 \simeq H_{c-1}^k(f(D); \mathbb{Z}) \rightarrow H_{c}^k(S^k - f(\partial D); \mathbb{Z}) \rightarrow H_{c}^k(S^k; \mathbb{Z}) \rightarrow H_{c}^k(f(D); \mathbb{Z}) \simeq 0.
\]

This proves that \(H_{c}^k(S^k - f(D); \mathbb{Z})\) is free of rank 1 so that (by Poincare duality) \(S^k - f(D)\) is connected. The set \(S^k - f(\partial D)\) can be written as a union of connected sets \(f(D - \partial D)\) and \(S^k - f(\partial D)\), which must therefore be the connected components of \(S^k - f(\partial D)\). It follows that \(f(D - \partial D)\) is open \(S^k\) so that \(f(M)\) contains a neighborhood of \(f(m)\) as desired.

Let us now treat the general case. Without loss of generality, we may assume that \(f(u) = (0, x)\), where \(x \in X\) and 0 denotes the origin of \(\mathbb{R}^k\). Let \(f_x : M \rightarrow N\) be the restriction of \(f\) to \(M \times \{x\}\). The above argument shows that \(f_x\) is an open map, so that \(f_x(M)\) contains a closed ball \(\overline{B(\epsilon)} \subseteq \mathbb{R}^k\) for some positive radius \(\epsilon\). Let \(S \subseteq M - \{m\}\) be the inverse image of the boundary \(\partial B(\epsilon)\), so that \(S\) is homeomorphic to the \((k - 1)\)-sphere. In particular, \(S\) is compact. Let \(\pi : M \times X \rightarrow \mathbb{R}^k\) denote the composition of \(f\) with the projection map \(N \times X \rightarrow N \simeq \mathbb{R}^k\). Shrinking \(X\) if necessary, we may suppose
that the distance $d(f(s, x), f(s, y)) < \frac{\epsilon}{2}$ for all $s \in S$ and all $y \in X$. We will complete the proof by showing that $B(\frac{\epsilon}{2}) \times X$ is contained in the image of $f$. Supposing otherwise; then there exists $v \in B(\frac{\epsilon}{2})$ and $y \in X$ such that $(v, y) \notin f(M \times X)$. Then $f_y$ defines a map from $M$ to $\mathbb{R}^k - \{v\}$, so the restriction $f_y|S$ is nullhomotopic when regarded as a map from $S$ to $\mathbb{R}^k - \{v\}$. However, this map is homotopic (via a straight-line homotopy) to $f_y|S$, which carries $S$ homeomorphically onto $\partial B(\epsilon) \subseteq \mathbb{R}^k - \{v\}$. It follows that the inclusion $\partial B(\epsilon) \subseteq \mathbb{R}^k - \{v\}$ is nullhomotopic, which is impossible. \qed

We now turn to the proof of Theorem 5.4.1.5. The main step is the following technical result:

**Lemma 5.4.1.12.** Let $X$ be a paracompact topological space, and suppose that there exists a continuous map $f_0 : \mathbb{R}^k \times X \to \mathbb{R}^k$ such that, for each $x \in X$, the restriction $f_{0,x} = f_0|\mathbb{R}^k \times \{x\}$ is injective. Then there exists an isotopy $f : \mathbb{R}^k \times X \times [0, 1] \to \mathbb{R}^k$ with the following properties:

(i) The restriction $f|\mathbb{R}^k \times X \times \{0\}$ coincides with $f_0$.

(ii) For every pair $(x, t) \in X \times [0, 1]$, the restricted map $f_{t,x} = f|\mathbb{R}^k \times \{x\} \times \{t\}$ is injective.

(iii) For each $x \in X$, the map $f_{1,x}$ is bijective.

(iv) Suppose $x \in X$ has the property that $f_{0,x}$ is bijective. Then $f_{t,x}$ is bijective for all $t \in [0, 1]$.

*Proof.* Let $w : X \to \mathbb{R}^k$ be given by the formula $w(x) = f_0(0, x)$. Replacing $f_0$ by the map $(v, x) \mapsto f_0(v, x) - w(x)$, we can reduce to the case where $w = 0$: that is, each of the maps $f_{0,x}$ carries the origin of $\mathbb{R}^k$ to itself.

For every continuous positive real-valued function $\epsilon : X \to \mathbb{R}_{>0}$, we let $B(\epsilon)$ denote the open subset of $\mathbb{R}^k \times X$ consisting of those pairs $(v, x)$ such that $|v| < \epsilon(x)$. If $r$ is a real number, we let $B(r) = B(\epsilon)$, where $\epsilon : X \to \mathbb{R}_{>0}$ is the constant function taking the value $r$.

Let $g^1 : \mathbb{R}^k \times X \to \mathbb{R}^k \times X$ be given by the formula $g^1(v, x) = (f_1(v, x), x)$. The image $g^1(B(1))$ is an open subset of $\mathbb{R}^k \times X$ (Theorem 5.4.1.1) which contains the zero section $\{0\} \times X$; it follows that $g^1(B(1))$ contains $B(\epsilon)$ for some positive real-valued continuous function $\epsilon : X \to \mathbb{R}_{>0}$. Replacing $f_0$ by the function $(v, x) \mapsto f_0(v, x)$, we can assume that $B(1) \subseteq g^1(B(1))$.

We now proceed by defining a sequence of open embeddings $\{g^i : \mathbb{R}^k \times X \to \mathbb{R}^k \times X\}_{i \geq 2}$ and isotopies $\{h^i_t\}_{0 \leq t \leq 1}$ from $g^i$ to $g^{i+1}$, so that the following conditions are satisfied:

(a) Each of the maps $g^i$ is compatible with the projection to $X$.

(b) Each isotopy $\{h^i_t\}_{0 \leq t \leq 1}$ consists of open embeddings $\mathbb{R}^k \times X \to \mathbb{R}^k \times X$ which are compatible with the projection to $X$. Moreover, this isotopy is constant on the open set $B(i) \subseteq \mathbb{R}^k \times X$.

(c) For $i \geq 1$, we have $B(i) \subseteq g^i(B(i))$.

(d) Let $x \in X$ be such that the map $g^i_x : \mathbb{R}^k \to \mathbb{R}^k$ is a homeomorphism. Then $h^i_{t,x} : \mathbb{R}^k \to \mathbb{R}^k$ is a homeomorphism for all $t \in [0, 1]$.

Assuming that these requirements are met, we can obtain the desired isotopy $f_t$ by the formula

$$f_t(v, x) = \begin{cases} \pi g^i(v, x) & \text{if } (|v| < i) \land (t > 1 - \frac{1}{i + 1}) \\ \pi h^i_t(v, x) & \text{if } t = 1 + \frac{s - 2}{i + 1}, \end{cases}$$

where $\pi$ denotes the projection from $\mathbb{R}^k \times X$ onto $\mathbb{R}^k$. We now proceed by induction on $i$. Assume that $g^i$ has already been constructed; we will construct an isotopy $h^i$ from $g^i$ to another open embedding $g^{i+1}$ to satisfy the above conditions. First, we need to establish a bit of notation.

For every pair of real numbers $r < s$, let $\{H(r, s)_i : \mathbb{R}^k \to \mathbb{R}^k\}_{0 \leq t \leq 1}$ be a continuous family of homeomorphisms satisfying the following conditions:
(i) The isotopy \( \{H(r,s)\}_r \) is constant on \( \{v \in \mathbb{R}^k : |v| < \frac{\epsilon}{2}\} \) and \( \{v \in \mathbb{R}^k : |v| > s + 1\} \).

(ii) The map \( H(r,s) \) restricts to a homeomorphism of \( B(r) \) with \( B(s) \).

We will assume that the homeomorphisms \( \{H(r,s)\}_r \) are chosen to depend continuously on \( r \), \( s \), and \( t \). Consequently, if \( \epsilon < \epsilon' \) are positive real-valued functions on \( X \), we obtain an isotopy \( \{H(\epsilon, \epsilon')\}_t : \mathbb{R}^k \times X \to \mathbb{R}^k \times X \) by the formula \( H(\epsilon, \epsilon')(x,v) = (H(\epsilon(x), \epsilon'(x)), v) \).

Since \( g^i \) is continuous and \( \{0\} \times X \subseteq (g^i)^{-1}B(\frac{1}{2}) \), there exists a real-valued function \( \delta : X \to (0, 1) \) such that \( g^i(B(\delta)) \subseteq B(\frac{1}{2}) \). We define a homeomorphism \( c : \mathbb{R}^k \times X \to \mathbb{R}^k \times X \) as follows:

\[
c(v,x) = \begin{cases} 
(v, x) & \text{if } (v,x) \notin g^i(\mathbb{R}^k \times X) \\
g^i(H(\delta(x), i)^{-1}(w), x) & \text{if } (v,x) = g^i(w,x).
\end{cases}
\]

Since \( g^i \) carries \( B(\delta) \) into \( B(\frac{1}{2}) \), we deduce that \( c(g^i(v,x)) \in B(\frac{1}{2}) \) if \( (v,x) \in B(i) \). Note that \( c \) is the identity outside of the image \( g^iB(i + 1) \); we can therefore choose a positive real valued function \( \epsilon : X \to (i + 1, \infty) \) such that \( c \) is the identity outside of \( B(\epsilon) \).

We now define \( h^i \) by the formula \( h^i = c^{-1} \circ H(1, \epsilon) \circ c \circ g^i \) (here we identify the real number \( 1 \in \mathbb{R} \) with the constant function \( X \to \mathbb{R} \) taking the value \( 1 \)). It is clear that \( h^i \) is an isotopy from \( g^i = g_0^i \) to another map \( g^{i+1} = g_1^i \), satisfying conditions \( (a) \) and \( (d) \) above. Since \( H(1, \epsilon) \) is the identity on \( \mathbb{R}(\frac{1}{2}) \) and \( c \circ g^i \) carries \( B(i) \) into \( B(\frac{1}{2}) \), we deduce that \( h^i \) is constant on \( B(i) \) so that \( (b) \) is satisfied. It remains only to verify \( (c) \): we must show that \( g^{i+1}B(i + 1) \) contains \( B(i + 1) \). In fact, we claim that \( g^{i+1}B(i + 1) \) contains \( B(\epsilon) \). Since \( c \) is supported in \( B(\epsilon) \), it suffices to show that \( (c g^{i+1})B(i + 1) = (H(1, \epsilon) \circ c \circ g^i)B(i + 1) \) contains \( B(\epsilon) \). This we need only show that \( (c \circ g^i)B(i + 1) \) contains \( B(1) \subseteq B(i) \subseteq g^iB(i) \subseteq g^iB(i + 1) \). This is clear, since \( H(\delta(x), i)_1 \) induces a homeomorphism of \( B(i + 1) \) with itself.

\[\square\]

Proof of Theorem 5.4.1.5. For every compact set \( K \subseteq \mathbb{R}^k \), the compact open topology on the set of continuous maps \( \text{Map}(K, \mathbb{R}^k) \) agrees with the topology induced by the metric \( d_K(f,g) = \sup\{|f(v) - g(v)|, v \in K\} \). Consequently, the compact open topology on the entire mapping space \( \text{Map}(\mathbb{R}^k, \mathbb{R}^k) \) is defined by the countable sequence of metrics \( \{d_{\mathbb{B}(n)}\}_{n \geq 0} \) (here \( \mathbb{B}(n) \) denotes the closed ball of radius \( n \)), or equivalently by the single metric

\[d(f,g) = \sum_{n \geq 0} \frac{1}{2^n} \inf\{1, d_{\mathbb{B}(n)}(f,g)\}.\]

It follows that \( \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \subseteq \text{Map}(\mathbb{R}^k, \mathbb{R}^k) \) is metrizable and therefore paracompact. Applying Lemma 5.4.1.12 to the canonical pairing

\[f_0 : \mathbb{R}^k \times \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \to \mathbb{R}^k \times \text{Map}(\mathbb{R}^k, \mathbb{R}^k) \to \mathbb{R}^k,\]

we deduce the existence of an map \( f : \mathbb{R}^k \times \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \times [0, 1] \to \mathbb{R}^k \) which is classified by a homotopy \( \chi : \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \times [0, 1] \to \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \) from \( id_{\text{Emb}(\mathbb{R}^k, \mathbb{R}^k)} \) to some map \( s : \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \to \text{Homeo}(\mathbb{R}^k, \mathbb{R}^k) \).

We claim that \( s \) is a homotopy inverse to the inclusion \( i : \text{Homeo}(\mathbb{R}^k, \mathbb{R}^k) \to \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \). The homotopy \( \chi \) shows that \( i s = \text{homeo} \) to the identity on \( \text{Emb}(\mathbb{R}^k, \mathbb{R}^k) \), and the restriction of \( \chi \) to \( \text{Homeo}(\mathbb{R}^k, \mathbb{R}^k) \times [0, 1] \) shows that \( s i \) is homotopic to the identity on \( \text{Homeo}(\mathbb{R}^k, \mathbb{R}^k) \).
(1) The objects of $i^*\mathcal{E}_{\text{BT}(k)}^\bullet$ are the objects $(n) \in \mathcal{F}_{\text{Fin}}$.

(2) Given a pair of objects $(m), (n) \in i^*\mathcal{E}_{\text{BT}(k)}^\bullet$, the mapping space $\text{Map}_{\mathcal{F}_{\text{Fin}}}((m), (n))$ is given by the disjoint union

$$\coprod_{\alpha} \prod_{1 \leq i \leq n} \text{Emb}(R^k \times \alpha^{-1}(i), R^k)$$

taken over all morphisms $\alpha : (m) \to (n)$ in $\mathcal{F}_{\text{Fin}}$.

We let $\text{BT}(k)^\circ$ denote the $\infty$-category given by the homotopy coherent nerve $N(i^*\mathcal{E}_{\text{BT}(k)})^\circ$.

**Remark 5.4.2.2.** It follows from Proposition 2.1.1.27 that $\text{BT}(k)^\circ$ is an $\infty$-operad.

**Remark 5.4.2.3.** Definition 5.4.2.1 is a close relative of Definition 5.1.0.2. In fact, choosing a homeomorphism $\text{BT}(k)^\circ$, we obtain an inclusion of $\infty$-operads $E_k^\circ \to \text{BT}(k)^\circ$.

**Remark 5.4.2.4.** The object $(0)$ is initial in $\text{BT}(k)^\circ$. It follows that $\text{BT}(k)^\circ$ is a unital $\infty$-operad.

**Example 5.4.2.5.** Suppose that $k = 1$. Every open embedding $j : R^k \times S \hookrightarrow R^k$ determines a pair $(<, \epsilon)$, where $<$ is an element of the set of linear orderings of $S$ (given by $s < s'$ if $j(0, s) < j(0, s')$) and $\epsilon : S \to \{\pm 1\}$ is a function defined so that $\epsilon(s) = 1$ if $j(R^k \times \{s\})$ is orientation preserving, and $\epsilon(s) = -1$ otherwise. This construction determines a homotopy equivalence $\text{Emb}(R^k \times S, R^k) \to L(S) \times \{\pm 1\}^S$, where $L(S)$ denotes the set of linear orderings of $S$. It follows that $\text{BT}(k)^\circ$ is equivalent to the nerve of its homotopy category and therefore arises from an operad in the category of sets via Construction 2.1.1.7. In fact, this is the operad which controls associative algebras with involution, as described in §2.3.4.

**Notation 5.4.2.6.** For each integer $k \geq 0$, we let $\text{BT}(k)$ denote the $\infty$-category $\text{BT}(k)^\circ \times N(\mathcal{F}_{\text{Fin}})\{1\}$ underlyng the $\infty$-operad $\text{BT}(k)^\circ$. Then $\text{BT}(k)$ can be identified with the nerve of the topological category having a single object whose endomorphism monoid is the space $\text{Emb}(R^k, R^k)$ of open embeddings from $R^k$ to itself. It follows from the Kister-Mazur theorem (Theorem 5.4.1.5) that $\text{Emb}(R^k, R^k)$ is a grouplike topological monoid, so that $\text{BT}(k)$ is a Kan complex. In fact, Theorem 5.4.1.5 shows that $\text{BT}(k)$ can be identified with a classifying space for the topological group $\text{Top}(k)$ of homeomorphisms from $R^k$ to itself.

**Remark 5.4.2.7.** We can modify Definition 5.4.2.1 by replacing the embedding spaces $\text{Emb}(R^k \times S, R^k)$ by the products $\prod_{s \in S} \text{Emb}(R^k, R^k)$. This yields another $\infty$-operad, which is canonically isomorphic to $\text{BT}(k)^H$. The evident inclusions $\text{Emb}(R^k \times S, R^k) \hookrightarrow \prod_{s \in S} \text{Emb}(R^k, R^k)$ induce an inclusion of $\infty$-operads $\text{BT}(k)^\circ \hookrightarrow \text{BT}(k)^H$.

If $k > 0$, then the Kan complex $\text{BT}(k)$ is not contractible (nor even simply-connected, since an orientation-reversing homeomorphism from $R^k$ to itself cannot be isotopic to the identity), so the $\infty$-operad $\text{BT}(k)^\circ$ is not reduced. Consequently, we can apply Theorem 2.3.4.4 to decompose $\text{BT}(k)^\circ$ as the assembly of a family of reduced $\infty$-operads. The key to understanding this decomposition is the following observation:

**Proposition 5.4.2.8.** Let $k$ be a nonnegative integer, and choose a homeomorphism $R^k \simeq \Box^k$. The induced inclusion $f : \mathcal{E}_k^\circ \to \text{BT}(k)^\circ$ is an approximation to $\text{BT}(k)^\circ$ (see Definition 2.3.3.6).

**Proof.** Using Corollaries 2.3.3.16 and 2.3.3.17, we are reduced to proving that for every finite set $S$, the diagram

$$
\begin{array}{ccc}
\text{Sing}(\text{Rect}(\Box^k \times S, \Box^k)) & \longrightarrow & \text{Sing}(\text{Rect}(\Box^k, \Box^k)^S) \\
\downarrow & & \downarrow \\
\text{Sing}(\text{Emb}(R^k \times S), R^k) & \longrightarrow & \text{Sing}(\text{Emb}(R^k, R^k)^S)
\end{array}
$$
Remark 5.4.2.9. Fix a nonnegative integer $k$. The $\infty$-operad $B\text{Top}(k)^\otimes$ is unital and its underlying $\infty$-category $B\text{Top}(k)$ is a Kan complex (Notation 5.4.2.6). According to Theorem 2.3.4.4, there exists a reduced generalized $\infty$-operad $\mathcal{O}^\otimes$ and an assembly map $\mathcal{O}^\otimes \to B\text{Top}(k)^\otimes$. Then $\mathcal{O}(0)^\otimes \simeq \emptyset \simeq B\text{Top}(k)$; we may therefore assume without loss of generality that $\mathcal{O}^\otimes \to B\text{Top}(k) \times N(\mathfrak{Im}_e)$ is a $B\text{Top}(k)$-family of $\infty$-operads. Since $E^\otimes_k$ is reduced, Theorem 2.3.4.4 guarantees that the inclusion $E^\otimes_k \to B\text{Top}(k)^\otimes$ factors (up to homotopy) through $\mathcal{O}_x^\otimes$. Without loss of generality, this map factors through $\mathcal{O}_x^\otimes$, where $x$ denotes the unique vertex of $B\text{Top}(k)$. The resulting map $E^\otimes_k \to \mathcal{O}_x^\otimes$ is a approximation to $\mathcal{O}_x^\otimes$ (Proposition 5.4.2.8). Since both $E^\otimes_k$ and $\mathcal{O}_x^\otimes$ are reduced, it is an equivalence (Corollary 2.3.3.24). We can summarize the situation as follows: the $\infty$-operad $B\text{Top}(k)^\otimes$ is obtained by assembling a reduced $B\text{Top}(k)$-family of $\infty$-operads, each of which is equivalent to $E^\otimes_k$. More informally, we can regard this $B\text{Top}(k)$-family as encoding an action of the loop space $\Omega B\text{Top}(k) \simeq \text{Sing} B\text{Top}(k)$ on the $\infty$-operad $E^\otimes_k$, so that $B\text{Top}(k)^\otimes$ can be regarded as a semidirect product of the $\infty$-operad $E^\otimes_k$ with the topological group $\text{Top}(k)$ of homeomorphisms of $R^k$ with itself.

We can summarize Remark 5.4.2.9 informally as follows: if $\mathcal{C}$ is a symmetric monoidal $\infty$-category, then the $\infty$-category $\text{Alg}_{\mathcal{B}\text{Top}(k)}(\mathcal{C})$ can be identified with the $\infty$-category of $E_k$-algebra objects of $\mathcal{C}$ which are equipped with a compatible action of the topological group $\text{Top}(k)$. The requirement that $\text{Top}(k)$ act on an $E_k$-algebra is rather strong: in practice, we often encounter situations where an algebra $A \in \text{Alg}_{\mathcal{B}\text{Top}(k)}(\mathcal{C})$ is acted on not by the whole of $\text{Top}(k)$, but by some smaller group. Our next definition gives a convenient formulation of this situation.

Definition 5.4.2.10. Let $B$ be a Kan complex equipped with a Kan fibration $B \to B\text{Top}(k)$. We let $E^\otimes_B$ denote the fiber product

$$B\text{Top}(k)^\otimes \times_{B\text{Top}(k)^\otimes} B^\Pi.$$ 

Remark 5.4.2.11. It follows immediately from the definitions that $E^\otimes_B$ is a unital $\infty$-operad and that the map $E^\otimes_B \to B\text{Top}(k)^\otimes$ is an approximation of $\infty$-operads.

Warning 5.4.2.12. Our notation is slightly abusive. The $\infty$-operad $E^\otimes_B$ depends not only on the Kan complex $B$, but also on the integer $k$ and the map $\theta : B \to B\text{Top}(k)$. We can think of $\theta$ as classifying a topological fiber bundle over the geometric realization $|B|$, whose fibers are homeomorphic to $R^k$. 

\[
\begin{align*}
\text{Sing(Rect}(\square^k \times S, \square^k)) & \longrightarrow \text{Sing Rect}(\square^k, \square^k)^S \\
\text{Sing(Emb}(R^k \times S, R^k)) & \longrightarrow \text{Sing(Emb}(R^k, R^k))^S \\
\text{Germ}(S, R^k) & \longrightarrow \prod_{s \in S} \text{Germ}({s}, R^k) \\
\text{Conf}(S, R^k) & \longrightarrow \prod_{s \in S} \text{Conf}({s}, R^k).
\end{align*}
\]
Remark 5.4.2.13. Let $\mathcal{O}^\otimes \to \text{BTop}(k) \times \text{N}(\text{Fin}_*)$ be the infinite-operad family of Remark 5.4.2.9. If $\theta : B \to \text{BTop}(k)$ is any map of Kan complexes, then the fiber product $\mathcal{O}^\otimes \times_{\text{BTop}(k)} B$ is a $B$-family of reduced unital infinite-operads. When $\theta$ is a Kan fibration (which may be assumed without loss of generality), then this $B$-family of infinite-operads assembles to the unital infinite-operad $E^\otimes_B$ (see §2.3.4). We can informally describe the situation as follows: an $E_B$-algebra object of a symmetric monoidal infinite-category $\mathcal{C}$ is a (twisted) family of $E_B$-algebra objects $C$, parametrized by Kan complex $B$ (the nature of the twisting is determined by the map $\theta$).

Remark 5.4.2.14. Let $k$ and $k'$ be integers. The homeomorphism $\mathbb{R}^{k+k'} \simeq \mathbb{R}^k \times \mathbb{R}^{k'}$ determines a map of Kan complexes $\text{BTop}(k) \times \text{BTop}(k') \to \text{BTop}(k+k')$. This map induces a bifunctor of infinite-operads $\text{BTop}(k)^H \times \text{BTop}(k')^H \to \text{BTop}(k+k')^H$ which restricts to a functor $\mathcal{O}(\text{BTop}(k))^\otimes \times \mathcal{O}(\text{BTop}(k'))^\otimes \to \mathcal{O}(\text{BTop}(k+k'))^\otimes$. More generally, if we are given maps of Kan complexes $B \to \text{BTop}(k)$ and $B' \to \text{BTop}(k')$, there is an induced bifunctor of infinite-operads

$$\theta_{B,B'} : E^\otimes_B \times E^\otimes_{B'} \to E^\otimes_{B \times B'}$$

where we regard $B \times B'$ as equipped with the composite map $B \times B' \to \text{BTop}(k) \times \text{BTop}(k') \to \text{BTop}(k+k')$ (classifying the sum of the bundles pulled back from $B$ and $B'$, respectively). The functor $\theta_{B,B'}$ exhibits $E^\otimes_{B \times B'}$ as a tensor product of the infinite-operads $E^\otimes_B$ and $E^\otimes_{B'}$. To prove this, we observe that Remark 5.4.2.13 implies that the constructions $B \mapsto E^\otimes_B$ and $B \mapsto E^\otimes_{B \times B'}$ carry homotopy colimits of Kan complexes (over $\text{Top}(k)$) to homotopy colimits of infinite-operads. Consequently, we may assume without loss of generality that $B \simeq \Delta^0$. Similarly, we may assume that $B' \simeq \Delta^0$. In this case, the bifunctor $\theta_{B,B'}$ is equivalent to bifunctor $E^\otimes_k \times E^\otimes_{k'} \to E^\otimes_{k+k'}$ appearing in the statement of Theorem 5.1.2.2.

We conclude this section by illustrating Definition 5.4.2.10 with some examples. Another general class of examples will be discussed in §5.4.5.

Example 5.4.2.15. Let $B$ be a contractible Kan complex equipped with a Kan fibration $B \to \text{BTop}(k)$. Then $E^\otimes_B$ is equivalent to the infinite-operad $E^\otimes_k$.

Example 5.4.2.16. Fix $k \geq 0$, and choose a homeomorphism of $\mathbb{R}^k$ with the unit ball $B(1) \subseteq \mathbb{R}^k$. We will say that a map $f : B(1) \to B(1)$ is a projective isometry if there exists an element $\gamma$ in the orthogonal group $O(k)$, a positive real number $\lambda$, and a vector $v_0 \in B(1)$ such that $f$ is given by the formula $f(w) = v_0 + \lambda \gamma(w)$. For every finite set $S$, we let $\text{Isom}(B(1) \times S, B(1))$ denote the (closed) subspace of $\text{Emb}(B(1) \times S, B(1))$ consisting of those open embeddings whose restriction to each ball $B(1) \times \{s\}$ is an orientation-preserving projective isometry. Let $\mathcal{C}_{\text{BTop}(k)}$ be the subcategory of $\mathcal{C}$ having the same objects, with morphism spaces given by

$$\text{Map}_{\mathcal{C}_{\text{BTop}(k)}}(\langle m \rangle, \langle n \rangle) = \prod_{1 \leq i \leq n} \text{Isom}(B(1) \times \alpha^{-1}\{i\}, B(1)).$$

Then $\mathcal{O}^\otimes = \text{N}(\mathcal{C}_{\text{BTop}(k)})$ is a unital infinite-operad. The inclusion $\mathcal{O}^\otimes \hookrightarrow \text{BTop}(k)^\otimes$ is an approximation of $\text{BTop}(k)^\otimes$ which induces an equivalence of $\mathcal{O}^\otimes$ with the infinite-operad $E_B$, where $B$ is a Kan complex that plays the role of a classifying space $\text{BSO}(k)$ for the special orthogonal group $SO(k)$ (and we arrange that the inclusion of topological groups $SO(k) \to \text{Top}(k)$ induces a Kan fibration $\text{BSO}(k) \to \text{BTop}(k)$). This recovers the operad of framed disks described, for example, in [124].

Variant 5.4.2.17. In Example 5.4.2.16, there is no need to restrict our attention to orientation preserving maps. If we instead allow all projective isometries, then we get another infinite-operad $\mathcal{O}^\otimes \simeq E^\otimes_B$, where $B$ is a classifying space for the full orthogonal group $O(k)$.

Example 5.4.2.18. In the definition of $\text{BTop}(k)^\otimes$, we have allowed arbitrary open embeddings between Euclidean spaces $\mathbb{R}^k$. We could instead restrict our attention to spaces of smooth open embeddings (which we regard as equipped with the Whitney topology, where convergence is given by uniform convergence of all derivatives on compact sets) to obtain an infinite-operad $E_{\text{Sm}}$. This can be identified with the infinite-operad $E_B$, where $B$ is a classifying space for the monoid of smooth embeddings from the open ball $B(1)$ to itself. Since every projective isometry is smooth, there is an obvious map $\mathcal{O}^\otimes \to E_{\text{Sm}}$, where $\mathcal{O}^\otimes$ is defined as
in Variant 5.4.2.17. In fact, this map is an equivalence of ∞-operads: this follows from the fact that the inclusion from the orthogonal group \(O(k)\) into the space \(\text{Emb}^{\text{nu}}_k(B(1), B(1))\) of smooth embeddings of \(B(1)\) to itself is a homotopy equivalence (it has a homotopy inverse given by the composition \(\text{Emb}^{\text{nu}}_k(B(1), B(1)) \to \text{GL}_k(R) \to O(k)\)), where the first map is given by taking the derivative at the origin and the second is a homotopy inverse to the inclusion \(O(k) \to \text{GL}_k(R)\).

Many other variants on Example 5.4.2.18 are possible. For example, we can replace smooth manifolds with piecewise linear manifolds. We can also consider smooth or piecewise linear manifolds equipped with additional structures, such as orientations. We leave the details to the reader.

### 5.4.3 Digression: Nonunital Associative Algebras and their Modules

Recall that a nonunital ring is an abelian group \((A, +)\) equipped with a bilinear and associative multiplication \(m : A \times A \to A\). Every associative ring determines a nonunital ring, simply by forgetting the multiplicative identity element. On the other hand, if \(A\) is an associative ring, then the ring structure on \(A\) is uniquely determined by underlying nonunital ring of \(A\). In other words, if \(A\) is a nonunital ring which admits a multiplicative identity \(1\), then \(1\) is uniquely determined. The proof is simple: if \(1\) and \(1'\) are both identities for the multiplication on \(A\), then \(1 = 1' = 1'\). Our goal in this section is to prove an ∞-categorical version of this result. More precisely, we will show that if \(A\) is a nonunital algebra object of a monoidal ∞-category \(\mathcal{C}\) which admits a (two-sided) unit up to homotopy, then \(A\) can be extended to an algebra object of \(\mathcal{C}\) in an essentially unique way (Theorem 5.4.3.8). In ordinary category theory, this is a tautology. However, in the ∞-categorical setting the result is not as obvious, since the unit of an algebra object \(A\) of \(\mathcal{C}\) is required to satisfy a hierarchy of coherence conditions with respect to the multiplication on \(A\).

We begin by recalling some basic definitions. Let \(\text{Comm}^\circ_{\text{nu}}\) denote the nonunital commutative ∞-operad: that is, the subcategory of \(\text{N}(\text{Fin}^\circ)\) whose morphisms are given by surjective maps \(\langle m \rangle \to \langle n \rangle\) of pointed finite sets (see Definition 5.4.4.1). We let \(\text{Ass}^\circ_{\text{nu}}\) denote the fiber product \(\text{Comm}^\circ_{\text{nu}} \times_{\text{Comm}^\circ} \text{Ass}^\circ\); we will refer to \(\text{Ass}^\circ_{\text{nu}}\) as the nonunital associative ∞-operad. Given a planar ∞-operad \(\mathcal{C}^\circ \to \text{Ass}^\circ\), we let \(\text{Alg}^\text{nu}(\mathcal{C})\) denote the ∞-category of nonunital associative algebra objects of \(\mathcal{C}\). For many purposes, it is convenient to have a slightly different model for the theory of nonunital associative algebras.

**Definition 5.4.3.1.** We will say that a morphism \([m] \to [n]\) in \(\Delta\) is inert if it determines an inert morphism in the ∞-operad \(\text{Ass}^\circ_{\text{nu}}\) that is, if it induces a bijection \([m] \simeq \{i, i + 1, \ldots, i + m\} \subseteq [n]\). If \(\mathcal{C}^\circ \to \text{N}(\Delta)^{\text{op}}\) is a ∆-planar ∞-operad, we let \(\Delta\text{Alg}^\text{nu}(\mathcal{C})\) denote the full subcategory of \(\text{Fun}_{\text{N}(\Delta)^{\text{op}}}^\circ(\text{N}(\Delta)^{\text{op}}, \mathcal{C}^\circ)\) spanned by those functors which carry inert morphisms in \(\text{N}(\Delta)^{\text{op}}\) to inert morphisms in \(\mathcal{C}^\circ\).

**Proposition 5.4.3.2.** Let \(\mathcal{C}^\circ \to \text{Ass}^\circ\) be a planar ∞-operad and let \(\mathcal{C}^\circ = \mathcal{C}^\circ \times_{\text{Ass}^\circ} \text{N}(\Delta)^{\text{op}}\) be the associated ∆-planar ∞-operad. Then composition with the map \(\text{N}(\Delta)^{\text{op}} \to \text{Ass}^\circ_{\text{nu}}\) of Proposition 5.4.3.3 induces an equivalence of ∞-categories \(\text{Alg}^\text{nu}(\mathcal{C}) \to \Delta\text{Alg}^\text{nu}(\mathcal{C})\).

**Proof.** Combine Proposition 5.4.3.3 with Theorem 2.3.3.23.

**Proposition 5.4.3.3.** Let \(\Delta\) denote the subcategory of \(\Delta\) whose morphisms are given by injective maps \([m] \to [n]\) of linearly ordered finite sets. The functor \(\text{Cut} : \text{N}(\Delta)^{\text{op}} \to \text{Ass}^\circ\) of Construction 4.1.2.5 determines an approximation \(\text{N}(\Delta)^{\text{op}} \to \text{Ass}^\circ_{\text{nu}}\) to the ∞-operad \(\text{Ass}^\circ_{\text{nu}}\).

**Proof.** Combine Proposition 4.1.2.10 with Remark 2.3.3.9.

**Remark 5.4.3.4.** The definition of a nonunital associative algebra makes sense in the more general setting of nonunital planar ∞-operads. We will have no need for this additional generality.

**Definition 5.4.3.5.** Let \(\mathcal{C}^\circ \to \text{N}(\Delta)^{\text{op}}\) be a ∆-monoidal ∞-category, and let \(A \in \Delta\text{Alg}^\text{nu}(\mathcal{C})\) be a nonunital algebra object of \(\mathcal{C}\). Let \(1\) denote the unit object of \(\mathcal{C}\). A map \(u : 1 \to A\) is a right unit if the composition

\[
A \simeq A \otimes 1 \xrightarrow{u} A \otimes A \to A
\]
is homotopic to the identity in \( \mathcal{E} \). Similarly, we will say that \( u \) is a \textit{left unit} if the composition
\[
A \simeq 1 \otimes A \xrightarrow{u} A \otimes A \to A
\]
is homotopic to the identity in \( \mathcal{E} \). We will say that \( u \) is a \textit{quasi-unit} if it is both a left unit and a right unit. We will say that \( A \) is \textit{quasi-unital} if there exists a quasi-unit \( u : 1 \to A \).

**Remark 5.4.3.6.** Let \( A \) be as in Definition 5.4.3.5, and suppose that \( A \) admits a left unit \( u : 1 \to A \) and a right unit \( v : 1 \to A \). Then the composite map
\[
1 \simeq 1 \xrightarrow{u \otimes v} A \otimes A \to A
\]
is homotopic to both \( u \) and \( v \), so that \( u \) and \( v \) are homotopic to each other. It follows that \( A \) is quasi-unital if and only if it admits both a left and a right unit; in this case, the quasi-unit of \( A \) is determined uniquely up to homotopy.

**Definition 5.4.3.7.** Let \( \mathcal{E}^\otimes \to N(\Delta)^{op} \) be a \( \Delta \)-monoidal \( \infty \)-category, and let \( A \in \Delta \text{Alg}^{nu}(\mathcal{E}) \) be a nonunital algebra object of \( \mathcal{E} \), and let \( u : 1 \to A \) be a quasi-unit of \( A \). We will say that a morphism \( f : A \to B \) in \( \Delta \text{Alg}^{nu}(\mathcal{E}) \) is \textit{quasi-unital} if \( f \circ u \) is a quasi-unit for \( B \) (in particular, this implies that \( B \) is quasi-unital). We let \( \Delta \text{Alg}^{nu}(\mathcal{E}) \) denote the subcategory of \( \Delta \text{Alg}^{nu}(\mathcal{E}) \) spanned by the quasi-unital objects of \( \Delta \text{Alg}^{nu}(\mathcal{E}) \) and quasi-unital morphisms between them. We will refer to \( \Delta \text{Alg}^{nu}(\mathcal{E}) \) as the \( \infty \)-\textit{category of quasi-unital algebra morphisms} in \( \mathcal{E} \).

We can now state the main result of this section:

**Theorem 5.4.3.8.** Let \( \mathcal{E}^\otimes \to N(\Delta)^{op} \) be a \( \Delta \)-monoidal \( \infty \)-category. Then the restriction functor
\[
\Delta \text{Alg}(\mathcal{E}) \to \Delta \text{Alg}^{nu}(\mathcal{E})
\]
induces a trivial Kan fibration \( \Delta \text{Alg}(\mathcal{E}) \to \Delta \text{Alg}^{nu}(\mathcal{E}) \).

We will prove Theorem 5.4.3.8 at the end of this section. The basic idea is as follows: if \( A \) is a quasi-unital associative algebra, then \( A \) can be identified with the algebra of (left) \( A \)-module endomorphisms of itself. To make this idea precise, we will need a good theory of nonunital modules over nonunital algebras.

Recall that if \( A \) is a nonunital ring, then a \textit{nonunital left \( A \)-module} is an abelian group \( M \) equipped with a bilinear multiplication map \( A \times M \to M \) which satisfies the associativity formula \( a(bm) = (ab)m \). Note that if \( A \) admits a unit, then this condition does not imply that \( M \) is an \( A \)-module, because it does not imply that the unit element of \( A \) acts by the identity on \( M \). For example, there is a trivial nonunital \( A \)-module structure on any abelian group \( M \), given by the zero map \( A \times M \to M \).

We now adapt the theory of nonunital left modules to the \( \infty \)-categorical context. Let \( \mathcal{LM}^{nu}_{\mathcal{M}} \) denote the \( \infty \)-operad \( \mathcal{LM}^{\otimes}_{\mathcal{N}(\mathcal{M}, \mathcal{N})} \text{Comm}^{nu}_{\mathcal{M}} \). Given a fibration of \( \infty \)-operads \( \mathcal{O}^{\otimes} \to \mathcal{LM}^{\otimes} \), corresponding to an \( \infty \)-category \( M = \mathcal{O}^{\otimes} \) weakly enriched over a planar \( \infty \)-operad \( \mathcal{E}^{\otimes} = \mathcal{O}^{\otimes}_{\mathcal{M}} \), we let \( \text{LMod}^{nu}(M) \) denote the \( \infty \)-category of nonunital \( M \)-module objects of \( M \). We have the following analogue of Proposition 5.4.3.3, which follows immediately from Remarks 4.2.2.8 and 2.3.3.9:

**Proposition 5.4.3.9.** The functor \( \gamma : \Delta^1 \times N(\Delta)^{op} \to \mathcal{LM}^{\otimes} \) of Remark 4.2.2.8 determines an approximation \( \Delta^1 \times N(\Delta)^{op} \to \mathcal{LM}^{\otimes}_{\mathcal{M}} \) to the \( \infty \)-operad \( \mathcal{LM}^{\otimes}_{\mathcal{M}} \).

**Definition 5.4.3.10.** We will say that a morphism in \( \Delta^1 \times N(\Delta)^{op} \) is inert if its image in \( \mathcal{LM}^{\otimes}_{\mathcal{M}} \) is inert. If \( \mathcal{M}^\otimes \to \Delta^1 \times N(\Delta)^{op} \) is a map which exhibits \( M = \mathcal{M}^\otimes \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( \mathcal{M}^\otimes \times \Delta^1 \{1\} \), then we let \( \Delta \text{LMod}^{nu}(\mathcal{E}) \) denote the full subcategory of \( \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\Delta)^{op}, \mathcal{M}^\otimes \) spanned by those functions which carry inert morphisms in \( \Delta^1 N(\Delta)^{op} \) to inert morphisms in \( \mathcal{E}^\otimes \).

Combining Proposition 5.4.3.9 with Theorem 2.3.3.23, we obtain:
Proposition 5.4.3.11. Let $O^\otimes \to LM^\otimes$ be a fibration of $\infty$-operads which exhibits $M = O_m$ as weakly enriched over the $\Delta$-planar $\infty$-operad $O^\otimes = O^\otimes_m$, and let $M^\otimes = O^\otimes \times_{LM^\otimes}(\Delta^1 \times N(\Delta)^{op})$. Then composition with the map $\Delta^1 \times N(\Delta)^{op} \to LM^\otimes_{nu}$ induces an equivalence of $\infty$-categories $LMod^\nu(M) \to \Delta LMod^\nu(M)$.

Remark 5.4.3.12. In the situation of Definition 5.4.3.10, there are evident forgetful functors

$$M \leftarrow \Delta LMod^\nu(M) \to \Delta Alg^\nu(\mathcal{C}).$$

We will generally abuse notation by identifying an object of $\Delta LMod^\nu(M)$ with its image in $M$. If $A$ is a nonunital algebra object of $\mathcal{C}$, we let $\Delta LMod^\nu_A(\mathcal{C})$ denote the fiber product $\Delta LMod^\nu(M) \times_{\Delta Alg^\nu(\mathcal{C})} \{A\}$. If $A \in \Delta Alg(\mathcal{C})$, we will generally abuse notation by writing $\Delta LMod^\nu_A(\mathcal{C})$ for $\Delta LMod^\nu_{\theta(A)}(\mathcal{C})$, where $\theta(A)$ denotes the image of $A$ under the forgetful functor $\theta : \Delta Alg(\mathcal{C}) \to \Delta Alg^\nu(\mathcal{C})$.

Definition 5.4.3.13. Let $M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a coCartesian fibration which exhibits $M = M^\otimes_{(0,[0])}$ as left-tensored over the $\Delta$-monoidal $\infty$-category $\mathcal{C}^\otimes = M^\otimes \times_{\Delta^1} \{1\}$, and let $M \in \Delta LMod^\nu(M)$ be a nonunital module. We will say that $M$ is quasi-unital if the following conditions are satisfied:

1. The image of $M$ in $\Delta Alg^\nu(\mathcal{C})$ is a quasi-unital algebra object $A \in \Delta Alg^\nu(\mathcal{C})$.
2. If $u : 1 \to A$ is a quasi-unit for $A$, then the composite map

$$\psi : M \simeq 1 \otimes M \to A \otimes M \to M$$

is homotopic to the identity (as a morphism in the $\infty$-category $M$).

Remark 5.4.3.14. In view of Remark 5.4.3.6, the condition of Definition 5.4.3.13 does not depend on the choice of a quasi-unit $u : 1 \to A$.

Remark 5.4.3.15. In the situation of Definition 5.4.3.13, the condition that $\psi$ be homotopic to the identity is equivalent to the (apparently weaker) condition that $\psi$ be an equivalence. For suppose that $\psi$ is an equivalence. Since the composition

$$1 \simeq 1 \otimes 1 \stackrel{u \otimes u}{\to} A \otimes A \to A$$

is homotopic to $u$, we conclude that $\psi^2$ is homotopic to $\psi$ (that is, $\psi^2$ and $\psi$ belong to the same connected component of $\text{Map}_M(M,M)$). If $\psi$ is invertible in the homotopy category $\text{h}M$, this forces $\psi$ to be homotopic to the identity.

We have the following counterpart of Theorem 5.4.3.8:

Proposition 5.4.3.16. Let $p : M^\otimes \to \Delta^1 \times N(\Delta)^{op}$ be a coCartesian fibration which exhibits $M = M^\otimes_{(0,[0])}$ as left-tensored over the $\Delta$-monoidal $\infty$-category $\mathcal{C}^\otimes = M^\otimes \times_{\Delta^1} \{1\}$. Fix an object $A \in \Delta Alg(\mathcal{C})$. Then the canonical map

$$\theta : \Delta LMod_A(M) \to \Delta LMod^\nu_A(M)$$

is a trivial Kan fibration.

Proof. It is clear that $\theta$ is a categorical fibration. It will therefore suffice to show that $\theta$ is a categorical equivalence. We may assume without loss of generality that $M^\otimes = (\Delta^1 \times N(\Delta)^{op}) \times_{LM^\otimes} M^\otimes$ for some coCartesian fibration of $\infty$-operads $M^\otimes \to LM^\otimes$. Let $M^\otimes \to \mathcal{C}^\otimes$ be defined as in Notation 4.2.2.16, and let $N = N(\Delta)^{op} \times_{\mathcal{C}^\otimes} M^\otimes$ where $N(\Delta)^{op}$ maps to $\mathcal{C}^\otimes$ via the algebra object $A$. Let $q : N \to N(\Delta)^{op}$ be the canonical map, so that $q$ is a locally coCartesian fibration (Lemma 4.2.2.19).

We define a subcategory $J \subseteq [1] \times \Delta^{op}$ as follows:

- Every object of $[1] \times \Delta^{op}$ belongs to $J$.
- A morphism $\alpha : (i,[m]) \to (j,[n])$ in $[1] \times \Delta^{op}$ belongs to $J$ if and only if either $i = 0$ or the map $[n] \to [m]$ is injective.
CHAPTER 5. LITTLE CUBES AND FACTORIZABLE SHEAVES

For $i = 0, 1$, we let $J_i$ denote the full subcategory of $J$ spanned by the objects $\{(i,[n])\}_{n \geq 0}$, so that $J_0 \simeq \Delta^\text{op}$ and $J_1 \simeq \Delta_1^\text{op}$. There is an evident forgetful functor $J \to \Delta^\text{op}$. We observe that $\Delta \text{Mod}_A(M)$ and $\Delta_1 \text{Mod}_A^\text{nu}(M)$ can be identified with full subcategories of $\text{Fun}_{\Delta^\text{op}}(N(J_0), N)$ and $\text{Fun}_{\Delta_1^\text{op}}(N(J_0 1), N)$, respectively.

Let $X$ denote the full subcategory of $\text{Fun}_{\Delta^\text{op}}(N(J), N)$ spanned by those functors $F$ with the following properties:

(i) The restriction $F_0 = F|N(J_0)$ belongs to $\Delta \text{Mod}_A(M)$.

(ii) The functor $F$ is a $q$-left Kan extension of $F_-$.

Note that conditions (i) and (ii) immediately imply:

(iii) The restriction $F_1 = F|N(J_1)$ belongs to $\Delta_1 \text{Mod}_A^\text{nu}(M)$.

Conversely, conditions (ii) and (iii) imply (i) (since every inert morphism in $N(\Delta)^{op}$ belongs to $N(\Delta_1)^{op}$).

The map $\theta$ factors as a composition

$$\Delta \text{Mod}_A(M) \overset{\theta'}\to X \overset{\theta''}\to \Delta_1 \text{Mod}_A^\text{nu}(M).$$

Proposition T.4.3.2.15 implies that $\theta'$ is the section of a trivial Kan fibration $X \to \Delta \text{Mod}_A(M)$, and therefore a categorical equivalence. We will complete the proof by showing that $\theta''$ is a trivial Kan fibration. According to Proposition T.4.3.2.15, it will suffice to prove:

(a) For every $F_1 \in \Delta_1 \text{Mod}_A^\text{nu}(M) \subseteq \text{Fun}_{\Delta_1^\text{op}}(N(J_1), N)$, there exists a functor $F \in \text{Fun}_{\Delta^\text{op}}(N(J), N)$ which is a $p$-right Kan extension of $F_1$.

(b) If $F \in \text{Fun}_{\Delta^\text{op}}(N(J), N)$ is a functor such that $F_1 = F|N(J_1)$ belongs to $\Delta_1 \text{Mod}_A^\text{nu}(M)$, then $F \in X$ if and only if $F$ is a $p$-right Kan extension of $F_1$.

We begin by proving (a). Fix a functor $F_1 \in \Delta_1 \text{Mod}_A^\text{nu}(M) \subseteq \text{Fun}_{\Delta_1^\text{op}}(N(J_1), N)$ and an object $E = (0,[n]) \in J_0$. Let $\beta = J_1 \times_J J_{E/}$. According to Lemma T.4.3.2.13, it will suffice to show that $f = F_1|N(\beta)$ can be extended to a $q$-limit diagram $N(\beta)q \to N$ (compatible with the evident map $N(\beta)q \to N(\Delta)^{op}$).

Let $J_0$ denote the full subcategory of $J$ spanned by those maps $(0,[n]) \to (1,[m])$ for which the image of the underlying map $[m] \to [n]$ contains $n$. We claim that the inclusion $N(J_0) \subseteq N(\beta)$ is right cofinal. In view of Theorem T.4.1.3.1, it will suffice to show that, for every morphism $E \to E' = (1,[m])$ in $J$, the category $\mathcal{Z} = J_0 \times_J E/ \times_{J_{E/}} J_{E'/E'}$ has a weakly contractible nerve. Let $\gamma : [m] \to [n]$ be the underlying map of linearly ordered sets. If $\gamma(m) = n$ then $\mathcal{Z}$ has a final object and there is nothing to prove. Assume therefore that $\gamma(m) < n$. Unwinding the definitions, we can identify $\mathcal{Z}$ with a product of categories $\{\mathcal{E}_{i}^{op}\}_{0 \leq i \leq n}$, where

$$\mathcal{E}_i \simeq \begin{cases} (\Delta_{s, +})^\gamma_{i-1(i)}/ \Delta_{s} & \text{if } i < n \\ \Delta_{s} & \text{if } i = n. \end{cases}$$

The categories $\mathcal{E}_i$ have initial objects for $i < n$, and $\mathcal{E}_n$ has weakly contractible nerve (because the inclusion $N(\Delta_s) \subseteq N(\Delta)$ is right cofinal (Lemma T.5.5.8.4), right cofinal maps are weak homotopy equivalences (Proposition T.4.1.1.3), and $N(\Delta)$ is weakly contractible (Lemma T.5.5.8.4 and Proposition T.5.5.8.7)). It follows that $N(\mathcal{Z}) \simeq \prod_{0 \leq i \leq n} N(\mathcal{E}_i)^{op}$ is likewise weakly contractible. We are therefore reduced to proving:

(a') There exists a $q$-limit diagram $\mathcal{E} : N(J_0)^q \to N$ rendering the following diagram commutative:

$$\begin{array}{ccc} N(J_0) & \xrightarrow{g} & N \\ \downarrow \mathcal{E} \uparrow & \mathcal{E} & \downarrow \mathcal{E} \uparrow \\ N(J_0)^q & \xrightarrow{p} & N(\Delta)^{op}, \end{array}$$

where $g$ is given by the restriction of $F_1$. 
5.4. LITTLE CUBES AND MANIFOLD TOPOLOGY

We now observe that, for every morphism \( \alpha : [m] \to [n] \) in \( \Delta \) for which \( \alpha(m) = n \) classifying a map \( \Delta^1 \to N(\Delta)^{op} \), the pullback \( N \times_{N(\Delta)^{op}} \Delta^1 \) is equivalent to a product \( M \times \Delta^1 \). It follows that for every object \( N \in N([m]) \), there exists a locally \( q \)-Cartesian morphism \( \overline{\alpha} : N' \to N \) in \( N \) covering \( \alpha \). Remark 4.2.2.22 implies that \( \overline{\alpha} \) is \( q \)-Cartesian.

Let \( h_1 : N(\Delta)^{op} \to N(\Delta)^{op} \) denote the composition \( N(\Delta)^{op} \to N(\Delta)^{op} \to N(\Delta)^{op} \) from \( h_1 = h_1(0) \times N(\Delta)^{op} \) to \( h_1 \), where \( h_1 \) is the constant functor taking the value \([n]\). For each object \( x \in N(\Delta)^{op} \), the restriction of \( h \) to \( \Delta^1 \times \{x\} \) classifies a morphism \( \alpha : [m] \to [n] \) satisfying \( \alpha(m) = n \). It follows that we can lift \( h(\Delta^1 \times \{0\}) \) to a \( p \)-Cartesian transformation \( h : g' \to g \). Using Proposition T.4.3.1.9, we are reduced to proving that the diagram

\[
\begin{array}{ccc}
M & \xrightarrow{g'} & C \\
\downarrow & & \downarrow \\
N(\Delta)^{op} & \xrightarrow{\overline{\alpha}} & C^{op},
\end{array}
\]

we conclude that \( \overline{\alpha} \) is a \( q \)-limit diagram. Since \( q \) is a pullback of \( g' \), we deduce that \( \overline{\alpha} \) is a \( q \)-limit diagram, as desired. This completes the proof of (a). Moreover, the proof shows that an arbitrary extension \( F \) of \( F_1 \) is a \( q \)-right Kan extension at \([0, [n]]\) if and only if, for some \( \gamma : [m] \to [n] \) in \( \Delta \) with \( \gamma(m) = n \), the map \( F(0, [n]) \to F(1, [m]) \) is locally \( q \)-Cartesian; moreover, this condition is independent of the choice of \( \gamma \). In particular, we can take \( \gamma = id_{[n]} \) to conclude that \( F \) is a \( q \)-right Kan extension of \( F_1 \) if and only if \( F \) satisfies condition (ii), which proves (b).

We now return to Theorem 5.4.3.8. Before giving the proof, let us sketch the main idea. Suppose that \( A \) is a nonunital ring, and we wish to promote \( A \) to an associative ring. Let \( M = A \), regarded as a (nonunital) right module over itself. Left multiplication induces a homomorphism of nonunital algebras \( \phi : A \to \text{Hom}_A(M, M) \). If \( A \) admits a left unit 1, then \( A \) is freely generated by 1 as a right \( A \)-module, so that evaluation at 1 induces an isomorphism \( \text{Hom}_A(M, M) \cong M \). Under this isomorphism, \( \phi \) corresponds to the map \( a \mapsto a1 \). If the element 1 \( \in A \) is also a right unit, then \( \phi \) is an isomorphism. On the other hand, \( \text{End}_A(M, M) \) is manifestly an associative ring. To translate this sketch into the setting of higher category theory, we will need the following lemma, which will be proven at the end of this section:

**Lemma 5.4.3.17.** Let \( C \) be a \( \Delta \)-monoidal \( \infty \)-category, and let \( A \in \Delta \text{Alg}_M^{nu} (C) \). There exists an \( \infty \)-category \( M \) which is left-tensored over \( C \) and an object \( M \in \Delta \text{LMod}_A^{nu} (M) \) for which the underlying map \( A \otimes M \to M \) exhibits \( A \) as a classifying object for morphisms from \( M \) to \( M \).

We will also need some nonunital analogues of the results of §5.7.2.

**Lemma 5.4.3.18.** Let \( p : M^{op} \to \Delta \times N(\Delta)^{op} \) be a map which exhibits \( M = N^{op}_{[0]} \) as weakly enriched over the \( \Delta \)-planar \( \infty \)-operad \( C^{op} = M^{op} \times \Delta \{1\} \). Let \( s : N(\Delta)^{op} \to N(\Delta)^{op} \) be the functor given on objects by \([n] \mapsto ([n], 0, n) \). Then, for each object \( M \in M \), composition with \( s \) induces a categorical equivalence

\[
\theta : \Delta \text{Alg}_M^{nu} (C^{op}([M])) \to \Delta \text{LMod}_M^{nu} (M) \times_M \{M\}.
\]
Proof. The proof is essentially identical to that of Theorem 4.7.2.34. Let \( \mathrm{Po}_s = \mathrm{Po} \times \Delta \), and let \( \mathcal{X} \subseteq \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\Delta^1 \times N(\mathrm{Po}_s)^{op}, \mathbb{M}^{op}) \) be the full subcategory spanned by those functors \( F \) satisfying the following conditions:

(a) If \( 0 \leq i \leq i' \leq j \leq n \), then the map \( F(0, [n], i, j) \rightarrow F(0, [n], i', j) \) is inert.
(b) If \( 0 \leq i \leq i' \leq j' \leq n \), then the map \( F(1, [n], i, j) \rightarrow F(1, [n], i', j') \) is inert.
(c) For \( 0 \leq i \leq j \leq n \), the map \( F(0, [n], i, j) \rightarrow F(1, [n], i, j) \) is inert.
(d) If \( \alpha : [m] \rightarrow [n] \) is an inert morphism in \( \Delta \), then \( F(0, [n], \alpha(i), \alpha(j)) \rightarrow F(0, [m], i, j) \) is an equivalence in \( \mathbb{M}^{op} \).

Note that conditions (a) and (d) imply the following:

(a') For every inert morphism \( \alpha : [m] \rightarrow [n] \) in \( \Delta \), satisfying \( \alpha(m) = n \), the induced map \( F(0, [n], 0, n) \rightarrow F(0, [m], 0, m) \) is inert.

Similarly, (b) and (d) imply:

(b') For every inert morphism \( \alpha : [m] \rightarrow [n] \) in \( \Delta \), the induced map \( F(1, [n], 0, n) \rightarrow F(1, [m], 0, m) \) is inert.

Finally, (c) and (d) imply:

(d') If \( \alpha : [m] \rightarrow [n] \) is an inert morphism in \( \Delta \), then \( F(1, [n], \alpha(i), \alpha(j)) \rightarrow F(1, [m], i, j) \) is an equivalence in \( \mathbb{M}^{op} \).

It follows that composition with \( s \) induces a forgetful functor \( \theta' : \mathcal{X} \rightarrow \Delta \text{LMod}^{nu}(\mathbb{M}) \). Let \( \mathrm{Po}'_s = \mathrm{Po}' \cap \mathrm{Po}_s \), and let \( \mathcal{X}_0 \subseteq \text{Fun}(\mathrm{Po}'_s)^{op}, \mathbb{M} \) be the full subcategory spanned by those functors which carry each morphism in \( \mathrm{N}(\mathrm{Po}'_s)^{op} \) to an equivalence in \( \mathbb{M} \). Let \( \mathcal{M} \in \mathcal{X}_0 \) be the constant functor taking the value \( M \in \mathbb{M} \). Unwinding the definitions, we have a canonical isomorphism \( \Delta \text{Alg}^{nu}(\mathcal{C}^\dagger(M)) \simeq \mathcal{X} \times \mathcal{X}_0 \mathcal{M} \). In other words, we can identify \( \theta' \) with the map between vertical fibers determined by the diagram

\[
\begin{array}{ccc}
\mathcal{X} & \xrightarrow{\phi} & \Delta \text{LMod}^{nu}(\mathbb{M}) \\
\downarrow & & \downarrow \\
\mathcal{X}_0 & \xrightarrow{\phi_0} & \mathbb{M}.
\end{array}
\]

It will therefore suffice to show that the functors \( \phi \) and \( \phi_0 \) are categorical equivalences. The map \( \phi_0 \) is an equivalence since \( \mathrm{N}(\mathrm{Po}'_s)^{op} \) is weakly contractible (it has a final object, given by \( ([0], 0, 0) \)). It will therefore suffice to show that \( \phi \) is a categorical equivalence. Let \( \mathcal{X}' \) be the full subcategory of \( \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\{0\} \times N(\mathrm{Po}_s)^{op}, \mathbb{M}^{op}) \) spanned by those functors \( F \) which satisfy \( (a') \), \( (b') \), \( (d') \), and the following weaker version of (c):

(c') For \( n \geq 0 \), the map \( F(0, [n], 0, n) \rightarrow F(1, [n], 0, n) \) is inert.

A functor \( F \in \text{Fun}_{\Delta^1 \times N(\Delta)^{op}}(\{0\} \times N(\mathrm{Po}_s)^{op}, \mathbb{M}^{op}) \) belongs to \( \mathcal{X}' \) if and only if \( F_0 = F(\Delta^1 \times N(\Delta)^{op}) \) determines an object of \( \Delta \text{LMod}^{nu}(\mathbb{M}) \) and \( F \) is a \( p \)-right Kan extension of \( F_0 \). Then \( \mathcal{X}' \) is a full subcategory of \( \mathcal{X} \) and Proposition T.4.3.2.15 guarantees that the restriction map \( \phi|_{\mathcal{X}'} \) is a trivial Kan fibration. We will complete the proof by showing that \( \mathcal{X} = \mathcal{X}' \). In other words, we will show that a functor \( F \in \mathcal{X}' \) also satisfies conditions \( (a) \), \( (b) \), and \( (c) \). To prove \( (a) \), consider \( 0 \leq i \leq i' \leq j \leq n \). Condition \( (a) \) guarantees that the induced map \( F(0, [n], i, j) \rightarrow F(0, [n], i', j) \) is equivalent to the map \( F([j - i], 0, j - i) \rightarrow F([j - i], 0, j - i') \) and is therefore inert by \( (a') \). To prove \( (b) \), we assume that \( 0 \leq i \leq i' \leq j' \leq j \leq n \) and note that \( (d') \) implies that \( F(0, [n], i, j) \rightarrow F(0, [n], i', j) \) is equivalent to the map \( LF([j - i], 0, j - i) \rightarrow LF([j' - i'], 0, j' - i') \).
which is inert by (b'). It remains to verify (c). Fix $0 \leq i \leq j \leq n$; we wish to show that the map $u : F(0, [n], i, j) \to F(1, [n], i, j)$ is inert. Using (b), we are reduced to proving that the composite map $F(0, [n], i, j) \to F(1, [n], i, j) \simeq F(1, [j - i], 0, j - i)$ is inert. This map factors as a composition

$$F(0, [n], i, j) \xrightarrow{u'} F(0, [j - i], 0, j - i) \xrightarrow{u''} F(1, [j - i], 0, j - i)$$

where $u'$ is an equivalence by (a) and $u''$ is inert by virtue of (c').

**Lemma 5.4.3.19.** Let $M$ be an $\infty$-category weakly enriched over a $\Delta$-planar $\infty$-operad $C^\otimes$. For each object $M \in M$, the forgetful functor $\theta : C^+[M] \to C^\otimes$ induces a right fibration $\Delta Alg^{nu}(C^+[M]) \to \Delta Alg^{nu}(C)$.

**Proof.** Combine Lemmas 4.7.2.36 and 4.7.2.37.

**Lemma 5.4.3.20.** Let $C$ be a $\Delta$-monoidal $\infty$-category, $M$ an $\infty$-category which is left-tensored over $C$, and $M \in M$ an object. Then the forgetful functor

$$\Delta LMod^{nu}(M) \times_M M \to \Delta Alg^{nu}(C)$$

is a right fibration.

**Proof.** Combine Lemma 5.4.3.19 and 5.4.3.18.

**Lemma 5.4.3.21.** Let $M$ be an $\infty$-category left-tensored over a $\Delta$-monoidal $\infty$-category $C^\otimes$. Assume that the $\infty$-category $C^+[M]$ has a final object $A$. Then:

1. The object $A$ can be promoted to an object of $\Delta Alg^{nu}(C^+[M])$ in an essentially unique way. We will abuse notation by denoting this object also by $A$.

Let $\theta : \Delta Alg^{nu}(C^+[M]) \to \Delta Alg^{nu}(C)$ be the forgetful functor. Then:

2. There is a canonical equivalence of $\infty$-categories $\Delta Alg^{nu}(C)/\theta(A) \simeq \Delta LMod^{nu}(M) \times_M M$.

**Proof.** Proposition 4.7.2.30 implies that the forgetful functor $C[M]^\otimes \to N(\Delta)^{op}$ exhibits $C[M]^\otimes$ as a $\Delta$-monoidal $\infty$-category, so that $C[M]^\otimes \simeq \O^{\otimes} \times_{Ass^{op}} N(\Delta)^{op}$ for some coCartesian fibration of $\infty$-operads $O^\otimes \to Ass^{op}$. Combining Corollary 3.2.5 with Proposition 5.4.3.2, we deduce that $A$ can be lifted to an object of $\Delta Alg^{nu}(C[M])$, and that any such lifting is a final object of $\Delta Alg(C[M])$ (and therefore uniquely determines up to equivalence. Since the map $\Delta Alg(C^+[M]) \to \Delta Alg(C[M])$ is a trivial Kan fibration; we may lift $A$ to a final object of $\Delta Alg(C^+[M])$, which we will also denote by $A$. This proves (1). We have a diagram of maps

$$\Delta Alg^{nu}(C)/\theta(A) \gets \Delta Alg^{nu}(C^+[M])/A \to \Delta Alg^{nu}(C^+[M]) \to \Delta LMod^{nu}(M) \times_M M$$

which are equivalences of $\infty$-categories by virtue of Lemmas 5.4.3.19 and 5.4.3.18.

**Corollary 5.4.3.22.** Let $M$ be an $\infty$-category left-tensored over a $\Delta$-monoidal $\infty$-category $C^\otimes$. Let $M \in \Delta LMod^{nu}(M)$ be a nonunital left module object having images $M \in M$ and $A \in \Delta Alg^{nu}(C)$. Suppose that the multiplication map $A \otimes M \to M$ exhibits $A$ as a classifying object for endomorphisms of $M$. Then, for every algebra object $B \in \Delta Alg^{nu}(C)$, we have a canonical isomorphism $Map_{\Delta Alg^{nu}(C)}(B, A) \simeq \Delta LMod^{nu}(M) \times_M M$ in the homotopy category $\mathcal{M}$ of spaces.

**Proof of Theorem 5.4.3.8.** The restriction functor $\theta : \Delta Alg(C) \to \Delta Alg^{nu}(C)$ is evidently a categorical fibration. It will therefore suffice to show that $\theta$ is a categorical equivalence. We first show that $\theta$ is essentially surjective. Let $A_0$ be a quasi-unital algebra object of $C$. According to Lemma 5.4.3.17, we can find an $\infty$-category $M$ which is left-tensored over $C$ and a quasi-unital module $M_0 \in \Delta LMod^{nu}(M)$.
which exhibits $A_0$ as a classifying object for morphisms from $M$ to $M$; here we let $M$ denote the image of $\overline{M}_0$ under the forgetful functor $\Delta \text{LMod}^{\text{nu}}(M) \to M$. We have a commutative diagram

$$
\begin{array}{ccc}
\Delta \text{LMod}(M) \times_M \{M\} & \longrightarrow & \Delta \text{Alg}(\mathcal{C}^+[M]) \\
\downarrow & & \downarrow \phi' \\
\Delta \text{LMod}^{\text{nu}}(M) \times_M \{M\} & \longrightarrow & \Delta \text{Alg}^{\text{nu}}(\mathcal{C}^+[M]) \\
\phi & & \phi
\end{array}
$$

Let $\overline{A}_0$ be the image of $\overline{M}_0$ in $\Delta \text{Alg}^{\text{nu}}(\mathcal{C}^+[M])$. To prove that $A_0$ belongs to the essential image of $\phi'$, we will suffice to show that $\overline{A}_0$ belongs to the essential image of $\phi'$.

Let $C \in \mathcal{C}^+[M]$ denote the image of $\overline{A}_0$. By assumption, $C$ is a final object of $\mathcal{C}^+[M]$. Using Corollary 3.2.2.5 and Proposition 5.4.3.2, we deduce that $\overline{A}_0$ is a final object of $\Delta \text{Alg}^{\text{nu}}(\mathcal{C}^+[M])$. On the other hand, Corollary 3.2.2.5 and Proposition 4.1.2.15 imply that $\text{Alg}(\mathcal{C}^+[M])$ has a final object $\overline{A}$. Using Corollary 3.2.2.5 and Proposition 5.4.3.2 again, we deduce that $\phi'(\overline{A})$ is a final object of $\Delta \text{Alg}^{\text{nu}}(\mathcal{C}^+[M])$ and therefore equivalent to $\overline{A}_0$, which proves that $\overline{A}_0$ belongs to the essential image of $\phi'$.

We now prove that $\phi'$ is fully faithful. Fix objects $A, B \in \Delta \text{Alg}(\mathcal{C})$, and set $A_0 = \phi(A) \in \Delta \text{Alg}^{\text{nu}}(\mathcal{C})$, $B_0 = \phi(B) \in \Delta \text{Alg}^{\text{nu}}(\mathcal{C})$. We wish to prove that the map $\text{Map}_{\Delta \text{Alg}(\mathcal{C})}(B, A) \to \text{Map}_{\Delta \text{Alg}^{\text{nu}}(\mathcal{C})}(B_0, A_0)$ is a homotopy equivalence. Use Lemma 5.4.3.17 to choose $\overline{M}_0 \in \Delta \text{LMod}^{\text{nu}}_{A_0}(M)$ as above. Consider the diagram

$$
\begin{array}{ccc}
\Delta \text{LMod}(M) & \longrightarrow & \Delta \text{LMod}(M) \times_M \{M\} \\
\downarrow & & \downarrow \phi' \\
\Delta \text{LMod}^{\text{nu}}(M) & \longrightarrow & \Delta \text{LMod}^{\text{nu}}_{A_0}(M) \times_M \{M\} \\
\phi & & \phi
\end{array}
$$

The left square is a pullback, and the left vertical map is a trivial Kan fibration (Proposition 5.4.3.16). The horizontal maps on the right are both categorical equivalences (Theorem 4.7.2.34 and Lemma 5.4.3.18). Using the two-out-of-three property, we deduce that $\phi'$ is a categorical equivalence. Since $\psi$ is also a categorical fibration, it is a trivial Kan fibration; we may therefore choose $\overline{M} \in \Delta \text{LMod}(M)$ lifting $\overline{M}_0$.

According to Corollary 4.7.2.41 and Lemma 5.4.3.22, we have canonical homotopy equivalences

$$
\phi : \text{Map}_{\Delta \text{Alg}(\mathcal{C})}(B, A) \simeq \Delta \text{LMod}(M) \times_M \{M\}
$$

$$
\phi^{\text{nu}} : \text{Map}_{\Delta \text{Alg}^{\text{nu}}(\mathcal{C})}(B_0, A_0) \simeq \Delta \text{LMod}^{\text{nu}}_{B_0}(M) \times_M \{M\}.
$$

Let $f : B_0 \to A_0$ be a map of nonunital algebras, and let $\overline{B}_0$ be the corresponding object of $\Delta \text{LMod}^{\text{nu}}_{B_0}(M)$. Let $u : 1 \to B$ be the unit map for the algebra $B$. Then $f$ is quasi-unital if and only if the composition $u : 1 \to B \to A$ is homotopic to the unit of $A$; here we abuse notation by identifying $A$ and $B$ with their images in $\mathcal{C}$. Since $A$ is a classifying object for morphisms from $M$ to itself, we can identify $u$ with the induced map $u' : 1 \otimes M \to M$, so that $f$ is quasi-unital if and only if $u'$ is homotopic to the identity, which is equivalent to the condition that $\overline{B}_0$ be quasi-unital. It follows that $\phi^{\text{nu}}$ restricts to a homotopy equivalence

$$
\phi^{\text{nu}} : \text{Map}_{\Delta \text{Alg}^{\text{nu}}(\mathcal{C})}(B_0, A_0) \simeq \Delta \text{LMod}^{\text{nu}}_{B_0}(M) \times_M \{M\}.
$$

We wish to prove that $\phi$ induces a homotopy equivalence $\text{Map}_{\Delta \text{Alg}(\mathcal{C})}(B, A) \to \text{Map}_{\Delta \text{Alg}^{\text{nu}}(\mathcal{C})}(B_0, A_0)$. In view of the above identifications, it will suffice to show that the restriction map

$$
g : \Delta \text{LMod}(M) \times_M \{M\} \to \Delta \text{LMod}^{\text{nu}}_{B_0}(M) \times_M \{M\}
$$

is a homotopy equivalence. Proposition 5.4.3.16 implies that $g$ is a trivial Kan fibration.

We now turn to the proof of Lemma 5.4.3.17. The idea is to define $M$ to be the $\infty$-category of nonunital right $A$-modules in $\mathcal{C}$, and $M \in M$ to be $A$ itself, regarded as a right $A$-module.
5.4. LITTLE CUBES AND MANIFOLD TOPOLOGY

Proof of Lemma 5.4.3.17. We may assume without loss of generality that $\mathcal{C}^\otimes = \mathcal{C}^\otimes \times_{\text{Ass}} N(\Delta)^{op}$ for some monoidal ∞-category $\mathcal{C}^\otimes$, and that $A$ is the image of an object of $\text{Alg}^{nu}(\mathcal{C})$ (which we will also denote by $A$). Let us regard $\mathcal{C}$ as bitensored over itself. Using a variant on the constructions described in §4.3.2, we can view the ∞-category $\mathcal{M} = \text{RMod}^{nu}(\mathcal{C})$ of nonunital right $A$-modules as an ∞-category which is left-tensored over $\mathcal{C}^\otimes$, and therefore left-tensored over the Δ-monoidal ∞-category $\mathcal{C}^\otimes$. Let $M \in \mathcal{M}$ be the object corresponding to $A$ (regarded as a nonunital right module over itself in the obvious way), so that $M$ inherits an evident (nonunital) left action of $A$. We claim that the action map $\theta : A \otimes M \to M$ exhibits $A$ as a morphism object $\text{Mor}_\mathcal{M}(M,M)$. To prove this, it suffices to show that for every object $C \in \mathcal{C}$, composition with $\theta$ induces a homotopy equivalence $\text{Map}_\mathcal{C}(C,A) \to \text{Map}_\mathcal{M}(C \otimes M,M)$.

We must show that for every Kan complex $K$, $\theta$ induces a bijection

$$[K, \text{Map}_\mathcal{C}(C,A)] \to [K, \text{Map}_\mathcal{M}(C \otimes M,M)];$$

here $[K,X]$ denotes the set of maps from $K$ to $X$ in the homotopy category $\mathcal{H}$ of spaces. Replacing $\mathcal{C}$ by $\text{Fun}(K,\mathcal{C})$ and $A$ by the nonunital algebra $A' \in \text{Alg}^{nu}(\text{Fun}(K,\mathcal{C})) \simeq \text{Fun}(K,\text{Alg}^{nu}(\mathcal{C}))$ corresponding to the constant map $K \to \{A\} \subseteq \text{Alg}^{nu}(\mathcal{C})$, we can reduce to the case where $K = \Delta^0$. In other words, it will suffice to show composition with $\theta$ induces a bijection of sets $q : \pi_0 \text{Map}_\mathcal{C}(C,A) \to \pi_0 \text{Map}_\mathcal{M}(C \otimes M,M)$.

Our next step is to construct an inverse to $q$. Let $u : 1 \to A$ be a quasi-unit. Let $\phi : C \otimes M \to M$ be an arbitrary morphism in $\mathcal{M}$. Then $\phi$ determines a map $C \otimes A \to A$ in $\mathcal{C}$. Let $q'(\phi)$ denote the composition

$$C \simeq C \otimes 1 \xrightarrow{u} C \otimes A \to A.$$

We may view $q'$ as a map of sets from $\pi_0 \text{Map}_\mathcal{M}(C \otimes M,M)$ to $\pi_0 \text{Map}_\mathcal{C}(C,A)$. The composition $q' \circ q : \pi_0 \text{Map}_\mathcal{C}(C,A) \to \pi_0 \text{Map}_\mathcal{C}(C,A)$ is induced by the map $r_u : A \to A$ given by right multiplication by $u$.

Since $u$ is a right unit of $A$, we deduce that $q' \circ q$ is the identity. In particular, $q$ is injective.

To complete the proof, it will suffice to show that $q$ is surjective. According to Theorem 4.7.2.34, if $C$ is an object of $\mathcal{C}$, then giving a map $\phi : C \otimes M \to M$ in $\mathcal{M}$ is equivalent to lifting $C$ to an object $\tilde{C} \in \mathcal{C}^+[M]$. In particular, the left action of $A$ on $M$ gives rise to a canonical element $\tilde{A} \in \mathcal{C}^+[M]$. Then $\phi$ belongs to the image of $q$ if and only if there exists a map $\tilde{C} \to \tilde{A}$ in $\mathcal{C}^+[M]$. Consequently, the surjectivity of $q$ is equivalent to the following assertion:

(*) For every object $\tilde{C} \in \mathcal{C}^+[M]$, there exists a morphism $\tilde{C} \to \tilde{A}$ in $\mathcal{C}[M]$.

Proposition 4.7.2.39 asserts that the forgetful functor $\mathcal{C}^+[M] \to \mathcal{C}$ is a right fibration. Consequently, the quasi-unit $u : 1 \to A$ can be lifted to a map $\tilde{u} : E \to \tilde{A}$ in $\mathcal{C}^+[M]$. Since $u$ is a left unit of $A$, the object $E$ classifies a map $v : 1 \otimes M \to M$ which is an equivalence in $\mathcal{C}$, so that $v$ is an equivalence in $\mathcal{M}$. It follows from Remark 4.7.2.31 that $E$ is an invertible object of $\mathcal{C}^+[M]$ (see Remark 4.1.1.19), so that the functor $\tilde{C} \to \tilde{C} \otimes E$ is an equivalence from $\mathcal{C}^+[M]$ to itself. Consequently, condition (*) is equivalent to:

(**) For every object $\tilde{C} \in \mathcal{C}^+[M]$, there exists a morphism $\tilde{C} \otimes E \to \tilde{A}$ in $\mathcal{C}^+[M]$.

In view of the existence of $\tilde{u} : E \to \tilde{A}$, it will suffice to prove the following slightly stronger assertion:

(**') For every object $\tilde{C} \in \mathcal{C}^+[M]$, there exists a morphism $\tilde{C} \otimes \tilde{A} \to \tilde{A}$ in $\mathcal{C}^+[M]$.

Applying Theorem 4.7.2.34 again, we see that (**') is equivalent to the following assertion: for every map $\phi : C \otimes M \to M$, there exists a commutative diagram

$$
\begin{array}{ccc}
C \otimes A \otimes M & \longrightarrow & C \otimes M \\
\downarrow & & \downarrow \phi \\
A \otimes M & \longrightarrow & M;
\end{array}
$$

in $\mathcal{M}$, where the horizontal arrows are given by the canonical action of $A$ on $M$. This is a straightforward consequence of the constructions of $\mathcal{M}$ and $M$. 

\qed
5.4.4 Nonunital $\mathbb{E}_k$-Algebras

Let $A$ be an abelian group equipped with a commutative and associative multiplication $m : A \otimes A \rightarrow A$. A unit for the multiplication $m$ is an element $1 \in A$ such that $1a = a$ for each $a \in A$. If there exists a unit for $A$, then that unit is unique and $A$ is a commutative ring (with unit). Our goal in this section is to prove an analogous result, where the category of abelian groups is replaced by an arbitrary symmetric monoidal $\infty$-category $\mathcal{C}$ (Corollary 5.4.4.7). We begin with a discussion of nonunital algebras in general.

**Definition 5.4.4.1.** Let $\text{Surj}$ denote the subcategory of $\mathcal{F}_{\text{in}*}$ containing all objects of $\mathcal{F}_{\text{in}*}$, such that a morphism $\alpha : (m) \rightarrow (n)$ belongs to $\text{Surj}$ if and only if it is surjective. If $\mathcal{O}_\circ$ is an $\infty$-operad, we let $\mathcal{O}_\circ^{nu}$ denote the fiber product $\mathcal{O}_\circ^{\otimes} \times_{N(\mathcal{F}_{\text{in}*})} N(\text{Surj})$. Given a fibration of $\infty$-operads $\mathcal{O}_\circ^{\otimes} \rightarrow D^{\otimes}$ and a map of $\infty$-operads $\mathcal{O}_\circ^{\otimes} \rightarrow \mathcal{D}_\circ^{\otimes}$, we let $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{D}_\circ^{\otimes}}(\mathcal{C})$ denote the $\infty$-category $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}(\mathcal{D})(\mathcal{C})$. We will refer to $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{D}_\circ^{\otimes}}(\mathcal{C})$ as the $\infty$-category of nonunital $\mathcal{O}_\circ$-algebra objects of $\mathcal{C}$. In the special case where $D^{\otimes} = \mathcal{O}_\circ^{\otimes}$, we will denote $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}(\mathcal{D})(\mathcal{C})$ by $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$. In the special case where $D = N(\mathcal{F}_{\text{in}*})$, we will denote $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$ by $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$.

Our goal is to show that if $\mathcal{O}_\circ^{\otimes}$ is a little $k$-cubes operad $\mathbb{E}_k$ for some $k \geq 1$, then the $\infty$-category $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$ of nonunital $\mathcal{O}_\circ$-algebra objects of $\mathcal{C}$ is not very different from the $\infty$-category $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$ of unital $\mathcal{O}_\circ$-algebra objects of $\mathcal{C}$. More precisely, we will show that the restriction functor $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C}) \rightarrow \mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$ induces an equivalence of $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$ onto a subcategory $\mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C}) \subseteq \mathcal{A}_{\mathcal{O}_\circ^{\otimes}}^{\mathcal{O}_\circ^{\otimes}}(\mathcal{C})$ whose objects are required to admit units up to homotopy and whose morphisms are required to preserve those units (see Definition 5.4.4.2 below).

We now formulate a generalization of Theorem 5.4.3.8.

**Definition 5.4.4.2.** Let $q : \mathcal{C}_\circ^{\otimes} \rightarrow \mathbb{E}_k^{\otimes}$ be a coCartesian fibration of $\infty$-operads. If $k = 1$, then the composite map $q^{\otimes} \rightarrow \mathbb{E}_k^{\otimes} \rightarrow \mathbb{A}_{\mathcal{C}}^{\otimes}$ exhibits $\mathcal{C}_\circ^{\otimes}$ as a monoidal $\infty$-category. We let $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ denote the subcategory of nonunital $\mathcal{E}_k$-algebra objects $\mathcal{C}$ isomorphic to $\mathcal{E}_k$, as in Definition 5.4.3.5. Then $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ admits a quasi-unit $u$ if and only if it admits a quasi-unit $u$; in this case, $u$ is determined uniquely up to homotopy. A morphism $f : A \rightarrow B$ belongs to $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ if and only if $u$ admits a quasi-unit $q : 1 \rightarrow A$ and the composite map $f \circ u$ is a quasi-unit for $B$.

**Remark 5.4.4.3.** We can make Definition 5.4.4.2 more explicit as follows. If $A \in \mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ and $1$ is the unit object of $\mathcal{C}$, we will say that a map $u : 1 \rightarrow A$ is a quasi-unit for $A$ if its homotopy class is both a left and right unit with respect to the multiplication on $A$, as in Definition 5.4.3.5. Then $A$ belongs to $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ if and only if it admits a quasi-unit $u$; in this case, $u$ is determined uniquely up to homotopy. A morphism $f : A \rightarrow B$ belongs to $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ if and only if $u$ admits a quasi-unit $q : 1 \rightarrow A$ and the composite map $f \circ u$ is a quasi-unit for $B$.

**Remark 5.4.4.4.** In the situation of Remark 5.4.4.3, a map $e : 1 \rightarrow A$ is a quasi-unit for $A$ if and only if each of the composite maps

$$A \simeq 1 \otimes A \overset{e \otimes id}{\rightarrow} A \otimes A \overset{id \otimes e}{\rightarrow} A \otimes A \overset{m}{\rightarrow} A$$

is homotopy to the identity. If $k > 1$, then the multiplication on $A$ and the tensor product on $\mathcal{C}$ are commutative up to homotopy, so these conditions are equivalent to one another.

Let $q : \mathcal{C}_\circ^{\otimes} \rightarrow \mathbb{E}_k^{\otimes}$ be a coCartesian fibration of $\infty$-operads, and let $\theta : \mathcal{A}_{\mathcal{E}_k}(\mathcal{C}) \rightarrow \mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ be the restriction functor. Then $\theta$ carries $\mathcal{E}_k$-algebra objects $\mathcal{C}$ to quasi-unital objects of $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$, and morphisms of $\mathcal{E}_k$-algebras to quasi-unital morphisms in $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$. Consequently, $\theta$ can be viewed as a functor from $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ to $\mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$. The main result of this section is the following generalization of Theorem 5.4.3.8:

**Theorem 5.4.4.5.** Let $k \geq 1$ and let $q : \mathcal{C}_\circ^{\otimes} \rightarrow \mathbb{E}_k^{\otimes}$ be a coCartesian fibration of $\infty$-operads. Then the forgetful functor $\theta : \mathcal{A}_{\mathcal{E}_k}(\mathcal{C}) \rightarrow \mathcal{A}_{\mathcal{E}_k}(\mathcal{C})$ is an equivalence of $\infty$-categories.
The proof of Theorem 5.4.4.5 is somewhat elaborate, and will be given at the end of this section.

**Remark 5.4.4.6.** In the situation of Theorem 5.4.4.5, we may assume without loss of generality that \( \mathcal{C}^\circ \) is small (filtering \( \mathcal{C}^\circ \) if necessary). Using Proposition 4.8.1.10, we deduce the existence of a presentable \( \mathbb{E}_k \)-monoidal \( \infty \)-category \( \mathcal{D}^\circ \to \mathbb{E}_k^\circ \) and a fully faithful \( \mathbb{E}_k \)-monoidal functor \( \mathcal{C}^\circ \to \mathcal{D}^\circ \). We have a commutative diagram

\[
\begin{array}{ccc}
\text{Alg}_{/\mathbb{E}_k}(\mathcal{C}) & \longrightarrow & \text{Alg}_{/\mathbb{E}_k}(\mathcal{D}) \\
\downarrow \phi & & \downarrow \phi' \\
\text{Alg}_{/\mathbb{E}_k}^{\text{qu}}(\mathcal{C}) & \longrightarrow & \text{Alg}_{/\mathbb{E}_k}^{\text{qu}}(\mathcal{D})
\end{array}
\]

where the horizontal maps are fully faithful embeddings, whose essential images consist of those (unit or nonunit) \( \mathbb{E}_k \)-algebra objects of \( \mathcal{D} \) whose underlying object belongs to the essential image of the embedding \( \mathcal{C} \to \mathcal{D} \). To prove that \( \theta \) is a categorical equivalence, it suffices to show that \( \theta' \) is a categorical equivalence. In other words, it suffices to prove Theorem 5.4.4.5 in the special case where \( \mathcal{C}^\circ \) is a presentable \( \mathbb{E}_k \)-monoidal \( \infty \)-category.

We will use Theorem 5.4.4.5 to deduce an analogous assertion regarding commutative algebras. Let \( \mathcal{C}^\circ \) be a symmetric monoidal \( \infty \)-category. We let \( \text{CAlg}^{\text{qu}}(\mathcal{C}) \) denote the \( \infty \)-category \( \text{CAlg}^{\text{qu}}_\text{Comm}(\mathcal{C}) \) of nonunit commutative algebra objects of \( \mathcal{C} \). Definition 5.4.4.2 has an evident analogue for nonunital commutative algebras and maps between them: we will say that a nonunital commutative algebra is *quasi-unital* if there exists a map \( e : 1 \to A \) in \( \mathcal{C} \) such that the composition

\[
A \simeq 1 \otimes A \xrightarrow{e \otimes \text{id}} A \otimes A \to A
\]

is homotopic to the identity (in the \( \infty \)-category \( \mathcal{C} \)). In this case, \( e \) is uniquely determined up to homotopy and we say that \( e \) is a quasi-unit for \( A \); a morphism \( f : A \to B \) in \( \text{CAlg}^{\text{qu}}(\mathcal{C}) \) is *quasi-unital* if \( A \) admits a quasi-unit \( e : 1 \to A \) such that \( f \circ e \) is a quasi-unit for \( B \). The collection of quasi-unital commutative algebras and quasi-unital morphisms between them can be organized into a subcategory \( \text{CAlg}^{\text{qu}}(\mathcal{C}) \subseteq \text{CAlg}^{\text{nu}}(\mathcal{C}) \).

**Corollary 5.4.4.7.** Let \( \mathcal{C}^\circ \) be a symmetric monoidal \( \infty \)-category. Then the forgetful functor \( \text{CAlg}(\mathcal{C}) \to \text{CAlg}^{\text{qu}}(\mathcal{C}) \) is an equivalence of \( \infty \)-categories.

**Proof.** In view of Corollary 5.1.1.5, we have an equivalence of \( \infty \)-operads \( \varinjlim \mathbb{E}_k^\circ \to \text{Comm}^\circ = \mathbb{E}_\infty^\circ \). It will therefore suffice to show that the forgetful functor \( \text{Alg}_{/\mathbb{E}_k}(\mathcal{C}) \to \text{Alg}_{/\mathbb{E}_k}^{\text{qu}}(\mathcal{C}) \) is an equivalence of \( \infty \)-categories. This map is the homotopy inverse limit of a tower of forgetful functors \( \theta_k : \text{Alg}_{/\mathbb{E}_k}(\mathcal{C}) \to \text{Alg}_{/\mathbb{E}_k}^{\text{qu}}(\mathcal{C}) \), each of which is an equivalence of \( \infty \)-categories by Theorem 5.4.4.5.

As a first step toward understanding the forgetful functor \( \theta : \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{C}) \), let us study the left adjoint to \( \theta \). In classical algebra, if \( A \) is a nonunital ring, then we can canonically enlarge \( A \) to a unital ring by considering the product \( A \otimes \mathbb{Z} \) endowed with the multiplication \( (a,m)(b,n) = (ab+mb+na,mn) \). Our next result shows that this construction works quite generally:

**Proposition 5.4.4.8.** Let \( \mathcal{O}^\circ \) be a unital \( \infty \)-operad, let \( q : \mathcal{C}^\circ \to \mathcal{O}^\circ \) be a coCartesian fibration of \( \infty \)-operads which is compatible with finite coproducts, and let \( \theta : \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{C}) \) be the forgetful functor. Then:

1. For every object \( A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \), there exists another object \( A^+ \in \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \) and a map \( A \to \theta(A^+) \) which exhibits \( A^+ \) as a free \( \mathcal{O} \)-algebra generated by \( A \).

2. A morphism \( f : A \to \theta(A^+) \) in \( \text{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{C}) \) exhibits \( A^+ \) as a free \( \mathcal{O} \)-algebra generated by \( A \) if and only if, for every object \( X \in \mathcal{O} \), the map \( f_X : A(X) \to A^+(X) \) and the unit map \( 1_X \to A^+(X) \) exhibit \( A^+(X) \) as a coproduct of \( A(X) \) and the unit object \( 1_X \) in the \( \infty \)-category \( \mathcal{C}_X \).
(3) The functor $\theta$ admits a left adjoint.

Proof. For every object $X \in \mathcal{O}$, the $\infty$-category $\mathcal{D} = \mathcal{O}\otimes_{\mathcal{O}^{\otimes}}(\mathcal{O}^{\otimes})_{act}$ can be written as a disjoint union of $\mathcal{D}_0 = (\mathcal{O}\otimes_{\mathcal{O}^{\otimes}})^{act}_{X}$ with the full subcategory $\mathcal{D}_1 \subseteq \mathcal{D}$ spanned by those morphisms $X' \to X$ in $\mathcal{O}^{\otimes}$ where $X' \in \mathcal{O}^{\otimes}_{(0)}$. The $\infty$-category $\mathcal{D}_0$ contains $id_X$ as a final object. Since $\mathcal{O}^{\otimes}$ is unital, the $\infty$-category $\mathcal{D}_1$ is a contractible Kan complex containing a vertex $v : X_0 \to X$. It follows that the inclusion $\{id_X, v\}$ is left cofinal in $\mathcal{D}$. Assertions (1) and (2) now follow from Proposition 3.1.3.3 (together with Propositions 3.1.1.15 and 3.1.1.16). Assertion (3) follows from (1) (Corollary 3.1.3.4).

In the stable setting, there is a close relationship between nonunital algebras and augmented algebras. To be more precise, we need to introduce a bit of terminology.

**Definition 5.4.4.9.** Let $q : \mathcal{E}^{\otimes} \to \mathcal{O}^{\otimes}$ be a coCartesian fibration of $\infty$-operads, and assume that $\mathcal{O}^{\otimes}$ is unital. An augmented $\mathcal{O}$-algebra object of $\mathcal{E}$ is a morphism $f : \mathcal{A} \to \mathcal{A}_0$ in $\mathcal{Alg}_{/\mathcal{O}}^{\text{aug}}(\mathcal{E})$, where $\mathcal{A}_0$ is a trivial algebra. We let $\mathcal{Alg}_{/\mathcal{O}}^{\text{aug}}(\mathcal{E})$ denote the full subcategory of $\mathcal{Fun}(\Delta^1, \mathcal{Alg}_{/\mathcal{O}}^{\text{aug}}(\mathcal{E}))$ spanned by the augmented $\mathcal{O}$-algebra objects of $\mathcal{E}$.

The following result will not play a role in the proof of Theorem 5.4.4.5, but is of some independent interest:

**Proposition 5.4.4.10.** Let $q : \mathcal{E}^{\otimes} \to \mathcal{O}^{\otimes}$ be a coCartesian fibration of $\infty$-operads. Assume that $\mathcal{O}^{\otimes}$ is unital and that $q$ exhibits $\mathcal{E}$ as a stable $\mathcal{O}$-monoidal $\infty$-category. Let $F : \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E}) \to \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$ be a left adjoint to the forgetful functor $\mathcal{O} : \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E}) \to \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$. Let $0 \in \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$ be a final object, so that $F(0) \in \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$ is a trivial algebra (Proposition 5.4.4.8). Then $F$ induces an equivalence of $\infty$-categories

$$T : \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E}) \simeq \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})^{/0} \to \mathcal{Alg}_{/\mathcal{O}}^{\text{aug}}(\mathcal{E}).$$

Proof. Let $p : \mathcal{M} \to \Delta^1$ be a correspondence associated to the adjunction $\mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E}) \rightleftarrows \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$. Let $\mathcal{D}$ denote the full subcategory of $\mathcal{Fun}_{\Delta^1}(\Delta^1 \times \Delta^1, \mathcal{M})$ spanned by those diagrams $\sigma$

$$\begin{array}{ccc}
A & \xrightarrow{f} & A^+ \\
\downarrow{g} & & \downarrow{g'} \\
A_0 & \xrightarrow{f_0} & A^+_0
\end{array}$$

where $A_0$ is a final object of $\mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$ and the maps $f$ and $f'$ are $p$-coCartesian; this (together with Proposition 5.4.4.8) guarantees that $A^+_0 \in \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$ is a trivial algebra so that $g$ can be regarded as an augmented $\mathcal{O}$-algebra object of $\mathcal{E}$. Using Proposition T.4.3.2.15, we deduce that the restriction functor $\sigma \mapsto A$ determines a trivial Kan fibration $\mathcal{D} \to \mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$. By definition, the functor $T$ is obtained by composing a section of this trivial Kan fibration with the restriction map $\phi : \mathcal{D} \to \mathcal{Alg}_{/\mathcal{O}}^{\text{aug}}(\mathcal{E})$ given by $\sigma \mapsto g$. To complete the proof, it will suffice to show that $\phi$ is a trivial Kan fibration.

Let $K$ denote the full subcategory of $\Delta^1 \times \Delta^1$ obtained by removing the object $((0, 0))$, and let $\mathcal{D}_0$ be the full subcategory of $\mathcal{Fun}_{\Delta^1}(K, \mathcal{M})$ spanned by those diagrams

$$\begin{array}{ccc}
A^+ & \xrightarrow{\phi} & A^+_0 \\
\downarrow{f_0} & & \downarrow{f_0} \\
A_0 & \xrightarrow{f_0} & A_0
\end{array}$$

where $A_0$ is a final object of $\mathcal{Alg}_{/\mathcal{O}}^{\text{nu}}(\mathcal{E})$ and $A_0^+$ is a trivial $\mathcal{O}$-algebra object of $\mathcal{E}$; note that this last condition is equivalent to the requirement that $f_0$ be $p$-coCartesian. The functor $\phi$ factors as a composition

$$\begin{array}{ccc}
\mathcal{D} & \xrightarrow{\xi} & \mathcal{D}_0 \\
\phi & \xrightarrow{\phi'} & \mathcal{Alg}_{/\mathcal{O}}^{\text{aug}}(\mathcal{E}).
\end{array}$$
We will prove that $\phi'$ and $\phi''$ are trivial Kan fibrations.

Let $D_1$ be the full subcategory of $\text{Fun}_{\Delta^1}(\Delta^1, M)$ spanned by the $p$-coCartesian morphisms $f_0 : A_0 \to A_0^+$ where $A_0$ is a final object of $\text{Alg}_{/O}(C)$. It follows from Proposition T.4.3.2.15 that the restriction map $f_0 \mapsto A_0^+$ determines a trivial Kan fibration from $D_1$ to the contractible Kan complex of final objects in $\text{Alg}_{/O}(C)$, so that $D_1$ is contractible. The restriction map $f_0 \mapsto A_0^+$ is a categorical fibration $\phi''$ from $D_1$ onto the contractible Kan complex of initial objects of $\text{Alg}_{/O}(C)$. It follows that $\phi''$ is a trivial Kan fibration.

The map $\phi''$ is a pullback of $\phi'$, and therefore also a trivial Kan fibration.

We now complete the proof by showing that $\phi'$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to show that a diagram $\sigma \in \text{Fun}_{\Delta^1}(\Delta^1 \times \Delta^1, M)$ belongs to $D_1$ if and only if $\sigma_0 = \sigma|K$ belongs to $D_0$ and $\sigma$ is a $p$-right Kan extension of $\sigma_0$. Unwinding the definitions (and using Corollary 3.2.2.5), we are reduced to showing that if we are given a diagram

$$
\begin{array}{c}
A \\
\downarrow \\
A_0
\end{array} \xrightarrow{f} 
\begin{array}{c}
A^+ \\
\downarrow \\
A_0^+
\end{array}
$$

where $A_0$ is a final object of $\text{Alg}_{/O}(C)$ and $A_0^+$ is a trivial algebra, then $f$ is $p$-coCartesian if and only if the induced diagram

$$
\begin{array}{c}
A(X) \\
\downarrow \\
A_0(X)
\end{array} \xrightarrow{f_X} 
\begin{array}{c}
A^+(X) \\
\downarrow \\
A_0^+(X)
\end{array}
$$

is a pullback square in $\mathcal{C}_X$, for each $X \in O$. Since $\mathcal{C}_X$ is a stable $\infty$-category, this is equivalent to the requirement that the induced map $\psi : \text{cofib}(f_X) \to A_0^+(X)$ is an equivalence. The map $\psi$ fits into a commutative diagram

$$
\begin{array}{c}
1_X \\
\downarrow \\
A^+(X)
\end{array} \xrightarrow{\text{cofib}(f)} 
\begin{array}{c}
1_X \\
\downarrow \\
A_0^+(X)
\end{array}
$$

where the vertical maps are given by the units for the algebra objects $A^+$ and $A_0^+$. Since $A_0^+(X)$ is a trivial algebra, the unit map $1_X \to A_0^+(X)$ is an equivalence. Consequently, it suffices to show that $f$ is $p$-coCartesian if and only if each of the composite maps $1_X \to A^+(X) \to \text{cofib}(f)$ is an equivalence. We have a pushout diagram

$$
\begin{array}{c}
1_X \coprod A(X) \\
\downarrow \\
1_X
\end{array} \xrightarrow{A(X)} 
\begin{array}{c}
A^+(X) \\
\downarrow \\
\text{cofib}(f)
\end{array}
$$

Since $\mathcal{C}_X$ is stable, the lower horizontal map is an equivalence if and only if the upper horizontal map is an equivalence. The desired result now follows immediately from the criterion described in Proposition 5.4.4.8. \qed

Let us now return to the proof of Theorem 5.4.4.5. The case $k = 1$ follows immediately from Theorem 5.4.3.8. The proof of Theorem 5.4.4.5 in general will proceed by induction on $k$. For the remainder of this section, we will fix an integer $k \geq 1$, and assume that Theorem 5.4.4.5 has been verified for the $\infty$-operad $E_k$. Our goal is to prove that Theorem 5.4.4.5 is valid also for $E_{k+1}$. Fix a coCartesian fibration of $\infty$-operads
q : C^\infty \to E^\infty_{k+1}; we wish to show that the forgetful functor \theta : \text{Alg}_{/E_{k+1}}(C) \to \text{Alg}_{/E_{k+1}}^{\text{nu}}(C) is an equivalence of \infty-categories. In view of Remark 5.4.4.6, we can assume that C^\infty is a presentable E_{k+1}-monoidal \infty-category.

We begin by constructing a left homotopy inverse to \theta. Consider the bifunctor of \infty-operads E^\infty_k \times E^\infty_k \to E^\infty_{k+1} of §5.1.2. Using this bifunctor, we can define E_1-monoidal \infty-categories \text{Alg}_{E_k/E_{k+1}}(C)^{\otimes} and \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)^{\otimes}. Moreover, the collection of quasi-unital E_k-algebras and quasi-unital morphisms between them are stable under tensor products, so we can also consider an E_1-monoidal subcategory \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)^{\otimes} \subseteq \text{Alg}_{E_k/E_{k+1}}(C)^{\otimes}. By the same reasoning, we have E_k-monoidal \infty-categories \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)^{\otimes}, \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)^{\otimes}, and \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)^{\otimes}.

There is an evident forgetful functor \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) \to \text{Alg}_{E_k/E_{k+1}}(C), which obviously restricts to a functor \psi_0 : \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) \to \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C). Using the inductive hypothesis (and Corollary T.2.4.4.4), we deduce that the evident categorical fibration \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)^{\otimes} \to \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)^{\otimes} is a categorical equivalence and therefore a trivial Kan fibration. It follows that the induced map

\text{Alg}_{E_k/E_{k+1}}(C) \to \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)

is a trivial Kan fibration, which admits a section \psi_1. Let \psi_2 be the evident equivalence

\text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) \simeq \text{Alg}_{E_k/E_{k+1}}(C).

We observe that the composition \psi_2 \circ \psi_1 \circ \psi_0 carries \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) into the subcategory

\text{Alg}_{E_k/E_{k+1}}(C) \subseteq \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C).

Using the inductive hypothesis and Corollary T.2.4.4.4 again, we deduce that the forgetful functor

\text{Alg}_{E_k/E_{k+1}}(C) \to \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C)

is a trivial Kan fibration, which admits a section \psi_3. Finally, Theorem 5.1.2.2 implies that the functor \text{Alg}_{E_k/E_{k+1}}(C) \to \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) is an equivalence of \infty-categories which admits a homotopy inverse \psi_4. Let \psi denote the composition \psi_4 \psi_3 \psi_2 \psi_1 \psi_0. Then \psi is a functor from \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) to \text{Alg}_{E_k/E_{k+1}}(C).

The composition \psi \circ \theta becomes homotopic to the identity after composing with the functor \text{Alg}_{E_k/E_{k+1}}(C) \simeq \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) \subseteq \text{Alg}_{E_k/E_{k+1}}(C), and is therefore homotopic to the identity on \text{Alg}_{E_k/E_{k+1}}(C).

To complete the proof of Theorem 5.4.4.5, it will suffice to show that the composition \theta \circ \psi is equivalent to the identity functor from \text{Alg}_{E_k/E_{k+1}}^{\text{nu}}(C) to itself. This is substantially more difficult, and the proof will require a brief digression. In what follows, we will assume that the reader is familiar with the theory of centralizers of maps of E_k-algebras developed in §4.3.3.7 (see Definition 5.3.1.2).

**Definition 5.4.4.11.** Let C^\infty \to E^\infty_k be a coCartesian fibration of \infty-operads, let A and B be E_k-algebra objects of C, and let u : 1 \to A be a morphism in C. We let Map_{\text{Alg}_{E_k}(C)}^{\text{nu}}(A, B) be the summand of the mapping space Map_{\text{Alg}_{E_k}(C)}(A, B) given by those maps f : A \to B such that f \circ u is an invertible element in the monoid Hom_{E_k}(1, B).

Let f : A \to B be a morphism in \text{Alg}_{E_k}(C) and let u : 1 \to A be as above. We will say that f is a u-equivalence if, for every object C in \text{Alg}_{E_k}(C), composition with f induces a homotopy equivalence

Map_{\text{Alg}_{E_k}(C)}^{\text{nu}}(B, C) \to Map_{\text{Alg}_{E_k}(C)}(A, C).

**Remark 5.4.4.12.** Let M be an associative monoid. If x and y are commuting elements of M, then the product xy = yx is invertible if and only if both x and y are invertible. In the situation of Definition 5.4.11, this guarantees that if u : 1 \to A and v : 1 \to A are morphisms in C such that u and v commute in the monoid Hom_{E_k}(1, A) and w denotes the product map 1 \simeq 1 \circ 1 \overset{u \circ v}{\to} A \circ A \to A, then we have Map_{\text{Alg}_{E_k}(C)}^{\text{nu}}(A, B) = Map_{\text{Alg}_{E_k}(C)}^{\text{nu}}(A, B) \cap Map_{\text{Alg}_{E_k}(C)}^{\text{nu}}(A, B) (where the intersection is formed in the mapping space Map_{\text{Alg}_{E_k}(C)}(A, B)). It follows that if f : A \to B is a u-equivalence or a v-equivalence, then it is also a w-equivalence.
Remark 5.4.4.13. Let $\mathcal{C} \to \mathcal{E}_{k}^{\otimes}$ be a presentable $\mathcal{E}_{k}$-monoidal $\infty$-category, and let $e : 1 \to A$ be the unit map for an $\mathcal{E}_{k}$-algebra object $A \in \text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})$. We will abuse notation by identifying $A$ with the underlying nonunital $\mathcal{E}_{k}$-algebra object, and let $A^{+}$ be the free $\mathcal{E}_{k}$-algebra generated by this nonunital $\mathcal{E}_{k}$-algebra (see Proposition 5.4.4.8). Let $e^{+}$ denote the composite map $1 \xrightarrow{e} A \to A^{+}$. Then the counit map $\nu : A^{+} \to A$ is an $e^{+}$-equivalence. To see this, it suffices to show that for every object $B \in \text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})$, composition with $\nu$ induces a homotopy equivalence

$$\text{Map}_{\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})}(A, B) \xrightarrow{\text{Map}_{\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})}(e^{+})} \text{Map}_{\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})}(A^{+}, B).$$

Note that any nonunital algebra morphism $f : A \to B$ carries $e$ to an idempotent element $[f \circ e]$ of the monoid $\text{Hom}_{\mathcal{E}_{k}}(1, B)$, so $f \circ e$ is a quasi-unit for $B$ if and only if $[f \circ e]$ is invertible. Consequently, the homotopy equivalence $\text{Map}_{\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})}(A^{+}, B) \simeq \text{Map}_{\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})}(A, B)$ induces an identification $\text{Map}_{\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})}(A^{+}, B) \simeq \text{Map}_{\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})}(A, B)$. The desired result now follows from the inductive hypothesis.

Lemma 5.4.4.14. Let $q : \mathcal{C} \to \mathcal{E}_{k+1}^{\otimes}$ be a presentable $\mathcal{E}_{k+1}$-monoidal $\infty$-category, so that $\text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})$ inherits the structure of an $\mathcal{E}_{1}$-monoidal $\infty$-category. Let $f : A \to A'$ be a morphism in $\text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})$, and let $u : 1 \to A$ be a morphism in $\mathcal{C}$ such that $f$ is a $u$-equivalence. Let $B \in \text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})$ and $v : 1 \to B$ be an arbitrary morphism in $\mathcal{C}$. Then:

1. The induced map $f \otimes \text{id}_{B}$ is a $u \otimes v : 1 \to A \otimes B$ equivalence.
2. The induced map $\text{id}_{B} \otimes f$ is a $v \otimes u : 1 \to B \otimes A$-equivalence.

Proof. We will prove (1); the proof of (2) is similar. Let $e_{A} : 1 \to A$ and $e_{B} : 1 \to B$ denote the units of $A$ and $B$, respectively. We note that $u \otimes v$ is homotopic to the product of maps $e_{A} \otimes v$ and $u \otimes e_{B}$ which commute in the monoid $\text{Hom}_{\mathcal{E}_{k}}(1, A \otimes B)$. By virtue of Remark 5.4.4.12, it will suffice to show that $f \otimes \text{id}_{B}$ is a $u$-equivalence, where $w = u \otimes e_{B}$.

Let $w'$ be the composition of $w$ with $f \otimes \text{id}_{B}$, and let $C \in \text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})$. We have a commutative diagram

$$\text{Map}_{\text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})}(A', B, C) \xrightarrow{\text{Map}_{\text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})}(f \otimes \text{id}_{B})} \text{Map}_{\text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})}(A \otimes B, C)$$

and we wish to show that the horizontal map is a homotopy equivalence. It will suffice to show that this map induces a homotopy equivalence after passing to the homotopy fibers over any map $g : B \to C$. This is equivalent to the requirement that $f$ induces a homotopy equivalence $\text{Map}_{\text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})}(A', 3_{\mathcal{E}_{k}}(g)) \to \text{Map}_{\text{Alg}_{/\mathcal{E}_{k+1}}(\mathcal{C})}(A, 3_{\mathcal{E}_{k}}(g))$, which follows from our assumption that $f$ is a $u$-equivalence.

Lemma 5.4.4.15. Let $\mathcal{C} \to \mathcal{E}_{k}^{\otimes}$ be a presentable $\mathcal{E}_{k}$-monoidal $\infty$-category, let $A \in \text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})$, and let $u : 1 \to A$ be a morphism in the underlying $\infty$-category $\mathcal{C}$. Then there exists a morphism $f : A \to A[u^{-1}]$ in $\text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C})$ with the following universal properties:

1. The map $f$ is a $u$-equivalence.
2. The composite map $fu$ is a unit in the monoid $\text{Hom}_{\mathcal{E}_{k}}(1, A[u^{-1}])$.

Proof. Let $L : \text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C}) \to \text{Mon}_{\mathcal{E}_{k}}(\mathcal{S})$ be the functor described in §5.2.6. The inclusion $\text{Mon}_{\mathcal{E}_{k}}^{\text{gp}}(\mathcal{S}) \subseteq \text{Mon}_{\mathcal{E}_{k}}(\mathcal{S})$ admits a right adjoint $G$ which can be described informally as follows: $G$ carries an $\mathcal{E}_{k}$-space $X$ to the subspace $X^{\text{gp}} \subseteq X$ given by the union of those connected components of $X$ which are invertible in $\pi_{0}X$. Let $J : \text{Mon}_{\mathcal{E}_{k}}(\mathcal{S}) \to \mathcal{S}$ be the forgetful functor, and let $\chi : \text{Alg}_{/\mathcal{E}_{k}}(\mathcal{C}) \to \mathcal{S}$ be the functor corepresented by
A. We can identify $u$ with a point in the space $JP(A)$, which determines natural transformation of functors $\chi \to JP$. Let $\chi$ denote the fiber product $\chi \times_{JP} JP$ in the $\infty$-category $\Fun(\Alg_{/E_k}(\mathcal{C}), \mathcal{S})$. Since $\chi$, $J$, $G$, and $P$ are all accessible functors which preserve small limits, the functor $\chi'$ is accessible and preserves small limits, and is therefore corepresentable by an object $A[u^{-1}] \in \Alg_{/E_k}(\mathcal{C})$ (Proposition T.5.5.2.7). The evident map $\chi' \to \chi$ induces a map $f : A \to A[u^{-1}]$ which is easily seen to have the desired properties.

Remark 5.4.4.16. Let $\mathcal{C}^\otimes \to E_k^\otimes$ be as in Lemma 5.4.4.15, let $f : A \to B$ be a morphism in $\Alg_{/E_k}(\mathcal{C})$ and let $u : 1 \to A$ be a morphism in $\mathcal{C}$. Then $f$ is a $u$-equivalence if and only if it induces an equivalence $A[u^{-1}] \to (fu)^{-1}$ in the $\infty$-category $\Alg_{/E_k}(\mathcal{C})$.

Example 5.4.4.17. Let $A \in \Alg_{/E_k}^{nu}(\mathcal{C})$ be a nonunital algebra equipped with a quasi-unit $e_A : 1 \to A$. Let $A^+ \in \Alg_{/E_k}(\mathcal{C})$ be an algebra equipped with a nonunital algebra map $\beta : A \to A^+$ which exhibits $A^+$ as the free $E_k$-algebra generated by $A$. Then the composite map $\gamma_0 : A \to A^+ \to A^+[(\beta e_A)^{-1}]$ is quasi-unital, and therefore (by the inductive hypothesis) lifts to an $E_k$-algebra map $\gamma : A \to A^+[(\beta e_A)^{-1}]$. Using the inductive hypothesis again, we deduce that $\gamma$ is an equivalence in $\Alg_{/E_k}(\mathcal{C})$, so that $\gamma_0$ is an equivalence of nonunital algebras.

We now return to the proof of Theorem 5.4.4.5 for a presentable $E_{k+1}$-monoidal $\infty$-category $\mathcal{C}^\otimes \to E_k^\otimes$. We will assume that Theorem 5.4.4.5 holds for the $\infty$-operad $E_k^\otimes$, so that the forgetful functor $\Alg_{/E_k}(\mathcal{C}) \to \Alg_{/E_k}(\mathcal{C})$ is an equivalence of $\infty$-categories. Consequently, all of the notions defined above for $E_k$-algebras make sense also in the context of quasi-unital $E_k$-algebras; we will make use of this observation implicitly in what follows.

Let $\mathcal{D}$ denote the fiber product

\[
\Fun(\partial \Delta^1, \Alg_{/E_k}(\mathcal{C})) \times_{\Fun(\partial \Delta^1, \Alg_{/E_k}(\mathcal{C}))} \Fun(\Delta^1, \Alg_{/E_k}(\mathcal{C}))
\]

whose objects are nonunital maps $f : A \to B$ between quasi-unital $E_k$-algebra objects of $\mathcal{C}$, and whose morphisms are given by commutative diagrams

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow & & \downarrow \\
A' & \xrightarrow{f'} & B'
\end{array}
\]

where the vertical maps are quasi-unital. Let $\mathcal{D}_0$ denote the full subcategory $\Fun(\Delta^1, \Alg_{/E_k}(\mathcal{C})) \subseteq \mathcal{D}$ spanned by the quasi-unital maps $f : A \to B$. The inclusion $\mathcal{D}_0 \hookrightarrow \mathcal{D}$ admits a left adjoint $L$, given informally by the formula $(f : A \to B) \mapsto (A \to B[(fe_A)^{-1}])$, where $e_A : 1 \to A$ denotes the unit of $A$. Using Remark 5.4.4.16, we deduce the following:

Lemma 5.4.4.18. If $\alpha$ is a morphism in $\mathcal{D}$ corresponding to a commutative diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow g & & \downarrow g' \\
A' & \xrightarrow{f'} & B'
\end{array}
\]

then $L(\alpha)$ is an equivalence if and only if the following pair of conditions is satisfied:

(i) The map $g$ is an equivalence.

(ii) The map $g'$ is an $fe_A$-equivalence, where $e_A : 1 \to A$ denotes a quasi-unit for $A$. 

Note that the $E_1$-monoidal structure on $\text{Alg}^{nu}_{E_k/\mathbb{E}_k} (\mathcal{E})$ induces an $E_1$-monoidal structure on the $\infty$-category $\mathcal{D}$.

**Lemma 5.4.4.19.** The localization functor $L : \mathcal{D} \to \mathcal{D}_0 \subseteq \mathcal{D}$ is compatible with the $E_1$-monoidal structure on $\mathcal{D}$. In other words, if $\alpha : D \to D'$ is an $L$-equivalence in $\mathcal{D}$ and $E$ is any object of $\mathcal{D}$, then the induced maps $D \otimes E \to D' \otimes E$ and $E \otimes D \to E \otimes D'$ are again $L$-equivalences.

**Proof.** Combine Lemmas 5.4.4.18 and 5.4.4.14. \hfill \square

Combining Lemma 5.4.4.19 with Proposition 2.2.1.9, we deduce that $L$ ispromoted to an $E_1$-monoidal functor from $\mathcal{D}$ to $\mathcal{D}_0$; in particular, $L$ induces a functor $L' : \text{Alg}^{nu}_{/E_k} (\mathcal{D}) \to \text{Alg}^{nu}_{/E_k} (\mathcal{D}_0)$ which is left adjoint to the inclusion and therefore comes equipped with a natural transformation $\alpha : \text{id}_{\text{Alg}^{nu}_{/E_k} (\mathcal{D})} \to L'$.

We are now ready to complete the proof of Theorem 5.4.4.5. Let $G : \text{Alg}_{/E_k+1} (\mathcal{E}) \to \text{Alg}^{nu}_{/E_k+1} (\mathcal{E})$ denote the forgetful functor, let $F$ be a left adjoint to $G$ (Proposition 5.4.4.10), and let $\beta : \text{id}_{\text{Alg}^{nu}_{/E_k+1} (\mathcal{E})} \to G \circ F$ be a unit transformation. Let $j : \text{Alg}^{nu}_{/E_k+1} (\mathcal{E}) \to \text{Alg}^{nu}_{/E_k} (\mathcal{E})$ be the inclusion functor and let $\xi : \text{Alg}^{nu}_{/E_k+1} (\mathcal{E}) \to \text{Alg}^{nu}_{/E_k} (\text{Alg}^{nu}_{E_k/\mathbb{E}_k+1} (\mathcal{E}))$ be the forgetful functor. If $A \in \text{Alg}^{nu}_{/E_k+1} (\mathcal{E})$ is quasi-unital, then $GF(A)$ is likewise quasi-unital. Consequently, the construction $A \mapsto \xi(\beta A)$ induces a functor $\epsilon : \text{Alg}^{nu}_{/E_k+1} (\mathcal{E}) \to \text{Alg}^{nu}_{/E_k} (\mathcal{E})$. Let $L'$ and $\alpha : \text{id} \to L'$ be defined as above. The induced natural transformation $\epsilon \to L' \epsilon$ can be regarded as a functor from $\text{Alg}_{/E_k+1} (\mathcal{E})$ to $\text{Fun}(\Delta^1 \times \Delta^1, \text{Alg}^{nu}_{/E_k} (\text{Alg}^{nu}_{E_k/\mathbb{E}_k+1} (\mathcal{E})))$. This functor can be described informally as follows: it carries a quasi-unital algebra $A$ to the diagram

\[
\begin{array}{ccc}
A & \xrightarrow{\beta A} & F(A) \\
\downarrow & & \downarrow \\
A & \xrightarrow{F(A)(\beta A e_A)^{-1}} & F(A)(\beta A e_A)^{-1},
\end{array}
\]

where $e_A : 1 \to A$ denotes the quasi-unit of $A$. It follows from Example 5.4.4.17 that the lower horizontal map is an equivalence. Consequently, the above functor can be regarded as a natural transformation from $\xi GF j$ to $\xi j$ in the $\infty$-category $\text{Fun}(\text{Alg}^{nu}_{E_k/\mathbb{E}_k+1} (\mathcal{E}), \text{Alg}^{nu}_{/E_k} (\text{Alg}^{nu}_{E_k/\mathbb{E}_k+1} (\mathcal{E})))$. Composing with $\psi_1 \circ \psi_3 \circ \psi_2 \circ \psi_1$, we obtain a natural transformation $\delta : \psi \theta F \to \psi$ of functors from $\text{Alg}^{nu}_{/E_k+1} (\mathcal{E})$ to $\text{Alg}^{nu}_{E_k/\mathbb{E}_k+1} (\mathcal{E})$. Since $\psi \theta$ is homotopic to the identity, we can view $\delta$ as a natural transformation from $F|_{\text{Alg}^{nu}_{/E_k+1} (\mathcal{E})}$ to $\psi$. This transformation is adjoint to a map of functors $\text{id}_{\text{Alg}^{nu}_{/E_k+1} (\mathcal{E})} \to \theta \circ \psi$. It is easy to see that this transformation is an equivalence (using the fact that the forgetful functor $\text{Alg}^{nu}_{/E_k+1} (\mathcal{E}) \to \mathcal{E}$ is conservative, by Lemma 3.2.2.6), so that $\psi$ is a right homotopy inverse to $\theta$. This completes the proof of Theorem 5.4.4.5.

### 5.4.5 Little Cubes in a Manifold

Let $M$ be a topological space equipped with an $R^k$-bundle $\zeta \to M$. Assuming that $M$ is sufficiently nice, we can choose a Kan complex $B$ such that $X$ is homotopy equivalent to the geometric realization $|B|$, and the bundle $\zeta$ is classified by a Kan fibration of simplicial sets $\theta : B \to B\text{Top}(k)$. In this case, we can apply the construction of Definition 5.4.2.10 to obtain an $\infty$-operad $E_B^{\otimes}$. In the special case where $M$ is a topological manifold of dimension $k$ and $\zeta$ is the tangent bundle of $M$, we will denote this $\infty$-operad by $E_{\mathbb{M}}^{\otimes}$ (see Definition 5.4.5.1 below for a precise definition). We can think of $E^{\otimes}_{\mathbb{M}}$ as a variation on the $\infty$-operad $E_{\mathbb{R}}^{\otimes}$ whose objects are cubes $\square^k$ equipped with an open embedding into $M$, and whose morphisms are required to be compatible with these open embeddings (up to specified isotopy). We will also consider a more rigid version of the $\infty$-operad $E^{\otimes}_{\mathbb{M}}$, where the morphisms are required to be strictly compatible with the embeddings into $M$ (rather than merely up to isotopy); this $\infty$-operad will be denoted by $N(\text{Disk}(M))^{\otimes}$ (Definition 5.4.5.6). The main result of this section is Theorem 5.4.5.9, which asserts that theory of $E_{\mathbb{M}}$-algebras is closely related to the more rigid theory of $N(\text{Disk}(M))^{\otimes}$-algebras.

Our first step is to define the $\infty$-operad $E^{\otimes}_{\mathbb{M}}$ more precisely.
Definition 5.4.5.1. Let $M$ be a topological manifold of dimension $k$. We define a topological category $\mathcal{C}_M$ having two objects, which we will denote by $M$ and $R^k$, with mapping spaces given by the formulas

$$\text{Map}_{\mathcal{C}_M}(R^k, R^k) = \text{Emb}(R^k, R^k)$$

$$\text{Map}_{\mathcal{C}_M}(R^k, M) = \text{Emb}(R^k, M)$$

$$\text{Map}_{\mathcal{C}_M}(M, R^k) = \emptyset$$

$$\text{Map}_{\mathcal{C}_M}(M, M) = \{\text{id}_M\}.$$ 

We identify the Kan complex $\text{BTop}(k)$ with a full subcategory of the nerve $\text{N}(\mathcal{C}_M)$. Let $B_M$ denote the Kan complex $\text{BTop}(k) \times_{\text{N}(\mathcal{C}_M)} \text{N}(\mathcal{C}_M)/M$. We let $\mathbb{E}_M^\otimes$ denote the $\infty$-operad $\text{BTop}(k)^\otimes \times_{\text{BTop}(k)^\mu} B_M^\mu$. In other words, we let $\mathbb{E}_M^\otimes$ denote the $\infty$-operad $\mathbb{E}_{BM}^\otimes$ of Definition 5.4.2.10.

Remark 5.4.5.2. Let $M$ be a topological manifold of dimension $k$, and let $B_M$ be defined as in Definition 5.4.5.1. Then $\mathbb{E}_M^\otimes$ can be obtained as the assembly of a $B_M$-family of $\infty$-operads, each of which is equivalent to $\mathbb{E}_k^\otimes$ (Remark 5.4.2.13). To justify our notation, we will show that the Kan complex $B_M$ is canonically homotopy equivalent to the (singular complex of) $M$. More precisely, we will construct a canonical chain of homotopy equivalences $B_M \leftarrow B_M' \rightarrow B_M'' \leftarrow \text{Sing}(M)$.

To this end, we define topological categories $\mathcal{C}_M'$ and $\mathcal{C}_M''$, each of which consists of a pair of objects $\{R^k, M\}$ with morphism spaces given by the formulas

$$\text{Map}_{\mathcal{C}_M'}(R^k, R^k) = \text{Emb}_0(R^k, R^k)$$

$$\text{Map}_{\mathcal{C}_M'}(R^k, M) = \text{Emb}(R^k, M)$$

$$\text{Map}_{\mathcal{C}_M'}(R^k, R^k) = \{0\}$$

$$\text{Map}_{\mathcal{C}_M'}(R^k, M) = M$$

$$\text{Map}_{\mathcal{C}_M''}(M, R^k) = \emptyset = \text{Map}_{\mathcal{C}_M''}(M, M)$$

$$\text{Map}_{\mathcal{C}_M''}(M, M) = \{\text{id}_M\} = \text{Map}_{\mathcal{C}_M''}(M, M).$$

Here we let $\text{Emb}_0(R^k, R^k)$ denote the closed subset of $\text{Emb}(R^k, R^k)$ spanned by those open embeddings $f : R^k \rightarrow R^k$ such that $f(0) = 0$.

Let $\text{BTop}'(k)$ denote the full subcategory of $\text{N}(\mathcal{C}_M')$ spanned by the object $R^k$, let $B_M'$ denote the fiber product $\text{BTop}(k) \times_{\text{N}(\mathcal{C}_M')} \text{N}(\mathcal{C}_M')/M$, and let $B_M''$ denote the fiber product $\{R^k\} \times_{\text{N}(\mathcal{C}_M'')} \text{N}(\mathcal{C}_M')/M$. We have maps of topological categories $\mathcal{C}_M \xrightarrow{\theta} \mathcal{C}_M' \xleftarrow{\psi} \mathcal{C}_M''$. The map $\theta$ is a weak equivalence of topological categories, and so induces a homotopy equivalence $B_M' \rightarrow B_M$. We claim that the induced map $\psi : B_M' \rightarrow B_M''$ is also a homotopy equivalence. We can identify vertices of $B_M'$ with open embeddings $R^k \rightarrow M$ and vertices of $B_M''$ with points of $M$; since $M$ is a $k$-manifold, the map $\psi$ is surjective on vertices. Fix a vertex $(j : R^k \hookrightarrow M) \in B_M'$. We have a map of homotopy fiber sequences

$$\text{Map}_{\mathcal{N}(\mathcal{C}_M')}(R^k, R^k) \rightarrow \text{Map}_{\mathcal{N}(\mathcal{C}_M')}(R^k, M) \xrightarrow{\phi} B_M'$$

$$\text{Map}_{\mathcal{N}(\mathcal{C}_M'')}\big(\text{Map}_{\mathcal{N}(\mathcal{C}_M')}(R^k, R^k) \rightarrow \text{Map}_{\mathcal{N}(\mathcal{C}_M')}(R^k, M) \xrightarrow{\phi} B_M' \big) \rightarrow B_M''.$$

It follows from Remark 5.4.11 that the left square is a homotopy pullback. It follows that the map of path spaces $\text{Map}_{B_M}(j, j') \rightarrow \text{Map}_{B_M'}(\psi(j), \psi(j'))$ is a homotopy equivalence for every $j'$ lying in the essential image of $\phi$. Since the space $\text{BTop}'(k)$ is connected, the map $\phi$ is essentially surjective, so that $\psi$ is a homotopy equivalence as desired.

We note there is a canonical homotopy equivalence $\text{Sing}(M) \rightarrow B_M''$ (adjoint to the weak homotopy equivalence appearing in Proposition T.2.2.2.7). Consequently, we obtain a canonical isomorphism $B_M \simeq B_M' \simeq B_M'' \simeq \text{Sing}(M)$ in the homotopy category $\mathcal{H}$. It follows that $\mathbb{E}_M^\otimes$ can be identified with the colimit of a diagram $\infty$-operads parametrized by $M$, each of which is equivalent to $\mathbb{E}_k^\otimes$. This family is generally not constant: instead, it is twisted by the principal $\text{Top}(k)$-bundle given by the tangent bundle of $M$. In other words, if $\mathcal{C}^\otimes$ is an $\infty$-operad, then we can think of an object of $\text{Alg}_{\mathbb{E}_M}(\mathcal{C})$ as a (twisted) family of $\mathbb{E}_k$-algebra objects of $\mathcal{C}^\otimes$, parametrized by the points of $M$.

CHAPTER 5. LITTLE CUBES AND FACTORIZABLE SHEAVES
5.4. LITTLE CUBES AND MANIFOLD TOPOLOGY

Example 5.4.5.3. Let $M$ be the Euclidean space $\mathbb{R}^k$. Then the Kan complex $B_M$ is contractible, so that $\mathbb{E}_M^\circ$ is equivalent to the little cubes operad $\mathbb{E}_k^\circ$ (see Example 5.4.2.15). Since the $\infty$-operad $\mathbb{E}_M^\circ$ depends functorially on $M$, we obtain another description of the “action up to homotopy” of the homeomorphism group $\text{Top}(k)$ on $\mathbb{E}_k^\circ$ (at least if we view $\text{Top}(k)$ as a discrete group).

Example 5.4.5.4. Let $M$ be a $k$-manifold which is given as a disjoint union of open submanifolds $M', M'' \subseteq M$. Then there is a canonical isomorphism of $\infty$-operads $\mathbb{E}_M^\circ \simeq \mathbb{E}_{M'}^\circ \boxtimes \mathbb{E}_{M''}^\circ$. Using Theorem 2.2.3.6, we deduce that the canonical map $\text{Alg}_{\mathbb{E}_M^\circ}(\mathcal{C}) \to \text{Alg}_{\mathbb{E}_{M'}^\circ}(\mathcal{C}) \times \text{Alg}_{\mathbb{E}_{M''}^\circ}(\mathcal{C})$ is an equivalence, for any $\infty$-operad $\mathcal{C}^\circ$.

Example 5.4.5.5. Let $M$ be a $k$-manifold and let $M'$ be a $k'$-manifold. There is an evident map of Kan complexes $\phi : B_M \times B_{M'} \to B_{M \times M'}$, which induces a bifunctor of $\infty$-operads $\theta : \mathbb{E}_M^\circ \times \mathbb{E}_{M'}^\circ \to \mathbb{E}_{M \times M'}^\circ$.

Remark 5.4.5.2 implies that $\phi$ is a homotopy equivalence, so that $\theta$ exhibits $\mathbb{E}_{M \times M'}^\circ$ as a tensor product of the $\infty$-operads $\mathbb{E}_M^\circ$ and $\mathbb{E}_{M'}^\circ$ (see Remark 5.4.2.14).

We now introduce a more rigid variant of the $\infty$-operad $\mathbb{E}_M^\circ$.

Definition 5.4.5.6. Let $M$ be a topological manifold of dimension $k$. Let $\text{Disk}(M)$ denote the collection of all open subsets $U \subseteq M$ which are homeomorphic to Euclidean space $\mathbb{R}^k$. We regard $\text{Disk}(M)$ as a partially ordered set (with respect to inclusions of open sets), and let $\text{N}(\text{Disk}(M))$ denote its nerve. Let $\text{N}(\text{Disk}(M))^\circ$ denote the subcategory subset of $\text{N}(\text{Disk}(M))^\Pi$ spanned by those morphisms $(U_1, \ldots, U_m) \to (V_1, \ldots, V_n)$ with the following property: for every pair of distinct integers $1 \leq i, j \leq m$ having the same image $k \in \langle n \rangle^\circ$, the open subsets $U_i, U_j \subseteq V_k$ are disjoint.

Remark 5.4.5.7. Let $M$ be a manifold of dimension. Then $\text{N}(\text{Disk}(M))^\circ$ is the $\infty$-operad associated to the ordinary colored operad $\mathcal{O}$ whose objects are elements of $\text{Disk}(M)$, with morphisms given by

$$\text{Mul}_\mathcal{O}([U_1, \ldots, U_n], V) = \begin{cases} * & \text{if } U_1 \cup \ldots \cup U_n \subseteq V \text{ and } U_i \cap U_j = \emptyset \text{ for } i \neq j \\ \emptyset & \text{otherwise.} \end{cases}$$

In particular, $\text{N}(\text{Disk}(M))^\circ$ is an $\infty$-operad (see Example 2.1.1.21).

Remark 5.4.5.8. Let $\text{Disk}(M)'$ denote the category whose objects are open embeddings $\mathbb{R}^k \hookrightarrow M$, and whose morphisms are commutative diagrams

$$\begin{array}{ccc}
\mathbb{R}^k \\ f \downarrow & \searrow f \\
M & \searrow & \mathbb{R}^k
\end{array}$$

where $f$ is an open embedding. Then the forgetful functor $(j : \mathbb{R}^k \hookrightarrow M) \mapsto j(\mathbb{R}^k)$ determines an equivalence of categories from $\text{Disk}(M)'$ to $\text{Disk}(M)$. If we regard $\text{Disk}(M)$ as a colored operad via the construction of Remark 5.4.5.7, then $\text{Disk}(M)'$ inherits the structure of a colored operad, to which we can associate an $\infty$-operad $\text{N}(\text{Disk}(M)')^\circ$ equipped with an equivalence $\phi : \text{N}(\text{Disk}(M)')^\circ \to \text{N}(\text{Disk}(M))^\circ$. The forgetful functor $(j : \mathbb{R}^k \hookrightarrow M) \mapsto \mathbb{R}^k$ determines a map of colored operads from $\text{Disk}(M)'$ to $\mathbb{E}_{\text{BTop}(k)}^\circ$. Passing to nerves, we obtain a map of $\infty$-operads $\text{N}(\text{Disk}(M)')^\circ \to \text{BTop}(k)^\circ$, which naturally factors through the map $\mathbb{E}_M^\circ \to \text{BTop}(k)^\circ$. Composing with a homotopy inverse to $\phi$, we get a map of $\infty$-operads $\text{N}(\text{Disk}(M))^\circ \to \mathbb{E}_M^\circ$.

We can describe the situation roughly as follows: the objects of the $\infty$-operads $\text{N}(\text{Disk}(M))^\circ$ and $\mathbb{E}_M^\circ$ are the same: copies of Euclidean space $\mathbb{R}^k$ equipped with an embedding in $M$. However, the morphisms
are slightly different: an $n$-ary operation in $E^\otimes_M$ is a diagram of open embeddings
\[
\prod_{1 \leq i \leq n} \mathbb{R}^k \rightarrow \mathbb{R}^k \\
\downarrow \\
M
\]
which commutes up to (specified) isotopy, while an $n$-ary operation in $N(Disk(M))^\otimes$ is given by a diagram as above which commutes on the nose.

The map of $\infty$-operads $\psi : N(Disk(M))^\otimes \rightarrow E^\otimes_M$ appearing in Remark 5.4.5.8 is not an equivalence. For example, the underlying $\infty$-category of $E^\otimes_M$ is the Kan complex $B_M \simeq Sing(M)$, while the underlying $\infty$-category of $N(Disk(M))^\otimes$ is the nerve of the partially ordered set $Disk(M)$, which is certainly not a Kan complex. However, this is essentially the only difference: the map $\psi$ exhibits $E^\otimes_M$ as the $\infty$-operad obtained from $N(Disk(M))^\otimes$ by inverting each of the morphisms in $Disk(M)$. More precisely, we have the following result:

**Theorem 5.4.5.9.** Let $M$ be a manifold and let $\mathcal{C}^\otimes$ be an $\infty$-operad. Composition with the map
\[
N(Disk(M))^\otimes \rightarrow E^\otimes_M
\]
of Remark 5.4.5.8 induces a fully faithful embedding $\theta : Alg_{E^\otimes_M}(\mathcal{C}) \rightarrow Alg_{N(Disk(M))^\otimes}(\mathcal{C})$. The essential image of $\theta$ is the full subcategory of $Alg_{N(Disk(M))^\otimes}(\mathcal{C})$ spanned by the locally constant $N(Disk(M))^\otimes$-algebra objects of $\mathcal{C}$ (see Definition 4.2.4.1).

Theorem 5.4.5.9 is an immediate consequence of Proposition 2.3.4.5, together with the following pair of lemmas:

**Lemma 5.4.5.10.** Let $M$ be a manifold of dimension $k$. Then the map $N(Disk(M))^\otimes \rightarrow E^\otimes_M$ induces a weak homotopy equivalence $\psi : N(Disk(M)) \rightarrow B_M$.

**Lemma 5.4.5.11.** The map of $\infty$-operads $Disk(M)^\otimes \rightarrow E^\otimes_M$ is a weak approximation to $E^\otimes_M$.

**Proof of Lemma 5.4.5.10.** The construction $U \mapsto B_U$ determines a functor $\chi$ from the category $Disk(M)$ to the category of simplicial sets. Let $X$ denote the relative nerve $N_X(Disk(M))$ (see §T.3.2.5), so that we have a coCartesian fibration $\theta : X \rightarrow N(Disk(M))$ whose over an object $U \in Disk(M)$ is the Kan complex $B_U$. Remark 5.4.5.2 implies that the fibers of $\theta$ are contractible, so that $\theta$ is a trivial Kan fibration. The projection map $\theta$ has a section $s$, which carries an object $U \in Disk(M)$ to a chart $\mathbb{R}^k \simeq U$ in $B_U$. The map $\psi$ is obtained by composing the section $s$ with the evident map $\psi' : X \rightarrow B_M$. Consequently, it will suffice to show that the map $\psi'$ is a weak homotopy equivalence. According to Proposition T.3.3.4.5, this is equivalent to the requirement that $B_M$ be a colimit of the diagram $\{U \mapsto B_U\}_{U \in Disk(M)}$ in the $\infty$-category of spaces $\mathcal{S}$. Using Remark 5.4.5.2 again, we may reduce to showing that $Sing M$ is a colimit of the diagram $\{U \mapsto Sing U\}_{U \in Disk(M)}$. In view of Theorem A.3.1, we need only show that for every point $x \in M$, the partially ordered set $P : \{U \in Disk(M) : x \in U\}$ is weakly contractible. In fact, $P^{op}$ is filtered: for every finite collection of open disks $U_i \subseteq M$ containing $x$, the intersection $\bigcap_i U_i$ is an open neighborhood of $x$ which contains a smaller open neighborhood $V \simeq \mathbb{R}^k$ of $x$ (because $M$ is a topological manifold).

**Proof of Lemma 5.4.5.11.** Since the map $E^\otimes_M \rightarrow BTop(k)^\otimes$ is an approximation (Remark 5.4.2.11), it will suffice to show that the composite map
\[
\gamma : N(Disk(M))^\otimes \rightarrow E^\otimes_M \rightarrow BTop(k)^\otimes
\]
is a weak approximation to $BTop(k)^\otimes$. To this end, fix an object $U \in Disk(M)$ and an integer $m \geq 0$; wish to prove that the map
\[
\psi : N(Disk(M))^\otimes_{/U} \times_{N(\mathcal{F}in_{/\bullet}(1))} \{\langle m \rangle\} \rightarrow BTop(k)^\otimes_{/U} \times_{N(\mathcal{F}in_{/\bullet}(1))} \{\langle m \rangle\}
\]
is a weak homotopy equivalence (Corollary 2.3.3.16). We can identify the domain of \( \psi \) with the nerve \( N(A) \), where \( A \subseteq \text{Disk}(M)^m \) denotes the partially ordered set of sequences \( (V_1, \ldots, V_m) \in \text{Disk}(M)^m \) such that \( \bigcup V_i \subseteq U \) and \( V_i \cap V_j = \emptyset \) for \( i \neq j \).

It will now suffice to show that \( \psi \) induces a homotopy equivalence after passing to the homotopy fiber over the unique vertex of the Kan complex \( \text{BTop}(k)^m \). Unwinding the definitions, we must show that the canonical map

\[
\hocolim_{(V_1, \ldots, V_m) \in A} \prod_{1 \leq i \leq m} \text{Sing Emb}(\mathbb{R}^k, V_i) \to \text{Sing Emb}(\mathbb{R}^k \times \langle m \rangle^\circ, U)
\]

is a weak homotopy equivalence. Using Proposition 5.4.1.8, we can reduce to showing instead that the map

\[
\hocolim_{(V_1, \ldots, V_m) \in A} \prod_{1 \leq i \leq m} \text{Germ}(V_i) \to \text{Germ}(\langle m \rangle^\circ, U)
\]

is a homotopy equivalence. Both sides are acted on freely by the simplicial group \( \text{Germ}_0(\mathbb{R}^k) \). Consequently, it will suffice to show that we obtain a weak homotopy equivalence of quotients

\[
\hocolim_{(V_1, \ldots, V_m) \in A} \prod_{1 \leq i \leq m} \text{Conf}(\{i\}, V_i) \to \text{Conf}(\langle m \rangle^\circ, U).
\]

In view of Theorem A.3.1, it will suffice to show that for every injective map \( \phi : \langle m \rangle^\circ \to U \), the partially ordered set \( A_\phi = \{(V_1, \ldots, V_m) \in A : \phi(i) \in V_i\} \) has weakly contractible nerve. This is clear, since \( A_\phi^\circ \) is filtered (because each point \( \phi(i) \) has arbitrarily small neighborhoods homeomorphic to Euclidean space \( \mathbb{R}^k \)).

We can summarize Theorem 5.4.5.9 informally as follows. To give an \( E_M \)-algebra object \( A \) of a symmetric monoidal \( \infty \)-category \( \mathcal{C} \), we need to specify the following data:

(i) For every open disk \( U \subseteq M \), an object \( A(U) \in \mathcal{C} \).

(ii) For every collection of disjoint open disks \( V_1, \ldots, V_n \) contained in an open disk \( U \subseteq M \), a map \( A(V_1) \otimes \cdots \otimes A(V_n) \to A(U) \), which is an equivalence when \( n = 1 \).

In §5.5.1, we will explain how to describe this data in another way: namely, as a cosheaf on the Ran space of \( M \) (see Definition 5.5.1.1). However, in the setting of the Ran space, it is much more convenient to work with a \( \text{nonunital} \) version of the theory of \( E_M \)-algebras. Consequently, we will spend the remainder of this section explaining how to adapt the above ideas to the nonunital case. We associate to every \( k \)-manifold \( M \) an \( \infty \)-operad \( (E_k^\circ)^{\text{nu}}_M \) as in Definition 5.4.4.1. It follows from Remark 2.3.3.9 and Proposition 2.3.4.8 that \( (E_k^\circ)^{\text{nu}}_M \) is the assembly of the \( B_M \)-family of \( \infty \)-operads \( (B_M \times N(\text{Fin}_*) \times \mu^k_{BM} (E_k^\circ))^\text{nu}_M \), each fiber of which is equivalent to the nonunital little cubes operad \( (E_k^\circ)^\text{nu} \). If \( \mathcal{C}^\circ \) is a symmetric monoidal \( \infty \)-category, we let \( \text{Alg}_{E_M}(\mathcal{C}) \) denote the \( \infty \)-category \( \text{Alg}_{(E_M)^{\text{nu}}}(\mathcal{C}) \) of nonunital \( E_M \)-algebra objects of \( \mathcal{C} \). Our next goal is to show that the results of §5.4.4 can be generalized to the present setting: that is, for any symmetric monoidal \( \infty \)-category \( \mathcal{C} \), we can identify \( \text{Alg}_{E_M}(\mathcal{C}) \) with a subcategory of \( \text{Alg}_{E_M^{\text{nu}}}(\mathcal{C}) \) (Proposition 5.4.5.14). Our first step is to identify the relevant subcategory more precisely.

**Definition 5.4.5.12.** If \( \mathcal{C}^\circ \) is a symmetric monoidal \( \infty \)-category and \( M \) is a manifold of dimension \( k > 0 \), we will say that a nonunital \( E_M \)-algebra object \( A \in \text{Alg}_{E_M^{\text{nu}}}(\mathcal{C}) \) is \emph{quasi-unital} if, for every point \( U \in B_M \), the restriction of \( A \) to the fiber \( \{(U) \times N(\text{Fin}_*) \times \mu^k_{BM} (E_k^\circ)^{\text{nu}}_M \simeq (E_k^\circ)^{\text{nu}}_M \} \) determines a quasi-unital \( E_k \)-algebra object of \( \mathcal{C} \), in the sense of Definition 5.4.4.2. Similarly, we will say that a map \( f : A \to B \) of quasi-unital \( E_M \)-algebra objects of \( \mathcal{C} \) is \emph{quasi-unital} if its restriction to each fiber \( \{(U) \times N(\text{Fin}_*) \times \mu^k_{BM} (E_k^\circ)^{\text{nu}}_M \} \) determines a quasi-unital map of nonunital \( E_k \)-algebras. We let \( \text{Alg}_{E_M^{\text{nu}}}(\mathcal{C}) \) denote the subcategory of \( \text{Alg}_{E_M}^{\text{nu}}(\mathcal{C}) \) spanned by the quasi-unital \( E_M \)-algebra objects of \( \mathcal{C} \) and quasi-unital morphisms between them.
Remark 5.4.5.13. Let $M$ be a manifold of dimension $k > 0$ and let $A$ be a nonunital $E_M$-algebra object of a symmetric monoidal $\infty$-category $\mathcal{C}^{\otimes}$. Fix a point $U \in B_M$, corresponding to an open embedding $\psi : \mathbb{R}^k \hookrightarrow M$. We will say that a map $u : 1 \to A(U)$ in $\mathcal{C}$ is a quasi-unit for $A$ if, for every pair of objects $V,W \in B_M$ and every morphism $\phi : U \otimes V \to W$, the composite map

$$A(V) \simeq 1 \otimes A(V) \xrightarrow{\Delta} A(U) \otimes A(V) \to A(W)$$

is homotopic to the map induced by the composition $U \to U \otimes V \xrightarrow{\Delta} W$ in $E_M$. Note that it suffices to check this condition in the special case where $V = W = U$ and, if $k > 1$, where $\phi$ is a single map (arbitrarily chosen). Unwinding the definition, we see that $A$ is quasi-unital if and only if there exists a quasi-unit $u : 1 \to A(U)$ for each $U \in B_M$. Similarly, a map $A \to B$ between quasi-unital $E_M$-algebra objects is quasi-unital if, for every quasi-unit $u : 1 \to A(U)$, the composite map $1 \to A(U) \to B(U)$ is a quasi-unit for $B$. Moreover, if $M$ is connected, then it suffices to check these conditions for a single $U \in B_M$.

Proposition 5.4.5.14. Let $M$ be a manifold of dimension $k > 0$ and let $\mathcal{C}^{\otimes}$ be a symmetric monoidal $\infty$-category. Then the restriction functor $\text{Alg}_{E_M}(\mathcal{C}) \to \text{Alg}_{E_M}^{nu}(\mathcal{C})$ is an equivalence of $\infty$-categories.

Proof. For every map of simplicial sets $K \to B_M$, let $\mathcal{O}^{\otimes}_K$ denote the $K$-family of $\infty$-operads

$$(K \times N(\text{Fin}_n)) \times B_M \otimes E_M$$

and set $\mathcal{O}^{\otimes}_{\mathcal{C},K} = (K \times N(\text{Fin}_n)) \times B_M \otimes (E_M^{\otimes})_{nu}$. Note that the projection map $q : \mathcal{O}^{\otimes}_K \to K$ is a coCartesian fibration. Let $\text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}(\mathcal{C})$ denote the full subcategory of $\text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}(\mathcal{C})$ spanned by those $\infty$-operad maps which carry $q$-coCartesian morphisms to equivalences in $\mathcal{C}$, let $\text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}(\mathcal{C})$ be defined similarly, and let $\text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}^{nu}(\mathcal{C})$ denote the subcategory of $\text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}(\mathcal{C})$ spanned by those objects which restrict to quasi-unital $\mathcal{O}^{\otimes}_K \otimes (\mathcal{E}_{\mathcal{C}})^{\otimes}_{nu}$-algebra objects of $\mathcal{C}$ and those morphisms which restrict to quasi-unital $\mathcal{O}^{\otimes}_{\mathcal{C},K} \otimes (\mathcal{E}_{\mathcal{C}})^{\otimes}_{nu}$-algebra maps for every vertex $v \in K$. There is an evident restriction map $\theta_K : \text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}(\mathcal{C}) \to \text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}^{nu}(\mathcal{C})$ fitting into a commutative diagram

$$\begin{array}{ccc}
\text{Alg}_{E_M}(\mathcal{C}) & \longrightarrow & \text{Alg}_{E_M}^{nu}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}(\mathcal{C}) & \longrightarrow & \text{Alg}_{\mathcal{O}^{\otimes}_{\mathcal{C},K}}^{nu}(\mathcal{C}).
\end{array}$$

If $K = B_M$, then the vertical maps are categorical equivalences. Consequently, it will suffice to prove that $\theta_K$ is an equivalence for every map of simplicial sets $K \to B_M$. The collection of simplicial sets $K$ which satisfy this condition is clearly stable under homotopy colimits; we can therefore reduce to the case where $K$ is a simplex, in which case the desired result follows from Theorem 5.4.4.5.

It follows from Lemma 5.4.5.11 and Remark 2.3.3.9 that for every manifold $M$, the map $\text{Disk}(M)^{\otimes}_{nu} \to (E_M^{\otimes})_{nu}$ is a weak approximation to $(E_M^{\otimes})_{nu}$. Combining this with Lemma 5.4.5.10 and Theorem 2.3.3.23, we deduce the following nonunital variant of Theorem 5.4.5.9:

Proposition 5.4.5.15. Let $M$ be a manifold and let $\mathcal{C}^{\otimes}$ be an $\infty$-operad. Then composition with map $N(\text{Disk}(M))^{\otimes} \to E_M$ of Remark 5.4.5.8 induces a fully faithful embedding

$$\theta : \text{Alg}_{E_M}^{nu}(\mathcal{C}) \to \text{Alg}_{N(\text{Disk}(M))}^{nu}(\mathcal{C}).$$

The essential image of $\theta$ is the full subcategory of $\text{Alg}_{N(\text{Disk}(M))}^{nu}(\mathcal{C})$ spanned by the locally constant objects.

Definition 5.4.5.16. Let $M$ be a manifold of dimension $k > 0$ and let $\mathcal{C}^{\otimes}$ be a symmetric monoidal $\infty$-category. We will say that a locally constant $\text{Disk}(M)^{\otimes}_{nu}$-algebra object of $\mathcal{C}$ is quasi-unital if it corresponds to a quasi-unital $(E_M^{\otimes})_{nu}$-algebra object of $\mathcal{C}$ under the equivalence of Proposition 5.4.5.15. Similarly, we
will say that a map \( f : A \to B \) between locally constant quasi-unital \( \text{Disk}(M)^\otimes \)-algebra objects of \( \mathcal{C} \) is quasi-unital if it corresponds to a quasi-unital morphism in \( \text{Alg}^\text{nu}_{\text{Disk}(M)}(\mathcal{C}) \) under the equivalence of Proposition 5.4.5.15. We let \( \text{Alg}^\text{nu,loc}_{\text{Disk}(M)}(\mathcal{C}) \) denote the subcategory of \( \text{Alg}^\text{nu}_{\text{Disk}(M)}(\mathcal{C}) \) spanned by the quasi-unital, locally constant \( \text{Disk}(M)^\otimes \)-algebra objects of \( \mathcal{C} \) and quasi-unital morphisms between them.

**Remark 5.4.5.17.** Let \( A \in \text{Alg}^\text{nu,loc}_{\text{Disk}(M)}(\mathcal{C}) \), let \( W \in \text{Disk}(M) \) be an open disk in \( M \), and let \( U \subseteq W \) be an open disk with compact closure in \( W \). We say that a map \( 1 \to A(U) \) in \( \mathcal{C} \) is a quasi-unit for \( A \) if, for every disk \( V \in \text{Disk}(M) \) such that \( V \subseteq W \) and \( V \cap U = \emptyset \), the diagram

\[
1 \otimes A(V) \xrightarrow{n \otimes \text{id}} A(U) \otimes A(V) \\
\downarrow \quad \downarrow \\
A(V) \quad \longrightarrow \quad A(W)
\]

commutes up to homotopy. Note that if \( M \) has dimension at least 2, it suffices to check this condition for a single open disk \( V \). Unwinding the definition, we see that \( A \) is quasi-unital if and only if there exists a quasi-unit \( n : 1 \to A(U) \) for every pair \( U \subseteq W \) as above, and a map \( f : A \to B \) in \( \text{Alg}^\text{nu,loc}_{\text{Disk}(M)}(\mathcal{C}) \) is quasi-unital if and only if composition with \( f \) carries every quasi-unit \( 1 \to A(U) \) to a quasi-unit \( 1 \to B(U) \) (see Remark 5.4.5.13). In fact, it suffices to check these conditions for a single pair \( U \subseteq W \) in each connected component of \( M \).

Combining Proposition 5.4.5.14, Theorem 5.4.5.9, and Proposition 5.4.5.15, we arrive at the following:

**Proposition 5.4.5.18.** Let \( M \) be a manifold of dimension \( k > 0 \) and \( \mathcal{C}^\otimes \) a symmetric monoidal \( \infty \)-category. Then the restriction functor \( \text{Alg}^\text{loc,nu}_{\text{Disk}(M)}(\mathcal{C}) \to \text{Alg}^\text{nu,loc}_{\text{Disk}(M)}(\mathcal{C}) \) is an equivalence of \( \infty \)-categories.

In other words, there is no essential loss of information in passing from unital \( \text{Disk}(M)^\otimes \)-algebras to nonunital \( \text{Disk}(M)^\otimes \)-algebras, at least in the locally constant case. For this reason, we will confine our attention to nonunital algebras in §5.5.

### 5.5 Topological Chiral Homology

Let \( M \) be a topological manifold, and let \( \mathbb{E}_M^\otimes \) be the \( \infty \)-operad introduced in Definition 5.4.5.1. Roughly speaking, we can think of an \( \mathbb{E}_M \)-algebra \( A \) object of a symmetric monoidal \( \infty \)-category \( \mathcal{C}^\otimes \) as a family of \( \mathbb{E}_k \)-algebras \( A_x \) parametrized by the points \( x \in M \) (more accurately, one should think of this family as “twisted” by the tangent bundle of \( M \); that is, for every point \( x \in M \) we should think of \( A_x \) as an algebra over an \( \infty \)-operad whose objects are little disks in the tangent space \( T_{M,x} \) to \( M \) at \( x \)).

There is a convenient geometric way to encode this information. We define the Ran space \( \text{Ran}(M) \) of \( M \) to be the collection of all nonempty finite subsets of \( M \) (for a more detailed discussion of \( \text{Ran}(M) \), including a description of the topology on \( \text{Ran}(M) \), we refer the reader to 5.5.1). To every point \( S \in \text{Ran}(M) \), the tensor product \( A_S = \bigotimes_{x \in S} A_x \) is an object of \( \mathcal{C} \). We will see that these objects are the stalks of a \( \mathcal{C} \)-valued cosheaf \( \mathcal{F} \) on the Ran space. We can regard \( \mathcal{F} \) as a constructible cosheaf which is obtained by gluing together locally constant cosheaves along the locally closed subsets \( \text{Ran}^n(M) = \{ S \in \text{Ran}(M) : |S| = n \} \subseteq \text{Ran}(M) \) for \( n \geq 1 \); the “gluing” data for these restrictions reflects the multiplicative structure of the algebras \( \{ A_x \}_{x \in M} \).

In §5.5.4, we will see that the construction \( A \to \mathcal{F} \) determines an equivalence of \( \infty \)-categories from the \( \infty \)-category of \( \mathcal{C} \)-valued cosheaves on \( \text{Ran}(M) \), which are constructible with respect to the above stratification (Theorem 5.5.4.10).

The description of an \( \mathbb{E}_M \)-algebra object \( A \) of \( \mathcal{C} \) as a factorizable \( \mathcal{C} \)-valued cosheaf \( \mathcal{F} \) on \( \text{Ran}(M) \) suggests an interesting invariant of \( A \): namely, the object \( \mathcal{F}(\text{Ran}(M)) \in \mathcal{C} \) given by global sections of \( \mathcal{F} \). In the case where \( M \) is connected, we will refer to the global sections \( \mathcal{F}(\text{Ran}(M)) \) as the topological chiral homology of \( M \) with coefficients in \( A \), which we will denote by \( \int_M A \). We will give an independent definition of \( \int_M A \).
(which does not require the assumption that \( M \) is connected) in §5.5.2, and verify that it is equivalent to \( \mathcal{F}(\text{Ran}(M)) \) for connected \( M \) in §5.5.4 (Theorem 5.5.4.14). The construction \( A \mapsto \int_M A \) can be regarded as a generalization of Hochschild homology (Theorem 5.5.3.11) and has a number of excellent formal properties, which we will discuss in §5.5.3.

In §5.5.6, we will use the theory of topological chiral homology to formulate and prove a nonabelian version of the Poincare duality theorem (Theorem 5.5.6.6). The proof will rely on general version of Verdier duality (Theorem 5.5.5.4), which we prove in §5.5.5.

**Remark 5.5.0.1.** We will regard Convention 5.4.0.1 as in force throughout this section: the word manifold will always refer to a paracompact, Hausdorff, topological manifold of some fixed dimension \( k \).

### 5.5.1 The Ran Space

**Definition 5.5.1.1.** Let \( M \) be a manifold. We let \( \text{Ran}(M) \) denote the collection of nonempty finite subsets \( S \subseteq M \). We will refer to \( \text{Ran}(M) \) as the Ran space of \( M \).

The Ran space \( \text{Ran}(M) \) admits a natural topology, which we will define in a moment. Our goal in this section is to study the basic properties of \( \text{Ran}(M) \) as a topological space. Our principal results are Theorem 5.5.1.6, which asserts that \( \text{Ran}(M) \) is weakly contractible (provided that \( M \) is connected), and Proposition 5.5.1.14, which characterizes sheaves on \( \text{Ran}(M) \) which are constructible with respect to the natural filtration of \( \text{Ran}(M) \) by cardinality of finite sets.

Our first step is to define the topology on \( \text{Ran}(M) \). First, we need to introduce a bit of notation. Suppose that \( \{U_i\}_{1 \leq i \leq n} \) is a nonempty collection of pairwise disjoint subsets of \( M \). We let \( \text{Ran}(\{U_i\}) \subseteq \text{Ran}(M) \) denote the collection of finite sets \( S \subseteq M \) such that \( S \subseteq \bigcup U_i \) and \( S \cap U_i \) is nonempty for \( 1 \leq i \leq n \).

**Definition 5.5.1.2.** Let \( M \) be a manifold. We will regard the Ran space \( \text{Ran}(M) \) as equipped with the coarsest topology for which the subsets \( \text{Ran}(\{U_i\}) \subseteq \text{Ran}(M) \) are open, for every nonempty finite collection of pairwise disjoint open sets \( \{U_i\} \) of \( M \).

**Remark 5.5.1.3.** If \( \{U_i\} \) is a nonempty finite collection of pairwise disjoint open subsets of a manifold \( M \), then the open subset \( \text{Ran}(\{U_i\}) \subseteq \text{Ran}(M) \) is homeomorphic to a product \( \prod \text{Ran}(U_i) \), via the map \( \{S_i \subseteq U_i\} \mapsto (\bigcup S_i \subseteq M) \).

**Remark 5.5.1.4.** Let \( M \) be a manifold, and let \( S = \{x_1, \ldots, x_n\} \) be a point of \( \text{Ran}(M) \). Then \( S \) has a basis of open neighborhoods in \( \text{Ran}(M) \) of the form \( \text{Ran}(\{U_i\}) \), where the \( U_i \) range over all collections of disjoint open neighborhoods of the points \( x_i \) in \( M \). Since \( M \) is a manifold, we may further assume that that each \( U_i \) is homeomorphic to Euclidean space.

**Remark 5.5.1.5.** If we choose a metric \( d \) on the manifold \( M \), then the topology on \( \text{Ran}(M) \) is described by a metric \( D \), where

\[
D(S,T) = \sup_{s \in S} \inf_{t \in T} d(s,t) + \sup_{t \in T} \inf_{s \in S} d(s,t).
\]

It follows that \( \text{Ran}(M) \) is paracompact.

Our first main object in this section is to prove the following result of Beilinson and Drinfeld:

**Theorem 5.5.1.6** (Beilinson-Drinfeld). Let \( M \) be a connected manifold. Then \( \text{Ran}(M) \) is weakly contractible.

We first formulate a relative version of Theorem 5.5.1.6 which is slightly easier to prove.

**Notation 5.5.1.7.** Let \( M \) be a manifold and \( S \) a finite subset of \( M \). We let \( \text{Ran}(M)_S \) denote the closed subset of \( \text{Ran}(M) \) consisting of those nonempty finite subsets \( T \subseteq \text{Ran}(M) \) such that \( S \subseteq T \).

**Lemma 5.5.1.8** (Beilinson-Drinfeld). Let \( M \) be a connected manifold and let \( S \) be a nonempty finite subset of \( M \). Then \( \text{Ran}_S(M) \) is weakly contractible.
5.5. **TOPOLOGICAL CHIRAL HOMOLOGY**

Proof: We first prove that $\text{Ran}(M)_S$ is path connected. Let $T$ be a subset of $M$ containing $S$. For each $t \in T$, choose a path $p_t : [0, 1] \to M$ such that $p_t(0) = t$ and $p_t(1) \in S$ (this is possible since $M$ is connected and $S$ is nonempty). Then the map $r \mapsto S \cup \{p_t(r)\}_{t \in T}$ determines a continuous path in $\text{Ran}(M)_S$ joining $T$ with $S$. We will complete the proof by showing that for each $n > 0$, every element $\eta \in \pi_n \text{Ran}(M)_S$ is trivial; here we compute the homotopy group $\pi_n$ with respect to the base point given by $S \in \text{Ran}(M)_S$.

The topological space $\text{Ran}(M)_S$ admits a continuous product $U : \text{Ran}(M)_S \times \text{Ran}(M)_S \to \text{Ran}(M)_S$, given by the formula $U(T, T') = T \cup T'$. This product induces a map of homotopy groups

$$\phi : \pi_n \text{Ran}(M)_S \times \pi_n \text{Ran}(M)_S \to \pi_n \text{Ran}(M)_S.$$  

Since $S$ is a unit with respect to the multiplication on $\text{Ran}(M)_S$, we conclude that $\phi(\eta, 1) = \eta = \phi(1, \eta)$ (where we let 1 denote the unit element of the homotopy group $\pi_n \text{Ran}(M)_S$). Because the composition of the diagonal embedding $\text{Ran}(M)_S \to \text{Ran}(M)_S \times \text{Ran}(M)_S$ with $U$ is the identity from $\text{Ran}(M)_S$ to itself, we have also $\phi(\eta, \eta) = \eta$. It follows that

$$\eta = \phi(\eta, \eta) = \phi(\eta, 1)\phi(1, \eta) = \eta^2$$

so that $\eta = 1$ as desired. \hfill \Box

**Proof of Theorem 5.5.1.6.** For every point $x \in M$, choose an open embedding $j_x : \mathbb{R}^k \hookrightarrow M$ such that $j_x(0) = x$. Let $U_x = j_x(B(1))$ be the image under $j_x$ of the unit ball in $\mathbb{R}^k$, and let $V_x$ be the open subset of $\text{Ran}(M)$ consisting of those nonempty finite subsets $S \subseteq M$ such that $S \cap U_x \neq \emptyset$. Let $\mathcal{J}$ be the partially ordered set of all nonempty finite subsets of $M$ (that is, $\mathcal{J}$ is the Ran space $\text{Ran}(M)$, but viewed as a partially ordered set). We define a functor from $\mathcal{J}^{op}$ to the category of open subsets of $\text{Ran}(M)$ by the formula

$$T \mapsto V_T = \bigcap_{x \in T} V_x.$$  

For each $S \in \text{Ran}(M)$, the partially ordered set $\{T \in \mathcal{J} : S \subseteq V_T\}$ is nonempty and stable under finite unions, and therefore has weakly contractible nerve. It follows that $\text{Sing} \text{Ran}(M)$ is equivalent to the homotopy colimit of the diagram $\{\text{Sing} V_T\}_{T \in \mathcal{J}^{op}}$ (Theorem A.3.1). We will prove that each of the spaces $V_T$ is weakly contractible, so that this homotopy colimit is weakly homotopy equivalent to $\text{N}(\mathcal{J}^{op})$ and therefore weakly contractible.

Fix $T \in \mathcal{J}$, and choose a continuous family of maps $\{h_r : \mathbb{R}^k \to \mathbb{R}^k\}_{0 \leq r \leq 1}$ with the following properties:

(i) For $0 \leq r \leq 1$, the map $h_r$ is the identity outside of a ball $B(2) \subseteq \mathbb{R}^k$ of radius 2.

(ii) The map $h_0$ is the identity.

(iii) The map $h_1$ carries $B(1) \subseteq \mathbb{R}^k$ to the origin.

We now define a homotopy $\phi_T : \text{Ran}(M) \times [0, 1] \to \text{Ran}(M)$ by the formula

$$\phi_T(S, r) = S \cup \bigcup_{x \in T} j_x h_t j_x^{-1}(S).$$

The homotopy $\phi_T$ leaves $V_T$ and $\text{Ran}(M)_T$ setwise fixed, and carries $V_T \times \{1\}$ into $\text{Ran}(M)_T$. It follows that the inclusion $\text{Ran}(M)_T \subseteq V_T$ is a homotopy equivalence, so that $V_T$ is weakly contractible by Lemma 5.5.1.8. \hfill \Box

We now discuss a natural stratification of the Ran space.

**Definition 5.5.1.9.** Let $M$ be a manifold. We let $\text{Ran}^\leq n(M)$ denote the subspace of $\text{Ran}(M)$ consisting of those subsets $S \subseteq M$ having cardinality $\leq n$, and $\text{Ran}^n(M)$ the subspace of $\text{Ran}^\leq n(M)$ consisting of those subsets $S \subseteq M$ having cardinality exactly $n$. 

Remark 5.5.1.10. The set $\text{Ran}^{\leq n}(M)$ is closed in $\text{Ran}(M)$, and $\text{Ran}^n(M)$ is open in $\text{Ran}^{\leq n}(M)$.

Definition 5.5.1.11. Let $M$ be a manifold and let $\mathcal{F} \in \text{Shv}(\text{Ran}(M))$ be a sheaf on $\text{Ran}(M)$. For each $n \geq 0$, let $i(n) : \text{Ran}^{\leq n}(M) \to \text{Ran}(M)$ denote the inclusion map. We will say that $\mathcal{F}$ is constructible if the following conditions are satisfied:

1. The canonical map $\mathcal{F} \to \varinjlim_n i(n)_* i(n)^* \mathcal{F}$ is an equivalence.
2. For each $n$, the restriction of $i(n)^* \mathcal{F}$ to the open subset $\text{Ran}^n(M) \subseteq \text{Ran}^{\leq n}(M)$ is locally constant.

Remark 5.5.1.12. Condition (2) of Definition 5.5.1.11 is equivalent to the requirement that $\mathcal{F}$ be $\mathbb{Z}_{\geq 0}$-constructible, where we regard $\text{Ran}(M)$ as $\mathbb{Z}_{\geq 0}$-stratified via the map $\text{Ran}(M) \to \mathbb{Z}_{\geq 0}$ given by $S \mapsto |S|$. We refer the reader to §5.4.1 for a general review of the theory of constructible sheaves. Here we are required to impose condition (1) because the partially ordered set $\mathbb{Z}_{\geq 0}$ does not satisfy the ascending chain condition.

Remark 5.5.1.13. We can endow the topological space $\text{Ran}(M)$ with another topology, where a set $U \subseteq \text{Ran}(M)$ is open if and only if its intersection with each $\text{Ran}^{\leq n}(M)$ is open (with respect to the topology of Definition 5.5.1.1). If $\mathcal{F}$ is a sheaf on $\text{Ran}(M)$ with respect to this second topology, then condition (1) of Definition 5.5.1.11 is automatic: this follows from Proposition T.7.1.5.8.

The following result gives a convenient characterization of constructible sheaves on the Ran space:

Proposition 5.5.1.14. Let $M$ be a manifold and $\mathcal{F} \in \text{Shv}(\text{Ran}(M))$. Then $\mathcal{F}$ is constructible if and only if it is hypercomplete and satisfies the following additional condition:

(*) For every nonempty finite collection of disjoint disks $U_1, \ldots, U_n \subseteq M$ containing open subdisks $V_1 \subseteq U_1, \ldots, V_n \subseteq U_n$, the restriction map $\mathcal{F}(\text{Ran}(|U_i|)) \to \mathcal{F}(\text{Ran}(|V_i|))$ is a homotopy equivalence.

Proof. We first prove the “only if” direction. Suppose that $\mathcal{F}$ is constructible. To show that $\mathcal{F}$ is hypercomplete, we write $\mathcal{F}$ as a limit $\varinjlim i(n)_* i(n)^* \mathcal{F}$ as in Definition 5.5.1.11. It therefore suffices to show that each $i(n)^* \mathcal{F}$ is hypercomplete. This follows from the observation that $\text{Ran}^{\leq n}(M)$ is a paracompact topological space of finite covering dimension (Corollary T.7.2.1.12).

We now prove every constructible sheaf $\mathcal{F} \in \text{Shv}(\text{Ran}(M))$ satisfies (*). For $1 \leq i \leq n$, we invoke Theorem 5.4.1.5 to choose an isotopy $\{h^i_t : V_i \to U_i\}_{t \in \mathbb{R}}$ such that $h^0_0$ is the inclusion of $V_i$ into $U_i$ and $h^1_1$ is a homeomorphism. These isotopies determine an open embedding

$$H : \text{Ran}(|V_i|) \times \mathbb{R} \to \text{Ran}(|U_i|) \times \mathbb{R}.$$ 

Let $\mathcal{F}' \in \text{Shv}(\text{Ran}(|U_i|) \times \mathbb{R})$ be the pullback of $\mathcal{F}$, so that $\mathcal{F}'$ is hypercomplete (see Lemma A.2.6 and Example A.2.8). It follows that $H^* \mathcal{F}'$ is hypercomplete. Since $\mathcal{F}$ is constructible, we deduce that $\mathcal{F}'$ is foliated. For $t \in \mathbb{R}$, let $\mathcal{F}'_t$ denote the restriction of $\mathcal{F}$ to $\text{Ran}(|V_i|) \times \{t\}$. We have a commutative diagram of spaces

$$\begin{array}{ccc}
\mathcal{F}(\text{Ran}(|U_i|)) & \xrightarrow{\theta} & \mathcal{F}'((\text{Ran}(|V_i|) \times \mathbb{R}) \\
\downarrow \theta' & & \downarrow \theta'' \\
\mathcal{F}'_t(\text{Ran}(|V_i|)) & \xrightarrow{} & \mathcal{F}'_t((\text{Ran}(|V_i|) \times \mathbb{R})
\end{array}$$

Since each $h^1_1$ is a homeomorphism, we deduce that $\theta'$ is a homotopy equivalence. Proposition A.2.5 guarantees that $\theta''$ is a homotopy equivalence, so that $\theta$ is a homotopy equivalence by the two-out-of-three property. Applying Proposition A.2.5 again, we deduce that the composite map $\mathcal{F}(\text{Ran}(|U_i|)) \to \mathcal{F}_0(\text{Ran}(|V_i|)) \cong \mathcal{F}(\text{Ran}(|V_i|))$ is a homotopy equivalence as desired.

We now prove the “if” direction of the proposition. Assume that $\mathcal{F}$ is hypercomplete and that $\mathcal{F}$ satisfies (*); we wish to prove that $\mathcal{F}$ is constructible. We first show that the restriction of $\mathcal{F}$ to each $\text{Ran}^n(M)$ is locally constant. Choose a point $S \in \text{Ran}^n(M)$; we will show that $\mathcal{F}|_{\text{Ran}^n(M)}$ is constant in a neighborhood of $S$. 
Let $S = \{x_1, \ldots, x_n\}$, and choose disjoint open disks $U_1, \ldots, U_n \subseteq X$ such that $x_i \in U_i$. Let $W \subseteq \text{Ran}^n(M)$ denote the collection of all subsets $S \subseteq M$ which contain exactly one point from each $U_i$. We will prove that $\mathcal{F}|\text{Ran}^n(M)$ is constant on $W$. Let $X = \mathcal{F}(\text{Ran}(\{U_i\}))$. Since $W \subseteq \text{Ran}(\{U_i\})$, there is a canonical map from the constant sheaf on $W$ taking the value $X$ to $\mathcal{F}|W$; we will show that this map is an equivalence. Since $W \simeq U_1 \times \ldots \times U_n$ is a manifold, it has finite covering dimension so that $\text{Shv}(W)$ is hypercomplete. Consequently, to show that a morphism in $\text{Shv}(W)$ is an equivalence, it suffices to check after passing to the stalk at each point $\{y_1, \ldots, y_n\} \in W$. This stalk is given by $\lim_{\rightarrow V} \mathcal{F}(V)$, where the colimit is taken over all open subsets $V \subseteq \text{Ran}(M)$ containing $\{y_1, \ldots, y_n\}$. It follows from Remark 5.5.1.4 that it suffices to take the colimit over those open sets $V$ of the form $\text{Ran}(\{V_i\})$, where each $V_i \subseteq U_i$ is an open neighborhood of $y_i$. Condition (1) guarantees that each of the maps $X \to \mathcal{F}(V)$ is a homotopy equivalence, so after passing to the filtered colimit we obtain a homotopy equivalence $X \to \lim_{\rightarrow V} \mathcal{F}(V)$ as desired.

Let $\mathcal{S} = \varprojlim_n i(n)^* \mathcal{F}$ (using the notation of Definition 5.5.1.11). To complete the proof, it will suffice to show that the canonical map $\alpha : \mathcal{F} \to \mathcal{S}$ is an equivalence. Since each $i(n)^* \mathcal{F}$ is automatically hypercomplete (because $\text{Ran}^{\leq n}(M)$ is a paracompact space of finite covering dimension), we see that $\mathcal{S}$ is hypercomplete. Using the results of §1.6.5.3, we deduce that the collection of those open sets $U \subseteq \text{Ran}(M)$ such that $\alpha$ induces a homotopy equivalence $\alpha_U : \mathcal{F}(U) \to \mathcal{S}(U)$ is stable under the formation of unions of hypercoverings. It therefore suffices to show that $\alpha_U$ is an homotopy equivalence for some collection of open sets $U$ which forms a basis for the topology of $\text{Ran}(M)$. By virtue of Remark 5.5.1.4, we may assume that $U = \text{Ran}(\{U_i\})$ for some collection of disjoint open disks $U_1, \ldots, U_n$.

For each integer $m$, let $\mathcal{F}^{\leq m} = i(m)^* \mathcal{F}$. We wish to prove that the map $\mathcal{F}(U) \to \lim_{\rightarrow m} \mathcal{F}^{\leq m}(U \cap \text{Ran}^{\leq m}(M))$ is a homotopy equivalence. In fact, we will prove that the individual maps $\mathcal{F}(U) \to \mathcal{F}^{\leq m}(U \cap \text{Ran}^{\leq m}(M))$ are homotopy equivalences for $m \geq n$. Choose a point $x_i$ in each disk $U_i$, and let $S = \{x_1, \ldots, x_n\}$. Let $\mathcal{F}_S$ denote the stalk of $\mathcal{F}$ at the point $S$. We have a commutative diagram of restriction maps

$$
\begin{array}{ccc}
\mathcal{F}(U) & \to & \mathcal{F}^{\leq m}(U \cap \text{Ran}^{\leq m}(M)) \\
\phi \downarrow & & \phi' \downarrow \\
\mathcal{F}_S & \to & \mathcal{F}_S
\end{array}
$$

where $\phi$ is a homotopy equivalence by the argument given above. By the two-out-of-three property, we are reduced to proving that $\phi'$ is a homotopy equivalence.

The set $U \cap \text{Ran}^{\leq m}(M)$ admits a stratification by the linearly ordered set $[m]$, which carries a point $T \in \text{Ran}(M)$ to the cardinality of $T$. Let $\mathcal{C} = \text{Sing}^{[m]}(U \cap \text{Ran}^{\leq m}(M))$. Since $\mathcal{F}$ is constructible, the sheaf $\mathcal{F}|(U \cap \text{Ran}^{\leq m}(M))$ corresponds to some left fibration $q : \mathcal{C} \to \mathcal{C}$ under the equivalence of $\infty$-categories provided by Theorem A.9.3. Under this equivalence, we can identify $\mathcal{F}^{\leq m}(U \cap \text{Ran}^{\leq m}(M))$ with the $\infty$-category $\text{Fun}_{\mathcal{C}}(\mathcal{C}, \mathcal{C})$ of sections of $q$, while $\mathcal{F}_S$ corresponds to the fiber of $\mathcal{C}_S$ of $q$ over the point $S \in \mathcal{C}$. To prove that $\theta'$ is an equivalence, it suffices to show that $S$ is an initial object of $\mathcal{C}$. To this end, choose homeomorphisms $\psi_i : \mathbb{R}^k \to U_i$ for $1 \leq i \leq n$ such that $\psi_i(0) = x_i$. We then have a map

$$
c : [0, 1] \times (U \cap \text{Ran}^{\leq m}(M)) \to (U \cap \text{Ran}^{\leq m}(M))
$$

given by the formula $c(t, T) = \{\psi_i(tv) : \psi_i(v) \in T\}$. The continuous map $c$ induces a natural transformation from the inclusion $\{S\} \to \mathcal{C}$ to the identity functor from $\mathcal{C}$ to itself, thereby proving that $S \in \mathcal{C}$ is initial as desired.

To apply Proposition 5.5.1.14, it is convenient to have the following characterization of hypercompleteness:

**Proposition 5.5.1.15.** Let $X$ be a topological space, $\mathcal{U}(X)$ the collection of open subsets of $X$, and $\mathcal{F} : \mathbb{N}(\mathcal{U}(X)^{op}) \to \mathcal{S}$ a presheaf on $X$. The following conditions are equivalent:

1. The presheaf $\mathcal{F}$ is a hypercomplete sheaf on $X$. 

(2) Let \( U \) be an open subset of \( X \), \( E \) be a category, and \( f : \mathcal{C} \to \mathcal{U}(U) \) a functor. Suppose that, for every point \( x \in U \), the full subcategory \( \mathcal{C}_x = \{ C \in \mathcal{C} : x \in f(C) \} \subseteq \mathcal{C} \) has weakly contractible nerve. Then \( \mathcal{F} \) exhibits \( \mathcal{F}(U) \) as a limit of the diagram \( N(\mathcal{C})^{op} \to N(\mathcal{U}(X)^{op}) \xrightarrow{\mathcal{F}} S \).

Lemma 5.5.1.16. Let \( X \) be a topological space, and let \( \mathcal{F} \in \text{Shv}(X) \) be an \( \infty \)-connective sheaf satisfying the following condition:

\[ (*) \quad \text{Let } A \text{ be a partially ordered set and } f : A \to \mathcal{U}(X)^{op} \text{ an order-preserving map such that, for every point } x \in X, \text{ the full subcategory } A_x = \{ a \in A : x \in f(a) \} \subseteq A \text{ is filtered. Then } \mathcal{F} \text{ exhibits } \mathcal{F}(X) \text{ as a limit of the diagram } N(A) \to N(\mathcal{U}(X)^{op}) \xrightarrow{\mathcal{F}} S. \]

Then the space \( \mathcal{F}(X) \) is nonempty.

Proof. The functor \( \mathcal{F} : N(\mathcal{U}(X)^{op}) \to S \) classifies a left fibration \( q : \mathcal{E} \to N(\mathcal{U}(X)^{op}) \). We will construct a partially ordered set \( A \) and a map \( \psi : N(A) \to \mathcal{E} \) such that the composite map \( N(A) \to N(\mathcal{U}(X)^{op}) \) and each subset \( A_x \) is filtered. According to Corollary T.3.3.3.3, we can identify the limit \( \lim_{\leftarrow a \in A} \mathcal{F}(f(a)) \) with the Kan complex \( \text{Fun}_{N(\mathcal{U}(X)^{op})}(N(A), \mathcal{E}) \), which is nonempty by construction.

We will construct a sequence of partially ordered sets

\[ \emptyset = A(0) \subseteq A(1) \subseteq \ldots \]

and compatible maps \( \psi(n) : N(A(n)) \to \mathcal{E} \) with the following properties:

(i) For every element \( a \in A(n) \), the set \( \{ b \in A(n) : b < a \} \) is a finite subset of \( A(n-1) \).

(ii) For every point \( x \in X \) and every finite subset \( S \subseteq A(n-1)_x \), there exists an upper bound for \( S \) in \( A(n)_x \).

Assuming that this can be done, we can complete the proof by taking \( A = \bigcup_n A(n) \) and \( \psi \) be the amalgamation of the maps \( \psi(n) \).

The construction now proceeds by induction on \( n \). Assume that \( n > 0 \) and that the map \( \psi(n-1) : N(A(n-1)) \to \mathcal{E} \) has already been constructed. Let \( K \) be the set of pairs \((x,S)\), where \( x \in X \) and \( S \) is a finite subset of \( A(n-1)_x \) which is closed-downwards (that is, \( a \leq a' \) and \( a' \in S \) implies \( a \in S \)). We define \( A(n) \) to be the disjoint union \( A(n-1) \coprod K \). We regard \( A(n) \) as a partially ordered set, where \( a < b \) in \( A(n) \) if and only if \( a, b \in A(n-1) \) and \( a < b \) in \( A(n-1), \) or \( a \in A(n-1), b = (x,S) \in K, \) and \( a \in S \). It is clear that \( A(n) \) satisfies condition (i). It remains only to construct a map \( \psi(n) : N(A(n)) \to \mathcal{E} \) which extends \( \psi(n-1) \) and satisfies (ii). Unwinding the definitions, we must show that for every pair \((x,S)\in K\), the extension problem

\[
\begin{array}{ccc}
N(S) & \xrightarrow{\psi'} & \mathcal{E} \\
\downarrow{\phi} & & \\
N(S)^{op} & & \\
\end{array}
\]

admits a solution, where \( \psi' \) denotes the restriction \( \psi(n-1)|_{N(S)} \) and \( \phi \) carries the cone point of \( N(S)^{op} \) to an object \( E \in \mathcal{E} \) such that \( x \in q(E) \in \mathcal{U}(X) \).

Since \( S \) is finite, the subset \( U = \bigcap_{s \in S} q(\psi'(s)) \) is an open subset of \( X \) containing the point \( x \). The map \( \psi' \) determines a diagram \( \alpha : N(S) \to \mathcal{E} \times_{N(\mathcal{U}(X)^{op})}\{U\} \simeq \mathcal{F}(U) \). To prove the existence of \( \phi \), it suffices to show that there exists a smaller open subset \( V \subseteq U \) containing \( x \) such that the composite map \( N(S) \to \mathcal{F}(U) \to \mathcal{F}(V) \) is nullhomotopic. Since \( N(S) \) is finite, it suffices to show \( \alpha \) induces a nullhomotopic map from \( N(S) \) into the stalk \( \mathcal{F}_x = \lim_{x \in V} \mathcal{F}(V) \). We conclude by observing that \( \mathcal{F}_x \) is contractible (since \( \mathcal{F} \) is assumed to be \( \infty \)-connective). \( \square \)
5.5. TOPOLOGICAL CHIRAL HOMOLOGY 723

Proof of Proposition 5.5.1.15. Suppose first that (1) is satisfied; we will verify (2). Let \( \chi : \mathcal{U}(X) \to \text{Shv}(X) \) be the functor which carries an open set \( U \) to the sheaf \( \chi_U \) given by the formula

\[
\chi_U(V) = \begin{cases} 
\Delta^0 & \text{if } V \subseteq U \\
\emptyset & \text{otherwise.}
\end{cases}
\]

Let \( \mathcal{G} = \varprojlim_{C \in e} \chi_f(C) \). For every point \( x \in U \), the stalk \( \mathcal{G}_x \) is weakly homotopy equivalent to the nerve of the category \( \mathcal{E}_x \), and for \( x \not\in U \) the stalk \( \mathcal{G}_x \) is empty. If each \( \mathcal{E}_x \) has weakly contractible nerve, then we conclude that the canonical map \( \mathcal{G} \to \chi_U \) is \( \infty \)-connective, so that

\[ \mathcal{F}(U) \simeq \text{Map}_{\text{Shv}(X)}(\chi_U, \mathcal{F}) \simeq \text{Map}_{\text{Shv}(X)}(\mathcal{G}, \mathcal{F}) \simeq \varprojlim_{\mathcal{C} \in e} \text{Map}_{\text{Shv}(X)}(\chi_f(C), \mathcal{F}) = \varprojlim_{\mathcal{C} \in e} \mathcal{F}(f(C)). \]

Now suppose that (2) is satisfied. Let \( S \subseteq \mathcal{U}(X) \) be a covering sieve on an open set \( U \subseteq X \). Then for each \( x \in U \), the partially ordered set \( S_x = \{ V \in S : x \in V \} \) is nonempty and stable under finite intersections, so that \( N(S_x)^{op} \) is filtered and therefore weakly contractible. It follows from (2) that the map \( \mathcal{F}(U) \to \varprojlim_{V \in S} \mathcal{F}(V) \) is a homotopy equivalence, so that \( \mathcal{F} \) is a sheaf. It remains to show that \( \mathcal{F} \) is hypercomplete. Choose an \( \infty \)-connective morphism \( \alpha : \mathcal{F} \to \mathcal{F}' \), where \( \mathcal{F}' \) is hypercomplete; we wish to show that \( \alpha \) is an equivalence. The first part of the proof shows that \( \mathcal{F}' \) also satisfies the condition stated in (2). Consequently, it will suffice to prove the following:

(*) Let \( \alpha : \mathcal{F} \to \mathcal{G} \) be an \( \infty \)-connective morphism in \( \text{Shv}(X) \), where \( \mathcal{F} \) and \( \mathcal{G} \) both satisfy (2). Then \( \alpha \) is an equivalence.

To prove (*), it suffices to show that for each open set \( U \subseteq X \), \( \alpha \) induces a homotopy equivalence \( \alpha_U : \mathcal{F}(U) \to \mathcal{G}(U) \). We will show that \( \alpha_U \) is \( n \)-connective for each \( n \geq 0 \), using induction on \( n \). If \( n = 0 \), then we can conclude by applying the inductive hypothesis to the diagonal map \( \beta : \mathcal{F} \to \mathcal{F} \times_{\mathcal{G}} \mathcal{F} \). It remains to consider the case \( n = 0 \); that is, to show that the map \( \alpha_U \) is surjective on connected components. In other words, we must show that every map \( \chi_U \to \mathcal{G} \) factors through \( \alpha \). This follows by applying Lemma 5.5.1.16 to the fiber product \( \chi_U \times_{\mathcal{G}} \mathcal{F} \) (and restricting to the open set \( U \)).

5.5.2 Topological Chiral Homology

Let \( M \) be a \( k \)-manifold and \( \mathcal{E}^\otimes \) a symmetric monoidal \( \infty \)-category. We can think of an \( \mathbb{E}_M \)-algebra \( A \in \text{Alg}_{\mathbb{E}_M}(\mathcal{E}) \) as a family of \( \mathbb{E}_k \)-algebras \( A_x \in \text{Alg}_{\mathbb{E}_k}(\mathcal{E}) \), parametrized by the points \( x \in M \). In this section, we will explain how to extract from \( A \) a global invariant \( f_M A \), which we call the topological chiral homology of \( M \) (with coefficients in \( A \)). Our construction is a homotopy-theoretic analogue of the Beilinson-Drinfeld theory of chiral homology for the chiral algebras of [14]. It is closely related to the notion of blob homology studied by Morrison and Walker ([112]).

The basic idea of the construction is simple. According to Theorem 5.4.5.9, we can think of an \( \mathbb{E}_M \)-algebra object \( A \) of a symmetric monoidal \( \infty \)-category \( \mathcal{C} \) as a functor which assigns to every disjoint union of open disks \( U \subseteq M \) an object \( A(U) \in \mathcal{C} \), which carries disjoint unions to tensor products. Our goal is to formally extend the definition of \( A \) to all open subsets of \( M \). Before we can give the definition, we need to establish some terminology.

Definition 5.5.2.1. Let \( M \) be a manifold and \( \mathcal{U}(M) \) the partially ordered set of all open subsets of \( M \). We can identify objects of the \( \infty \)-category \( N(\mathcal{U}(M))^{\text{Hil}} \) with finite sequences \( (U_1, \ldots, U_n) \) of open subsets of \( M \). We let \( N(\mathcal{U}(M))^{\otimes} \) denote the subcategory of \( N(\mathcal{U}(M))^{\text{Hil}} \) spanned by those morphisms \( (U_1, \ldots, U_n) \to (V_1, \ldots, V_m) \) which cover a map \( \alpha : (n) \to (m) \) in \( \text{Fin}_* \) and possess the following property: for \( 1 \leq j \leq m \), the sets \( \{ U_i \}_{\alpha(i) = j} \) are disjoint open subsets of \( V_j \).

For every manifold \( M \), the nerve \( N(\mathcal{U}(M))^{\otimes} \) is an \( \infty \)-operad which contains \( N(\text{Disk}(M))^{\otimes} \) as a full subcategory.
Definition 5.5.2.2. We will say that a symmetric monoidal ∞-category $\mathcal{C}^\otimes$ is sifted-complete if the underlying ∞-category $\mathcal{C}$ admits small sifted colimits and the tensor product functor $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small sifted colimits.

Remark 5.5.2.3. If a simplicial set $K$ is sifted, then the requirement that the tensor product $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserve sifted colimits is equivalent to the requirement that it preserve sifted colimits separately in each variable.

Example 5.5.2.4. Let $\mathcal{C}^\otimes$ be a symmetric monoidal ∞-category. Assume that the underlying ∞-category $\mathcal{C}$ admits small colimits, and that the tensor product on $\mathcal{C}$ preserves small colimits separately in each variable. Let $\mathcal{O}^\otimes$ be an arbitrary small ∞-operad, so that $\text{Alg}_{\mathcal{O}}(\mathcal{C})$ inherits a symmetric monoidal structure (given by pointwise tensor product). The ∞-category $\text{Alg}_{\mathcal{O}}(\mathcal{C})$ itself admits small colimits (Corollary 3.2.3.3), but the tensor product on $\text{Alg}_{\mathcal{O}}(\mathcal{C})$ generally does not preserve colimits in each variable. However, it does preserve sifted colimits separately in each variable: this follows from Proposition 3.2.3.1. Consequently, $\text{Alg}_{\mathcal{O}}(\mathcal{C})$ is a sifted-complete symmetric monoidal ∞-category.

The main existence result we will need is the following:

Theorem 5.5.2.5. Let $M$ be a manifold and let $q : \mathcal{C}^\otimes \to N(\text{Fin}_*)$ be a sifted-complete symmetric monoidal ∞-category. For every algebra object $A \in \text{Alg}_{S^M}(\mathcal{C})$, the restriction $A|_{N(\text{Disk}(M))}^\otimes$ admits an operadic left Kan extension to $N(\text{U}(M)^\otimes)$.

Assuming Theorem 5.5.2.5 for the moment, we can give the definition of topological chiral homology.

Definition 5.5.2.6. Let $M$ be a manifold and let $\mathcal{O}^\otimes$ be a sifted-complete symmetric monoidal ∞-category. We let $f : \text{Alg}_{S^M}(\mathcal{C}) \to \text{Alg}_{N(\text{U}(M))}(\mathcal{C})$ be the functor given by restriction to $N(\text{Disk}(M))^\otimes$ followed by operadic left Kan extension along the inclusion $N(\text{U}(M))^\otimes \to N(\text{U}(M)^\otimes)$. If $A \in \text{Alg}_{S^M}(\mathcal{C})$ and $U$ is an open subset of $M$, we will denote the value of $f(A)$ on the open set $U \subseteq M$ by $f_U A \in \mathcal{C}$. We will refer to $f_U A$ as the topological chiral homology of $U$ with coefficients in $A$.

Remark 5.5.2.7. To describe the content of Definition 5.5.2.6 more concretely, it is useful to introduce a bit of notation. If $M$ is a manifold, we let $\text{Disj}(M)$ denote the partially ordered subset of $\text{U}(M)$ spanned by those open subsets $U \subseteq M$ which are homeomorphic to $S \times \mathbb{R}^k$ for some finite set $S$. In the situation of Definition 5.5.2.6, the algebra object $A$ determines a functor $\theta : N(\text{Disj}(M)) \to \mathcal{C}$, given informally by the formula

$$V_1 \cup \cdots \cup V_n \mapsto A(V_1) \otimes \cdots \otimes A(V_n)$$

(here the $V_i$ denote pairwise disjoint open disks in $M$). The topological chiral homology $f_M A \in \mathcal{C}$ is then given by the colimit of the diagram $\theta$.

Example 5.5.2.8. Let $U \subseteq M$ be an open subset homeomorphic to Euclidean space. Then there is a canonical equivalence $A(U) \simeq f_U A$.

Remark 5.5.2.9. Suppose that we have a map of ∞-operads $\psi : E_M^\otimes \to \mathcal{O}^\otimes$, where $\mathcal{O}^\otimes$ is some other ∞-operad. Let $A \in \text{Alg}_{\mathcal{O}}(\mathcal{C})$. Then we will abuse notation by denoting the topological chiral homology $f_M(\psi \circ A)$ simply by $f_M A$. This abuse is consistent with the notation of Definition 4.8.3.5 in the following sense: if $A \in \text{Alg}_{S^M}(\mathcal{C})$, then the topological chiral homology $f_M A$ of $U$ with coefficients in $A$ is equivalent to the topological chiral homology $f_M(A|_{E_N^\otimes})$ of $U$ with coefficients in the induced $E_N$-algebra.

Example 5.5.2.10. Let $A \in \text{Alg}_{B_{\text{Top}}(k)}(\mathcal{C})$. Then Remark 5.5.2.9 allows us to define the topological chiral homology $f_M A$ of any $k$-manifold with coefficients in $A$. Similarly, if $A \in \text{Alg}_{S^{\text{sm}}}(\mathcal{C})$ (see Example 5.4.2.18), then $f_M A$ is defined for any smooth $k$-manifold $M$. Many other variations on this theme are possible: roughly speaking, if $A$ is an $E_k$-algebra object of $\mathcal{C}$ equipped with a compatible action of some group $G$ mapping to $\text{Top}(k)$, then $f_M A$ is well-defined if we are provided with a reduction of the structure group of $M$ to $G$. 

In order to prove Theorem 5.5.2.5 (and to establish the basic formal properties of topological chiral homology), we need to have good control over colimits indexed by partially ordered sets of the form $\text{Disj}(M)$, where $M$ is a manifold (see Remark 5.5.2.7). We will obtain this control by introducing a less rigid version of the $\infty$-category $\text{N}(\text{Disj}(M))$, where we allow open disks in $M$ to “move”.

**Definition 5.5.2.11.** Fix an integer $k \geq 0$. We let $\text{Man}(k)$ denote the topological category whose objects are $k$-manifolds, with morphism spaces given by $\text{Map}_{\text{Man}(k)}(N, M) = \text{Emb}(N, M)$. If $M$ is a $k$-manifold, we let $\mathbf{D}(M)$ denote the full subcategory of the $\infty$-category $\text{N}(\text{Man}(k))_{/M}$ spanned by those objects of the form $j : N \to M$, where $N$ is homeomorphic to $S \times \mathbb{R}^k$ for some finite set $S$.

**Remark 5.5.2.12.** An object of the $\infty$-category $\mathbf{D}(M)$ can be identified with a finite collection of open embeddings $\{\psi_i : \mathbb{R}^k \hookrightarrow M\}_{1 \leq i \leq n}$ having disjoint images. Up to equivalence, this object depends only on the sequence of images $\psi_1(\mathbb{R}^k), \ldots, \psi_n(\mathbb{R}^k)$, which we can identify with an object of the category $\text{Disj}(M)$. However, the morphisms in these two categories are somewhat different: a morphism in $\mathbf{D}(M)$ is given by a diagram

$$
\begin{array}{ccc}
\coprod_{1 \leq i \leq m} \mathbb{R}^k & \longrightarrow & \coprod_{1 \leq j \leq n} \mathbb{R}^k \\
\{\psi_i\} & \searrow & \{\psi_j\} \\
& M & 
\end{array}
$$

which commutes up to (specified) isotopy, which does not guarantee an inclusion of images $\bigcup \psi_i(\mathbb{R}^k) \subseteq \bigcup \psi_j(\mathbb{R}^k)$. Nevertheless, there is an evident functor $\gamma : \text{N}(\text{Disj}(M)) \to \mathbf{D}(M)$, defined by choosing a parametrization of each open disk in $M$ (up to equivalence, the functor $\gamma$ is independent of these choices).

The fundamental result we will need is the following:

**Proposition 5.5.2.13.** Let $M$ be a $k$-manifold. Then:

1. The functor $\gamma : \text{N}(\text{Disj}(M)) \to \mathbf{D}(M)$, described in Remark 5.5.2.12, is left cofinal.

2. Let $\text{Disj}(M)_{\text{nu}}$ denote the subcategory of $\text{Disj}(M)$ whose objects are nonempty open sets $U \in \text{Disj}(M)$ and whose morphisms are inclusions $U \hookrightarrow V$ such that the induced map $\pi_0 U \to \pi_0 V$ is surjective. If $M$ is connected, then the induced functor $\text{N}(\text{Disj}(M)_{\text{nu}}) \to \mathbf{D}(M)$ is left cofinal.

The second assertion of Proposition 5.5.2.13 will require the following technical result:

**Lemma 5.5.2.14.** Let $M$ be a connected manifold, let $S$ be a finite subset of $M$, and let $\text{Disj}(M)_{\text{nu}}^S$ denote the full subcategory of $\text{Disj}(M)_{\text{nu}}$ spanned by those objects $V \in \text{Disj}(M)_{\text{nu}}$ such that $S \subseteq V$. Then the simplicial set $\text{N}(\text{Disj}(M)_{\text{nu}}^S)$ is weakly contractible.

**Proof.** For every object $V \in \text{Disj}(M)_{\text{nu}}^S$, let $\psi(V)$ denote the subset of $\text{Ran}(M)$ consisting of those subsets $T$ with the following properties:

1. We have inclusions $S \subseteq T \subseteq V$.
2. The map $T \to \pi_0 V$ is surjective.

For every point $T \in \text{Ran}(M)_S$, let $\mathcal{C}_T$ denote the full subcategory of $\text{Disj}(M)_{\text{nu}}^S$ spanned by those objects $V$ such that $T \in \psi(V)$. Each of the category $\mathcal{C}_T$ is filtered (for every finite collection $V_1, \ldots, V_n \in \mathcal{C}_T$, we can choose $V \in \mathcal{C}_T$ such that $V \subseteq \bigcap V_i$ and each of the maps $\pi_0 V \to \pi_0 V_i$ is surjective: namely, take $V$ to be a union of sufficiently small open disks containing the points of $T$). It follows from Theorem A.3.1 that the Kan complex $\text{Sing} \text{Ran}(M)_S$ is equivalent to the homotopy colimit of the diagram $\{\psi(V)\}_{V \in \text{Disj}(M)_{\text{nu}}^S}$. For each $V \in \text{Disj}(M)_{\text{nu}}^S$, write $V$ as a disjoint union of open disks $U_1 \cup \ldots \cup U_m$. Then $\psi(V)$ is homeomorphic to a product $\prod_{1 \leq i \leq m} \text{Ran}(U_i)_{S \cap U_i}$, and is therefore weakly contractible by Lemmas 5.5.1.8 and 5.5.1.6. It follows that the Kan complex $\text{Sing} \text{Ran}(M)_S$ is weakly homotopy equivalent to the nerve of the category $\text{Disj}(M)_{\text{nu}}$. The desired result now follows from the weak contractibility of $\text{Sing} \text{Ran}(M)_S$ (Lemmas 5.5.1.8 and 5.5.1.6).
Proof of Proposition 5.5.2.13. We first give the proof of (1). Let \( S = \{1, \ldots, n\} \), let \( U = S \times \mathbb{R}^k \), and let \( \psi : U \to M \) be an open embedding corresponding to an object of \( \mathbf{D}(M) \). According to Theorem T.4.1.3.1, it will suffice to show that the \( \infty \)-category \( \mathcal{C} = N(\text{Disj}(M)) \times \mathbf{D}(M)_{M/} \) is weakly contractible. We observe that the projection map \( \mathcal{C} \to N(\text{Disj}(M)) \) is a left fibration, associated to a functor \( \chi : N(\text{Disj}(M)) \to \mathcal{S} \) which carries each object \( V \in \text{Disj}(M) \) to the homotopy fiber of the map of Kan complexes \( \text{Sing}\Emb(U, V) \to \text{Sing}\Emb(U, M) \). According to Proposition T.3.3.4.5, it will suffice to show that the colimit \( \lim \mathcal{C} \) is contractible. Since colimits in \( \mathcal{S} \) are universal, it will suffice to show that \( \text{Sing}\Emb(U, M) \) is a colimit of the diagram \( \{\text{Sing}\Emb(U, V)\}_{V \in \text{Disj}(M)} \). Using Proposition T.3.3.4.5, we can identify the weak homotopy type of \( \text{Sing}\Emb(U, M) \) with the colimit \( \lim \mathcal{C} \). Using Theorem T.6.1.3.9 and Remark 5.4.1.11, we are reduced to showing that \( \text{Sing}\Conf(S, M) \) is a colimit of the diagram \( \{\text{Sing}\Conf(S, V)\}_{V \in \text{Disj}(M)} \). According to Theorem A.3.1, it will suffice to show that for every injective map \( j : S \to M \), the partially ordered set \( \text{Disj}(M)_S = \{V \in \text{Disj}(M) : j(S) \subseteq V\} \) has weakly contractible nerve. This is clear, since \( \text{Disj}(M)_S \) is filtered: every open neighborhood of \( j(S) \) contains a union of sufficiently small open disks around the points \( \{j(s)\}_{s \in S} \). The proof of (2) is identical except for the last step: we must instead show that for every injective map \( j : S \to M \), the category \( \text{Disj}(M)^{\text{nu}}_S = \{V \in \text{Disj}(M)^{\text{nu}} : j(S) \subseteq V\} \) has weakly contractible nerve, which follows from Lemma 5.5.2.14. \( \square \)

The advantage of the \( \infty \)-category \( \mathbf{D}(M) \) over the more rigid \( \infty \)-category \( N(\text{Disj}(M)) \) is summarized in the following result:

**Proposition 5.5.2.15.** For every manifold \( M \), the \( \infty \)-category \( \mathbf{D}(M) \) is sifted.

For later use, it will be convenient to prove a slightly more general form of Proposition 5.5.2.15. Let \( \pi : \widetilde{M} \to M \) be a covering map between manifolds whose fibers are finite. Since any finite covering of a disk is homeomorphic to a disjoint union of disks, the construction \( U \mapsto \pi^{-1}U \) determines a functor \( \mathbf{D}(M) \to \mathbf{D}(\widetilde{M}) \). When \( \widetilde{M} = M \coprod M \), this can be identified with the diagonal map \( \mathbf{D}(M) \to \mathbf{D}(M) \times \mathbf{D}(M) \). Proposition 5.5.2.15 is therefore an immediate consequence of the following:

**Proposition 5.5.2.16.** Let \( \pi : \widetilde{M} \to M \) be a covering map between manifolds which has finite fibers. Then the induced map \( \pi^{-1} : \mathbf{D}(M) \to \mathbf{D}(\widetilde{M}) \) is left cofinal.

**Proof.** We have a commutative diagram

\[
\begin{array}{ccc}
\text{N(\text{Disj}(M))} & \to & \text{D}(\widetilde{M}) \\
\gamma & \downarrow \theta & \\
\text{D}(M) & \xrightarrow{\pi^{-1}} & \text{D}(\widetilde{M}),
\end{array}
\]

where \( \gamma \) is left cofinal by virtue of Proposition 5.5.2.13. It will therefore suffice to show that \( \theta \) is left cofinal (Proposition T.4.1.1.3). Fix an object \( \phi : U \to \widetilde{M} \) of \( \mathbf{D}(\widetilde{M}) \). According to Theorem T.4.1.3.1, it will suffice to show that the \( \infty \)-category \( \mathcal{C} = \mathbf{D}(\widetilde{M})_{\phi/} \times_{\mathbf{D}(\widetilde{M})} \text{N(\text{Disj}(M))} \) is weakly contractible. There is an evident left fibration \( \mathcal{C} \to \text{N(\text{Disj}(M))} \), classified by a functor \( \chi : \text{N(\text{Disj}(M))} \to \mathcal{S} \) which carries an object \( V \in \text{Disj}(M) \) to the homotopy fiber of the map

\[
\text{Sing}(\text{Emb}(U, \pi^{-1}V)) \to \text{Sing}(\text{Emb}(U, \widetilde{M}))
\]

over the vertex given by \( (\phi, \psi) \). Using Proposition T.3.3.4.5, we can identify the weak homotopy type of \( \mathcal{C} \) with the colimit \( \lim \mathcal{C} \). Consequently, it will suffice to show that \( \lim \mathcal{C} \) is contractible. Since colimits in \( \mathcal{S} \) are universal, it will suffice to show that \( \text{Sing}(\text{Emb}(U, \widetilde{M})) \) is a colimit of the diagram \( \chi' : \text{N(\text{Disj}(M))} \to \mathcal{S} \) given by the formula \( \chi'(V) = \text{Sing}(\text{Emb}(U, \pi^{-1}V)) \).

Let \( S \subseteq U \) be a set which contains on point from each connected component of \( U \) and let \( \chi'' : \text{N(\text{Disj}(M))} \to \mathcal{S} \) be the functor given by the formula \( V \mapsto \text{Sing}(\text{Conf}(S, \pi^{-1}V)) \). There is an evident
5.5. TOPOLOGICAL CHIRAL HOMOLOGY

restriction functor of diagrams \( \chi' \to \chi'' \). Using Remark 5.4.1.11 and Theorem T.6.1.3.9, we are reduced to proving that the canonical map \( \lim(\chi'') \to \text{Sing}(\text{Conf}(S, \bar{M})) \) is a homotopy equivalence. In view of Theorem A.3.1, it will suffice to show that for every point \( j \in \text{Conf}(S, \bar{M}) \) the full subcategory \( \text{Disj}(M)_j \) of \( \text{Disj}(M) \) spanned by those objects \( V \in \text{Disj}(M) \) such that \( j(S) \subseteq \pi^{-1}V \) is weakly contractible. This is clear, since \( \text{Disj}(M)^{op} \) is filtered.

Armed with Proposition 5.5.2.15, we are ready to prove that topological chiral homology is well-defined.

**Proof of Theorem 5.5.2.5.** According to Theorem 3.1.2.3, it will suffice to show that for each open set \( U \subseteq M \) the induced diagram

\[
\text{N}(\text{Disj}(U)) \xrightarrow{\theta} \text{D}(U) \xrightarrow{\beta} \mathbb{E}_M \xrightarrow{\Delta} \mathcal{C}^\otimes
\]

can be extended to an operadic colimit diagram in \( \mathcal{C}^\otimes \). Since \( \theta \) is left cofinal (Proposition 5.5.2.13), it suffices to show that \( A \circ \beta \) can be extended to an operadic colimit diagram in \( \mathcal{C}^\otimes \). Choose a \( q \)-coCartesian natural transformation from \( A \circ \beta \) to a functor \( \chi : \text{D}(U) \to \mathcal{C} \), given informally by the formula \( \chi(\{\psi_i : V_i \hookrightarrow U\}_{1 \leq i \leq n}) = A(\psi_1) \otimes \cdots \otimes A(\psi_n) \). In view of Proposition 3.1.1.15, it will suffice to show that \( \chi \) can be extended to an operadic colimit diagram in \( \mathcal{C} \). Since \( \text{D}(U) \) is sifted (Proposition 5.5.2.15) and the tensor product on \( \mathcal{C} \) preserves sifted colimits separately in each variable, it suffices to show that \( \chi \) can be extended to a colimit diagram in \( \mathcal{C} \) (Proposition 3.1.1.16). This colimit exists because \( \mathcal{C} \) admits sifted colimits and \( \text{D}(U) \) is sifted.

We close this section with the following result concerning the functorial behavior of topological chiral homology:

**Proposition 5.5.2.17.** Let \( M \) be a manifold, and let \( F : \mathcal{C}^\otimes \to \mathcal{D}^\otimes \) be a symmetric monoidal functor. Assume \( \mathcal{C}^\otimes \) and \( \mathcal{D}^\otimes \) are sifted-complete and that the underlying functor \( F : \mathcal{C} \to \mathcal{D} \) preserves sifted colimits. Then:

1. If \( A \in \text{Alg}_{\text{N}(\mathcal{U}(\mathcal{M}))(\mathcal{C})} \) has the property that \( A_0 = A| \text{N}(\text{Disk}(M))^\otimes \) is locally constant and \( A \) is an operadic left Kan extension of \( A_0 \), then \( FA \) is an operadic left Kan extension of \( FA_0 \).

2. For any locally constant algebra \( A \in \text{Alg}_{\text{Sing}(\text{Conf}(\mathcal{M}))(\mathcal{C})} \), the canonical map \( \int_M FA \to F(\int_M A) \) is an equivalence in \( \mathcal{C} \).

**Proof.** We first prove (1). Since \( A_0 \) is locally constant, we can assume that \( A_0 \) factors as a composition \( \text{N}(\text{Disk}(M))^\otimes \to \mathcal{E}_M \xrightarrow{A_0'} \mathcal{C}^\otimes \) (Theorem 5.4.5.9). We wish to prove that for every object \( U \in \mathcal{U}(\mathcal{M}) \), the diagram \( FA \) exhibits \( FA(U) \in \mathcal{D} \) as an operadic colimit of the composite diagram

\[
\text{Disj}(M) \xrightarrow{\alpha} \text{D}(M) \xrightarrow{\beta} \mathbb{E}_M \xrightarrow{A_0'} \mathcal{C}^\otimes \xrightarrow{F} \mathcal{D}^\otimes.
\]

Since \( \alpha \) is left cofinal (Proposition 5.5.2.13), it will suffice to show that \( FA \) exhibits \( FA(U) \) as an operadic colimit of \( F \circ A_0' \circ \beta \).

Let \( p : \mathcal{C}^\otimes \to \text{N}(\mathcal{F}\text{in}_\ast) \) exhibit \( \mathcal{C}^\otimes \) as a symmetric monoidal \( \infty \)-category, and let \( q : \mathcal{D}^\otimes \to \text{N}(\mathcal{F}\text{in}_\ast) \) exhibit \( \mathcal{D}^\otimes \) as a symmetric monoidal \( \infty \)-category. Choose a \( p \)-coCartesian natural transformation \( \alpha \) from \( A_0' \circ \beta \) to a map \( \phi : \text{D}(M) \to \mathcal{C} \). Since \( F \) is a symmetric monoidal functor, \( F(\alpha) \) is a \( q \)-coCartesian natural transformation from \( F \circ A_0' \circ \beta \) to \( F \circ \phi \). It will therefore suffice to show that \( FA \) exhibits \( FA(U) \) as a colimit of the diagram \( F \circ \phi \) in the \( \infty \)-category \( \mathcal{D} \) (Propositions 3.1.1.15 and 3.1.1.16). Since \( F|\mathcal{C} \) preserves sifted colimits and the \( \infty \)-category \( \text{D}(M) \) is sifted (Proposition 5.5.2.15), it suffices to show that \( A(U) \) is a colimit of the diagram \( \phi \). Using Propositions 3.1.1.15 and 3.1.1.16 again, we are reduced to proving that \( A(U) \) is an operadic colimit of the diagram \( A_0' \circ \beta \), which (since \( \alpha \) is left cofinal) follows from our assumption that \( A \) is an operadic left Kan extension of \( A_0 \). This completes the proof of (1). Assertion (2) is an immediate consequence.
5.5.3 Properties of Topological Chiral Homology

Our goal in this section is to establish four basic facts about the theory of topological chiral homology. In what follows, we will assume that \( \mathcal{E}^\circ \) is a sifted-complete symmetric monoidal \( \infty \)-category and \( M \) a topological manifold of dimension \( k \).

1. For a fixed algebra \( A \in \text{Alg}_{\mathbb{S}^k} (\mathcal{E}) \), the construction \( U \mapsto \int_U A \) carries disjoint unions of open subsets of \( M \) to tensor products in the \( \infty \)-category \( \mathcal{E} \) (Theorem 5.5.3.1).

2. For a fixed open set \( U \subseteq M \), the construction \( A \mapsto \int_U A \) carries tensor products of \( \mathbb{S}^k \)-algebra objects of \( \mathcal{E} \) to tensor products in \( \mathcal{E} \) (Theorem 5.5.3.2).

3. If \( A \in \text{Alg}_{\mathbb{S}^k} (\mathcal{E}) \) arises from a family \( \{ A_x \}_{x \in M} \) of commutative algebra objects of \( \mathcal{E} \), then \( \int_U A \) can be identified with image in \( \mathcal{E} \) of the colimit \( \lim_{x \in U} (A_x) \in C\text{Alg}(\mathcal{E}) \) (Theorem 5.5.3.8).

4. If \( k = 1 \) and \( M \) is the circle \( S^1 \), then we can view an algebra object \( A \in \text{Alg}_{\mathbb{S}^k} (\mathcal{E}) \) as an associative \( \mathcal{E} \)-algebra object of \( \mathcal{E} \) (equipped with an automorphism \( \theta \) given by monodromy around the circle). In this case, the topological chiral homology \( \int_M A \) can be identified with the \((\theta\text{-twisted})\) Hochschild homology of \( A \), which is computed by an analogue of the usual cyclic bar complex (Theorem 5.5.3.11).

We begin with assertion (1). The functor \( \int \) of Definition 5.5.2.6 carries \( \text{Alg}_{\mathbb{S}^k} (\mathcal{E}) \) into \( \text{Alg}_{\mathbb{S}^k ((\mathbb{S}^1 M))} (\mathcal{E}) \). Consequently, whenever \( U_1, \ldots, U_m \) are disjoint open subsets of \( U \subseteq M \), we have a multiplication map

\[
\int_{U_1} A \otimes \cdots \otimes \int_{U_m} A \to \int_U A.
\]

**Theorem 5.5.3.1.** Let \( M \) be a manifold and \( \mathcal{E}^\circ \) a sifted-complete symmetric monoidal \( \infty \)-category. Then for every object \( A \in \text{Alg}_{\mathbb{S}^k} (\mathcal{E}) \) and every collection of pairwise disjoint open subsets \( U_1, \ldots, U_m \subseteq M \), the map

\[
\int_{U_1} A \otimes \cdots \otimes \int_{U_m} A \to \int_{U_1} A
\]

is an equivalence in \( \mathcal{E} \).

**Proof.** It follows from Proposition 5.5.2.13 that for each open set \( U \subseteq M \), the topological chiral homology \( \int_U A \) is the colimit of a diagram \( \psi_U : D((U)) \to \mathcal{E} \) given informally by the formula \( \psi_U (V_1 \cup \ldots \cup V_n) = A(V_1) \otimes \cdots \otimes A(V_n) \). Since each \( D(U_i) \) is sifted (Proposition 5.5.2.15) and the tensor product on \( \mathcal{E} \) preserves sifted colimits separately in each variable, we can identify the tensor product \( \int_{U_1} A \otimes \cdots \otimes \int_{U_m} A \) with the colimit \( \lim_{\scriptstyle \to D(U_1) \times \cdots \times D(U_m)} (\psi_{U_1} \otimes \cdots \otimes \psi_{U_m}) \). Let \( W = \bigcup U_i \). The tensor product functor \( \psi_{U_1} \otimes \cdots \otimes \psi_{U_m} \) can be identified with the pullback of \( \psi_W \) along the evident map

\[
\alpha : D(U_1) \times \cdots \times D(U_m) \to D(W)
\]

\((V_1 \subseteq U_1, \ldots, V_m \subseteq U_m) \mapsto V_1 \cup \ldots \cup V_m \).

Consequently, we are reduced to proving that the \( \alpha \) induces an equivalence

\[
\lim_{\to} (\alpha \circ \psi_W) \to \lim_{\to} \psi_W.
\]

It will suffice to show that \( \alpha \) is left cofinal. This follows by applying Proposition T.4.1.1.3 to the commutative diagram

\[
\begin{array}{ccc}
N(\text{Disj}(U_1) \times \ldots \times \text{Disj}(U_n)) & \longrightarrow & D(U_1) \times \ldots \times D(U_m) \\
\downarrow & & \downarrow \alpha \\
N(\text{Disj}(W)) & \longrightarrow & D(W);
\end{array}
\]

note that the horizontal maps are left cofinal by Proposition 5.5.2.13, and the map \( \beta \) is an isomorphism of simplicial sets. \( \square \)
5.5. TOPOLOGICAL CHIRAL HOMOLOGY

To formulate assertion (2) more precisely, suppose we are given a pair of algebras $A, B \in \text{Alg}_{\mathbb{A}_d}(\mathcal{C})$. Let $f(A), f(B) \in \text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C})$ be given by operadic left Kan extension. Then $(f(A) \otimes f(B))|N(\text{Disk}(M))$ is an extension of $(A \otimes B)|N(\text{Disk}(M))$, so we have a canonical map $f(A \otimes B) \to f(A) \otimes f(B)$. We then have the following:

**Theorem 5.5.3.2.** Let $M$ be a manifold and $\mathcal{C} \otimes$ a sifted-complete symmetric monoidal $\infty$-category. Then for every pair of locally constant algebras $A, B \in \text{Alg}_{\mathbb{A}_d}(\mathcal{C})$, the canonical map $\theta : \int_M (A \otimes B) \to \int_M A \otimes \int_M B$ is an equivalence in $\mathcal{C}$.

We will deduce Theorem 5.5.3.2 from a more general result for covering spaces.

**Construction 5.5.3.3.** Let $M$ be a $k$-manifold and let $\pi : \tilde{M} \to M$ be a covering map with finite fibers, so that we have $\infty$-operads $p : \mathbb{E}_M^\otimes \to N(\text{Fin}_*)$ and $\tilde{p} : \mathbb{E}_{\tilde{M}}^\otimes \to N(\tilde{\text{Fin}}_*)$. For every finite set $S$ equipped with an embedding $j : \mathbb{R}^k \times S \hookrightarrow M$, the inverse image $\mathbb{R}^k \times S \times_M \tilde{M}$ has the form $\mathbb{R}^k \times \tilde{S}$, for some finite covering $\tilde{S}$ of $S$ (since the space $\mathbb{R}^k$ is simply connected). Moreover, there is an evident map $\tilde{j} : \mathbb{R}^k \times \tilde{S} \to \tilde{M}$. The construction $((\tilde{S}, j) \mapsto (\tilde{S}, \tilde{j}))$ determines a functor $U : \mathbb{E}_{\tilde{M}}^\otimes \to \mathbb{E}_M^\otimes$. The evident projections $\tilde{S} \to S$ determine a natural transformation $\alpha : \tilde{p} \circ U \to p$, which we can view as a map $\mathbb{E}_M^\otimes \times \Delta^1 \to N(\tilde{\text{Fin}}_*)$.

Let $q : \mathcal{C}^\otimes \to N(\tilde{\text{Fin}}_*)$ be a symmetric monoidal $\infty$-category. Composition with $U$ determines a functor.

$$\text{Fun}_N(\tilde{\text{Fin}}_*)(\mathbb{E}_{\tilde{M}}^\otimes, \mathcal{C}^\otimes) \xleftarrow{\alpha^!} \text{Fun}_N(\text{Fin}_*)(\mathbb{E}_M^\otimes, \mathcal{C}^\otimes)$$

Since $q$ is a coCartesian transformation, the natural transformation $\alpha$ determines a functor

$$\alpha^! : \text{Fun}_N(\text{Fin}_*)(\mathbb{E}_M^\otimes \times \{0\}, \mathcal{C}^\otimes) \to \text{Fun}_N(\tilde{\text{Fin}}_*)(\mathbb{E}_{\tilde{M}}^\otimes \times \{1\}, \mathcal{C}^\otimes).$$

Composing these functors and restricting to $\text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C}) \subseteq \text{Fun}_N(\text{Fin}_*)(\mathbb{E}_M^\otimes, \mathcal{C}^\otimes)$, we obtain a functor

$$\pi_* : \text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C}) \to \text{Alg}_{\mathbb{R}(\text{Disk}(\tilde{M}))}(\mathcal{C}).$$

**Remark 5.5.3.4.** Let $\pi : \tilde{M} \to M$ and $\mathcal{C}^\otimes$ be as in Construction 5.5.3.3. We can informally think of an object $A \in \text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C})$ as a family of $\mathbb{E}_k$-algebras $A_y \in \text{Alg}_{\mathbb{E}_k}(\mathcal{C})$, indexed by the points of $M$. In terms of this description, we can identify $\pi_* A \in \text{Alg}_{\mathbb{R}(\text{Disk}(\tilde{M}))}(\mathcal{C})$ with the family given by

$$(\pi_* A)_x = \bigotimes_{\pi(y) = x} A_y.$$

**Example 5.5.3.5.** Let $M$ be a manifold, let $S$ be a finite set, and let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category. Let $\pi : M \times S \to M$ denote the projection map, and let $A \in \text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C})$. Then $\pi_* A \simeq \bigotimes_{s \in S} A_s$, where $\{A_s\}_{s \in S}$ denotes the image of $A$ under the equivalence

$$\text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C}) \simeq \prod_{s \in S} \text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C})$$

of Example 5.4.5.4.

Let $\pi : \tilde{M} \to M$ be as in Construction 5.5.3.3. The construction $U \mapsto \pi^{-1} U$ determines a functors $\text{D}(M) \to \text{D}(\tilde{M})$ and $\text{Disj}(M) \to \text{Disj}(\tilde{M})$. For any algebra object $A \in \text{Alg}_{\mathbb{R}(\text{Disk}(M))}(\mathcal{C})$, the composite functors

$$\text{Disj}(M) \xrightarrow{\pi^{-1}} \text{Disj}(\tilde{M}) \xrightarrow{\pi^{-1}_*} \text{Disj}(M) \xrightarrow{\text{Disj}(M)} (\mathbb{E}_M^\otimes)^{\text{act}} \xrightarrow{\pi_* A} (\mathcal{C}^\otimes)^{\text{act}} \xrightarrow{\theta} \mathcal{C}$$

are homotopic to one another. We therefore obtain a canonical map $\int_M (\pi_* A) \to \int_M A$ (provided that both sides are defined).
Theorem 5.5.3.6. Let $\pi : \tilde{M} \to M$ be a covering map between manifolds which has finite fibers, and let $\mathcal{C}^\otimes$ be a sifted-complete symmetric monoidal $\infty$-category. For any algebra object $A \in \Alg_{\mathbb{E}_M}(\mathcal{C})$, the canonical map
\[ \int_M (\pi_* A) \to \int_{\tilde{M}} A \]
is an equivalence in $\mathcal{C}$.

Proof. Proposition 5.5.2.13 allows us to identify $\int_M (\pi_* A)$ with the colimit of a diagram $\phi : D(M) \to (\mathcal{C}^\otimes_M)^{\text{act}} \Delta^A \otimes (\mathcal{C}^\otimes)^{\text{act}} \to \mathcal{C}$ and $\int_{\tilde{M}} A$ with the colimit of a diagram $\psi : D(\tilde{M}) \to (\mathcal{C}^\otimes_{\tilde{M}})^{\text{act}} \Delta^A \otimes (\mathcal{C}^\otimes)^{\text{act}} \to \mathcal{C}$. The desired result now follows from the observation that $\pi^{-1} : D(M) \to D(\tilde{M})$ is left cofinal (Proposition 5.5.2.16).

Proof of Theorem 5.5.3.2. Let $A, B \in \Alg_{\mathbb{E}_M}(\mathcal{C})$. We may assume without loss of generality that $A$ and $B$ are given by the restriction of an algebra $C \in \Alg_{\mathbb{E}_M \otimes M}(\mathcal{C})$ (Example 5.4.5.4). We have a commutative diagram
\[ \int_M (A \otimes B) \xrightarrow{\theta} (\int_M A) \otimes (\int_M B) \xrightarrow{\theta''} \int_{M \otimes M} C. \]
The map $\theta'$ is an equivalence by Theorem 5.5.3.1, and the map $\theta''$ is an equivalence by Theorem 5.5.3.6 (see Example 5.5.3.5). It follows that $\theta$ is an equivalence, as desired. \qed

The proof of assertion (3) is based on the following simple observation:

Lemma 5.5.3.7. Let $M$ be a manifold and $\mathcal{E}$ an $\infty$-category which admits small colimits. Regard $\mathcal{E}$ as endowed with the coCartesian symmetric monoidal structure (see §2.4.3). Then, for every object $A \in \Alg_{\mathbb{E}_M}(\mathcal{E})$, the functor $\int M$ exhibits the topological chiral homology $\int_M A$ as the colimit of the diagram $A|N(\text{Disk}(M)) : N(\text{Disk}(M)) \to \mathcal{E}$.

Proof. Let $\chi : N(\text{Disj}(M)) \to \mathcal{E}$ be the functor given informally by the formula $\chi(U_1 \cup \cdots \cup U_n) = A(U_1 \amalg \cdots \amalg A(U_n))$, where the $U_i$ are disjoint open disks in $M$. We observe that $\chi$ is a left Kan extension of $\chi|N(\text{Disk}(M))$, so that $\int_M A \simeq \text{colim} \chi \simeq \text{colim}(\chi|N(\text{Disk}(M)))$ (see Lemma T.4.3.2.7). \qed

Theorem 5.5.3.8. Let $M$ be a manifold and $\mathcal{E}^\otimes$ a sifted-complete symmetric monoidal $\infty$-category. Regard the Kan complex $B_M$ as the underlying $\infty$-category of the $\infty$-operad $B^H_M$, and let $A \in \Alg_{B_M}(\mathcal{E})$ so that $\int_M A$ is well-defined (see Remark 5.5.2.9). Composing $A$ with the diagonal map $B_M \times N(\text{Fin}_*) \to B^H_M$, we obtain a functor $\psi : B_M \to \Alg(\mathcal{E})$. Let $A' = \text{colim}(\psi) \in \Alg(\mathcal{E})$. Then there is a canonical equivalence $\int_M A \simeq A'((1))$ in the $\infty$-category $\mathcal{E}$.

Remark 5.5.3.9. Let $A$ be as in the statement of Theorem 5.5.3.8. It follows from Theorem 2.4.3.18 that $A$ is determined by the functor $\psi$, up to canonical equivalence. In other words, we may identify $A \in \Alg_{B_M}(\mathcal{E})$ with a family of commutative algebra objects of $\mathcal{E}$ parametrized by the Kan complex $B_M$ (which is homotopy equivalent to $\text{Sing}(M)$, by virtue of Remark 5.4.5.2). Theorem 5.5.3.8 asserts that in this case, the colimit of this family of commutative algebras is computed by the formalism of topological chiral homology.

Proof of Theorem 5.5.3.8. Let $\phi : D(\text{Disk}(M))^\otimes \times \text{Fin}_* \to D(\text{Disk}(M))^\otimes$ be the functor given by the construction
\[ ((U_1, \ldots, U_m), (n)) \mapsto (U'_1, \ldots, U'_m), \]
where $U'_{m+i} = U_i$. Composing $\phi$ with the map $N(\text{Disk}(M))^\otimes \to B^H_M \xrightarrow{\Delta} \mathcal{E}^\otimes$, we obtain a locally constant algebra object $\tilde{A} \in \Alg_{N(\text{Disk}(M))}(\Alg(\mathcal{E}))$, where $\Alg(\mathcal{E})$ is endowed with the symmetric monoidal
structure given by pointwise tensor product (see Example 3.2.4.4). Since the symmetric monoidal structure on CAlg(ℰ) is coCartesian (Proposition 3.2.4.7), the colimit $\lim\limits_{\to} ψ$ can be identified with the topological chiral homology $\int_{S^1} A \in CAlg(ℰ)$. Let θ : CAlg(ℰ)$\otimes$ → ℰ denote the forgetful functor. We wish to prove the existence of a canonical equivalence $\theta(\int M A) ≃ \int M θ(A)$. In view of Proposition 5.5.2.17, it suffices to observe that θ is a symmetric monoidal functor and that the underlying functor CAlg(ℰ) → ℰ preserves sifted colimits (Proposition 5.2.3.1).

If M is an arbitrary k-manifold, we can view an $E_M$-algebra object of a symmetric monoidal ∞-category C as a family of $E_k$-algebras $\{A_x\}_{x \in M}$ parametrized by the points of M. In general, this family is “twisted” by the tangent bundle of M. In the special case where $M = S^1$, the tangent bundle $T_M$ is trivial, so we can think of an $E_M$-algebra as a family of associative algebras parametrized by the circle: that is, as an associative algebra A equipped with an automorphism σ (given by monodromy around the circle). Our final goal in this section is to show that in this case, the topological chiral homology $\int_{S^1} A$ coincides with the Hochschild homology of the A-bimodule corresponding to σ.

Fix an object of $D(S^1)$ corresponding to a single disk $ψ : R \hookrightarrow S^1$. An object of $D(S^1)_{ψ/}$ is given by a diagram

$$
\begin{array}{ccc}
R & \xrightarrow{j} & U \\
\downarrow{ψ} & & \downarrow{ψ'} \\
S^1 & \xrightarrow{\psi} & \psi'
\end{array}
$$

which commutes up to isotopy, where U is a finite union of disks. The set of components $π_0(S^1 - ψ'(U))$ is finite (equal to the number of components of U). Fix an orientation of the circle. We define a linear ordering ≤ on $π_0(S^1 - ψ'(U))$ as follows: if $x, y ∈ S^1$ belong to different components of $S^1 - ψ'(U)$, then we write $x < y$ if the three points $(x, y, ψ'(j(0)))$ are arranged in a clockwise order around the circle, and $y < x$ otherwise. This construction determines a functor from $D(S^1)_{ψ/}$ to (the nerve of) the category of nonempty finite linearly ordered sets, which is equivalent to $Δ^{op}$. A simple calculation yields the following:

Lemma 5.5.3.10. Let $M = S^1$, and let $ψ : R \hookrightarrow S^1$ be any open embedding. Then the above construction determines an equivalence of ∞-categories $θ : D(M)_{ψ/} → N(Δ^{op})$.

We can now formulate the relationship between Hochschild homology and topological chiral homology precisely as follows:

Theorem 5.5.3.11. Let $q : ℰ^{op} → N(∅_{|\cdot|})$ be a sifted-complete symmetric monoidal category. Let $A ∈ Alg_{Ga}(ℰ)$ be an algebra determining a diagram $χ : D(S^1) → ℰ$ whose colimit is $∫_{S^1} A$. Choose an open embedding $ψ : R \hookrightarrow S^1$. Then the restriction $χ|D(S^1)_{ψ/}$ is equivalent to a composition

$$
D(S^1)_{ψ/} \xrightarrow{θ} N(Δ^{op}) \xrightarrow{B_{∞}} ℰ,
$$

where θ is the equivalence of Lemma 5.5.3.10 and $B_{∞}$ is a simplicial object of ℰ. Moreover, there is a canonical equivalence $∫_{S^1} A ≃ |B_{∞}|$.

Lemma 5.5.3.12. Let ℰ be a nonempty ∞-category. Then ℰ is sifted if and only if, for each object $C ∈ ℰ$, the projection map $θ_C : ℰ_{C/} → ℰ$ is left cofinal.

Proof. According to Theorem T.4.1.3.1, the projection map $θ_C$ is left cofinal if and only if, for every object $D ∈ ℰ$, the ∞-category $ℰ_{C/} × ℰ_{D/}$ is weakly contractible. Using the evident isomorphism $ℰ_{C/} × ℰ_{D/} ≃ ℰ × ℰ_{(C,D)/}$, we see that this is equivalent to the left cofinality of the diagonal map $ℰ → ℰ × ℰ$ (Theorem T.4.1.3.1).

Proof of Theorem 5.5.3.11. The first assertion follows from Lemma 5.5.3.10. The second follows from the observation that $D(S^1)_{ψ/} → D(S^1)$ is a left cofinal map, by virtue of Lemma 5.5.3.12 and Proposition 5.5.2.15.
Remark 5.5.3.13. In the situation of Theorem 5.5.3.11, let us view $A$ as an associative algebra object of $\mathcal{C}$ equipped with an automorphism $\sigma$. We can describe the simplicial object $B_{\bullet}$ informally as follows. For each $n \geq 0$, the object $B_n \in \mathcal{C}$ can be identified with the tensor power $A^{\otimes(n+1)}$. For $0 \leq i < n$, the $i$th face map from $B_n$ to $B_{n-1}$ is given by the composition

$$B_n \simeq A^{\otimes i} \otimes (A \otimes A) \otimes A^{\otimes(n-1-i)} \rightarrow A^{\otimes i} \otimes A \otimes A^{\otimes(n-1-i)} \simeq B_{n-1},$$

where the middle map involves the multiplication on $A$. The $n$th face map is given instead by the composition

$$B_n \simeq (A \otimes A^{\otimes(n-1)}) \otimes A \simeq A \otimes (A \otimes A^{\otimes n-1}) \simeq (A \otimes A) \otimes A^{\otimes n-1} \rightarrow A \otimes A^{\otimes n-1} \simeq B_{n-1}.$$

Example 5.5.3.14. Let $\mathcal{E}$ denote the homotopy category of the $\infty$-operad $\mathcal{B}Top(1)^{\otimes}$, so that $N(\mathcal{E})$ is the $\infty$-operad describing associative algebras with involution (see Example 5.4.2.5). Then $N(\mathcal{E})$ contains a subcategory equivalent to the associative $\infty$-operad $Ass^{\otimes}$. Since the circle $S^1$ is orientable, the canonical map $E_{S^1} \rightarrow \mathcal{B}Top(1)^{\otimes} \rightarrow N(\mathcal{E})$ factors through this subcategory. We obtain by composition a functor $\text{Alg}(\mathcal{E}) \rightarrow \text{Alg}_{S^1}(\mathcal{E})$ for any symmetric monoidal $\infty$-category $\mathcal{E}$. If $\mathcal{E}$ admits sifted colimits and the tensor product on $\mathcal{E}$ preserves sifted colimits, we can then define the topological chiral homology $\int_{S^1} A$. It follows from Theorem 5.5.3.11 that this topological chiral homology can be computed in very simple terms: namely, it is given by the geometric realization of a simplicial object $B_{\bullet}$ of $\mathcal{E}$ consisting of iterated tensor powers of the algebra $A$. In fact, in this case, we can say more: the simplicial object $B_{\bullet}$ can be canonically promoted to a cyclic object of $\mathcal{E}$. The geometric realization of this cyclic object provides the usual bar resolution for computing the Hochschild homology of $A$.

5.5.4 Factorizable Cosheaves and Ran Integration

Let $M$ be a manifold and let $A$ be an $E_M$-algebra object of a sifted-complete symmetric monoidal $\infty$-category $\mathcal{C}^{\otimes}$. We refer to the object $\int_M A \in \mathcal{C}$ introduced in Definition 5.5.2.6 as the topological chiral homology of $M$ with coefficients in $A$, which is intended to suggest that (like ordinary homology) it enjoys some form of codescent with respect to open coverings in $M$. However, the situation is more subtle: the functor $U \mapsto \int_M A$ is not generally a cosheaf on the manifold $M$ itself (except in the situation described in Lemma 5.5.3.7). However, it can be used to construct a cosheaf on the Ran space $\text{Ran}(M)$ introduced in §5.5.1. In other words, we can view topological chiral homology as given by the procedure of integration over the Ran space (Theorem 5.5.4.14).

We begin with a review of the theory of cosheaves.

Definition 5.5.4.1. Let $\mathcal{E}$ be an $\infty$-category, $X$ a topological space, and $\mathcal{U}(X)$ the partially ordered set of open subsets of $X$. We will say that a functor $\mathcal{F} : N(\mathcal{U}(X)) \rightarrow \mathcal{E}$ is a cosheaf on $X$ if, for every object $C \in \mathcal{E}$, the induced map

$$(\mathcal{F}_C) : N(\mathcal{U}(X))^{op} \rightarrow \mathcal{E}^{op} \xrightarrow{\epsilon_C} S$$

is a sheaf on $X$, where $\epsilon_C : \mathcal{E}^{op} \rightarrow S$ denotes the functor represented by $\mathcal{E}$. We will say that a cosheaf $\mathcal{F} : N(\mathcal{U}(X)) \rightarrow \mathcal{E}$ is hypercomplete if each of the sheaves $\mathcal{F}_C \in \text{Shv}(X)$ is hypercomplete. If $X$ is the Ran space of a manifold $M$, we will say that $\mathcal{F}$ is constructible if each of the sheaves $\mathcal{F}_C$ is constructible in the sense of Definition 5.5.1.11.

Remark 5.5.4.2. Let $X$ be a topological space. It follows from Proposition 5.5.1.15 that a functor $\mathcal{F} : N(\mathcal{U}(X)) \rightarrow \mathcal{E}$ is a hypercomplete cosheaf on $X$ if and only if, for every open set $U \subseteq X$ and every functor $f : \mathcal{J} \rightarrow \mathcal{U}(U)$ with the property that $\mathcal{J}_x = \{J \in \mathcal{J} : x \in f(J)\}$ has weakly contractible nerve for each $x \in U$, the functor $\mathcal{F}$ exhibits $\mathcal{F}(U)$ as a colimit of the diagram $\{\mathcal{F}(f(J))\}_{J \in \mathcal{J}}$.

In particular, if $g : \mathcal{E} \rightarrow \mathcal{D}$ is a functor which preserves small colimits, then composition with $g$ carries hypercomplete cosheaves to hypercomplete cosheaves. Similarly, if $\mathcal{E} = \mathcal{P}(\mathcal{E})$ for some small $\infty$-category $\mathcal{E}$, a functor $\mathcal{F} : N(\mathcal{U}(X)) \rightarrow \mathcal{E}$ is a hypercomplete cosheaf if and only if, for every $E \in \mathcal{E}$, the functor $U \mapsto \mathcal{F}(U)(E)$ determines a cosheaf of spaces $N(\mathcal{U}(X)) \rightarrow S$. 
Our first goal in this section is to show that, if $M$ is a manifold, then we can identify $E_M$-algebras with a suitable class of cosheaves on the Ran space $\text{Ran}(M)$. To describe this class more precisely, we need to introduce a bit of terminology.

**Definition 5.5.4.3.** Let $M$ be a manifold, and let $U$ be a subset of $\text{Ran}(M)$. The support $\text{Supp} U$ of $U$ is the union $\bigcup_{S \in U} S \subseteq M$. We will say that a pair of subsets $U, V \subseteq \text{Ran}(M)$ are independent if $\text{Supp} U \cap \text{Supp} V = \emptyset$.

**Definition 5.5.4.4.** If $U$ and $V$ are subsets in $\text{Ran}(M)$, we let $U \star V$ denote the set $\{ S \cup T : S \in U, T \in V \} \subseteq \text{Ran}(M)$.

**Remark 5.5.4.5.** If $U$ is an open subset of $\text{Ran}(X)$, then $\text{Supp} U$ is an open subset of $X$.

**Example 5.5.4.6.** If $\{ U_i \}_{1 \leq i \leq n}$ is a nonempty finite collection of disjoint open subsets of a manifold $M$, then the open set $\text{Ran}(\{ U_i \}) \subseteq \text{Ran}(M)$ defined in §5.5.1 can be identified with $\text{Ran}(U_1) \star \text{Ran}(U_2) \star \cdots \star \text{Ran}(U_n)$.

**Remark 5.5.4.7.** If $U$ and $V$ are open in $\text{Ran}(M)$, then $U \star V$ is also open in $\text{Ran}(M)$.

**Remark 5.5.4.8.** We will generally consider the set $U \star V$ only in the case where $U$ and $V$ are independent subsets of $\text{Ran}(M)$. In this case, the canonical map $U \times V \to U \star V$ given by the formula $(S, T) \mapsto S \cup T$ is a homeomorphism.

**Definition 5.5.4.9.** Let $M$ be a manifold. We define a category $\text{Fact}(M)^\otimes$ as follows:

1. The objects of $\text{Fact}(M)^\otimes$ are finite sequences $(U_1, \ldots, U_n)$ of open subsets $U_i \subseteq \text{Ran}(M)$.
2. A morphism from $(U_1, \ldots, U_m)$ to $(V_1, \ldots, V_n)$ in $\text{Fact}(M)$ is a surjective map $\alpha : \langle m \rangle \to \langle n \rangle$ in $\text{Fin}_*$ with the following property: for $1 \leq i \leq n$, the sets $\{ U_j \}_{\alpha(j) = i}$ are pairwise independent and $\star_{\alpha(j) = i} U_j \subseteq V_i$.

We let $\text{Fact}(M) \subseteq \text{Fact}(M)^\otimes$ denote the fiber product $\text{Fact}(M)^\otimes \times_{\text{Fin}_*} \{ 1 \}$, so that $\text{Fact}(M)$ is the category whose objects are open subsets of $\text{Ran}(M)$ and whose morphisms are inclusions of open sets.

The $\infty$-category $\text{N}(\text{Fact}(M)^\otimes)$ is an $\infty$-operad. Moreover, there is a canonical map of $\infty$-operads $\Psi : \text{N}(\text{Disk}(M))_{\text{nu}}^\otimes \to \text{N}(\text{Fact}(M)^\otimes)$, given on objects by the formula $(U_1, \ldots, U_n) \mapsto (\text{Ran}(U_1), \ldots, \text{Ran}(U_n))$.

We can now state our main result:

**Theorem 5.5.4.10.** Let $M$ be a manifold and let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{C}$ admits small colimits and that the tensor product on $\mathcal{C}$ preserves small colimits separately in each variable. Then the operation of operadic left Kan extension along the inclusion $\Psi : \text{N}(\text{Disk}(M))_{\text{nu}}^\otimes \to \text{N}(\text{Fact}(M)^\otimes)$ determines a fully faithful embedding $F : \text{Alg}^\text{nu}_{\text{Disk}(M)}(\mathcal{C}) \to \text{Alg}^\text{nu}_{\text{Fact}(M)}(\mathcal{C})$. Moreover, the essential image of the full subcategory $\text{Alg}^\text{nu}_{\text{Fact}(M)}(\mathcal{C})$ spanned by the locally constant objects of $\text{Alg}^\text{nu}_{\text{Disk}(M)}(\mathcal{C})$ is the full subcategory of $\text{Alg}_{\text{Fact}(M)}(\mathcal{C})$ spanned by those objects $A$ satisfying the following conditions:

1. The restriction of $A$ to $\text{N}(\text{Fact}(M))$ is a constructible cosheaf on $\text{Ran}(M)$, in the sense of Definition 5.5.4.1.
2. Let $U, V \subseteq \text{Ran}(M)$ be independent open sets. Then the induced map $A(U) \otimes A(V) \to A(U \star V)$ is an equivalence in $\mathcal{C}$.

**Remark 5.5.4.11.** In view of Proposition 5.4.5.15, we can formulate Theorem 5.5.4.10 more informally as follows: giving a nonunital $E_M$-algebra object of the $\infty$-category $\mathcal{C}$ is equivalent to giving a constructible $\mathcal{C}$-valued cosheaf $\mathcal{F}$ on the Ran space $\text{Ran}(M)$, with the additional feature that $\mathcal{F}(U \star V) \simeq \mathcal{F}(U) \otimes \mathcal{F}(V)$ when $U$ and $V$ are independent subsets of $\text{Ran}(M)$. Following Beilinson and Drinfeld, we will refer a cosheaf with this property as a *factorizable* cosheaf on $\text{Ran}(M)$.
If $M$ is a manifold, let $\text{Ran}^+(M)$ denote the collection of all finite subsets of $M$, so that $\text{Ran}^+(M) = \text{Ran}(M) \cup \{\emptyset\}$. We regard $\text{Ran}^+(M)$ as a topological space, taking as a basis those subsets of the form $\text{Ran}^+(U)$ where $U$ is an open subset of $M$. Note that this topology is usually not Hausdorff: for example, $\emptyset \in \text{Ran}^+(M)$ belongs to every nonempty open subset of $M$. It is possible to obtain a unital analogue of the easy part of Theorem 5.5.4.10: the formation of peripadric left Kan extensions embeds the $\infty$-category $\text{Alg}_{\text{N}(\text{Disk}(M))}(\mathcal{C})$ as a full subcategory of an $\infty$-category of factorizable cosheaves on $\text{Ran}^+(M)$. However, we do not know if there is a simple description of the essential image of the locally constant $\text{N}(\text{Disk}(M))$-algebras.

The proof of Theorem 5.5.4.10 rests on the following basic calculation:

**Lemma 5.5.4.13.** Let $M$ be a $k$-manifold, let $D \in (\mathbb{E}_M)^{\text{nu}}$ be an object (corresponding to a nonempty finite collection of open embeddings $\{\psi_i : \mathbb{R}^k \to M\}_{1 \leq i \leq m}$), let $\chi : N(\text{Disj}(M)) \to S$ be a functor classified by the left fibration $N(\text{Disj}(M)) \times_{\mathbb{E}_M} (\mathbb{E}_M)^{\text{nu}}$ (here $\text{Disj}(M)$ is defined as in Proposition 5.5.2.13), and let $\chi' : N(\text{Fact}(M)) \to S$ be a left Kan extension of $\chi$. Then $\chi'$ is a hypercomplete $S$-valued cosheaf.

**Proof.** Recall that a natural transformation of functors $\alpha : F \to G$ from an $\infty$-category $\mathcal{C}$ to $\mathcal{D}$ is said to be Cartesian if, for every morphism $C \to D$ in $\mathcal{C}$, the induced diagram

$$
\begin{array}{ccc}
F(C) & \longrightarrow & F(D) \\
\downarrow & & \downarrow \\
G(C) & \longrightarrow & G(D)
\end{array}
$$

is a pullback square in $\mathcal{D}$. Let $D'$ be the image of $D$ in $B\text{Top}(k)^{\text{op}}$, and let $\chi' : N(\text{Disj}(M)) \to S$ be a functor classified by the left fibration $N(\text{Disj}(M)) \times_{B\text{Top}(k)^{\text{op}}} (B\text{Top}(k)^{\text{op}})^{\text{nu}}$. There is an evident natural transformation of functors $\beta : \chi \to \chi'$, which induces a natural transformation $\beta' : \chi' \to \chi''$, where $\chi'' : N(\text{Fact}(M)) \to S$ is a functor given by the formula $V \mapsto \text{Sing} \text{Conf}'(S, V)$, where $\text{Sing} \text{Conf}'(S, V)$ is the summand consisting of injective maps $i : S \to V$ which are surjective on connected components. Let $\chi'' : N(\text{Disj}(M)) \to S$ be the functor given by the formula $V \mapsto \text{Sing} \text{Conf}'(S, V)$, where $\text{Sing} \text{Conf}'(S, V)$ is the summand consisting of injective maps $i : S \to V$ which are surjective on connected components. We have an evident natural transformation of functors $\gamma : \chi' \to \chi''$. Using Remark 4.1.10, we deduce that $\gamma$ is Cartesian, so that $\alpha = \gamma \circ \beta$ is a Cartesian natural transformation from $\chi$ to $\chi''$.

Let $\phi : \text{Conf}(S, M) \to \text{Ran}(M)$ be the continuous map which assigns to each configuration $i : S \to M$ its image $i(S) \subseteq M$ (so that $\phi$ exhibits $\text{Conf}(S, M)$ as a finite covering space of $\text{Ran}^{nu}(M) \subseteq \text{Ran}(M)$). Let $\chi''' : N(\text{Fact}(M)) \to S$ be the functor given by the formula $U \mapsto \text{Sing} \phi^{-1}(U)$. We observe that $\chi'''$ is canonically equivalent to $\chi''$. We claim that $\chi'''$ is a left Kan extension of $\chi''$. To prove this, it suffices to show that for every open subset $U \subseteq \text{Ran}(M)$, the map $\chi'''$ exhibits $\text{Sing} \phi^{-1}(U)$ as a colimit of the diagram $\{\chi''(V)\}_{V \in \beta}$, where $\beta \subseteq \text{Disj}(M)$ is the full subcategory spanned by those unions of disks $V = U_1 \cup \ldots \cup U_n$ such that $\text{Ran}(\{U_i\}) \subseteq U$. For each $x \in \phi^{-1}(U)$, let $\beta_x$ denote the full subcategory of $\beta$ spanned by those open sets $V$ such that the map $x : S \to M$ factors through a map $S \to V$ which is surjective on connected components.

In view of Theorem A.3.1, it will suffice to show that $\beta_x$ has weakly contractible nerve. In fact, we claim that $\beta_x^{\text{op}}$ is filtered: this follows from the observation that every open neighborhood of $x(S)$ contains an open set of the form $U_1 \cup \ldots \cup U_n$, where the $U_i$ are a collection of small disjoint disks containing the elements of $x(S)$.

The map $\alpha$ induces a natural transformation $\alpha' : \chi' \to \chi''$. Using Theorem T.6.1.3.9, we deduce that $\alpha'$ is also a Cartesian natural transformation. We wish to show that $\alpha'$ satisfies the criterion of Remark 5.5.4.2. In other words, we wish to show that if $U \subseteq \text{Ran}(M)$ is an open subset and $f : J \to \text{Fact}(M)$ is a diagram such that each $f(I) \subseteq U$ and the full subcategory $\beta_x = \{I \in J : x \in f(I)\}$ has weakly contractible nerve for each $x \in U$, then $\chi$ exhibits $\chi'(U)$ as a colimit of the diagram $\{\chi'(f(I))\}_{I \in \beta}$. By virtue of Theorem T.6.1.3.9, it will suffice to show that $\chi'$ exhibits $\chi''(U)$ as a colimit of the diagram $\{\chi''(f(I))\}_{I \in \beta}$. This is an immediate consequence of Theorem A.3.1.

\qed
Proof of Theorem 5.5.4.10. The existence of the functor $F$ follows from Corollary 3.1.3.5. Let $A_0$ be a nonunital $N(Disk(M))^\otimes$-algebra object of $\mathcal{C}$. Using Corollary 3.1.3.5, Proposition 3.1.1.15, and Proposition 3.1.1.16, we see that $A = F(A_0)$ can be described as an algebra which assigns to each $U \subseteq \text{Ran}(M)$ a colimit of the diagram

$$\chi_U : N(Disk(M))^\otimes \times_{N(Fact(M)^\otimes)} N(Fact(M)^\otimes)_{/U} \to \mathcal{C}.$$  

The domain of this functor can be identified with the nerve of the category $\mathcal{C}_U$ whose objects are finite collections of disjoint disks $V_1, \ldots, V_n \subseteq M$ such that $\text{Ran}({\{V_i\}}) \subseteq U$. In particular, if $U = \text{Ran}(U')$ for some open disk $U' \subseteq M$, then the one-element sequence $(U')$ is a final object of $\mathcal{C}_U$. It follows that the canonical map $A_0 \to A|N(Disk(M))^\otimes$ is an equivalence, so that the functor $F$ is fully faithful.

We next show that if $A = F(A_0)$ for some $A_0 \in \text{Alg}_{N(Disk(M))}(\mathcal{C})$, then $A$ satisfies conditions (1) and (2). To prove that $A$ satisfies (2), we observe that if $U, V \subseteq \text{Ran}(M)$ are independent then we have a canonical equivalence $\mathcal{C}_U \times \mathcal{C}_V \simeq \mathcal{C}_U \times \mathcal{C}_V$. Under this equivalence, the functor $\chi_{U \times V}$ is given by the tensor product of the functors $\chi_U$ and $\chi_V$. The map $A(U) \otimes A(V) \to A(U \times V)$ is a homotopy inverse to the equivalence

$$\lim_{N(\mathcal{C}_U)} \chi_{U \times V} \simeq \lim_{N(\mathcal{C}_U) \times N(\mathcal{C}_V)} \chi_U \otimes \chi_V \to \left( \lim_{N(\mathcal{C}_U)} \chi_U \right) \otimes \left( \lim_{N(\mathcal{C}_V)} \chi_V \right)$$

provided by our assumption that the tensor product on $\mathcal{C}$ preserves small colimits separately in each variable.

We next show that $A|N(Fact(M))$ is a hypercomplete cosheaf on $\text{Ran}(M)$. By virtue of Proposition 5.4.5.15, we can assume that $A_0$ factors as a composition

$$\text{Disk}(M)^\otimes \to (E_M^\otimes)^\mu \to \mathcal{C}^\otimes.$$ 

Let $\mathcal{D}$ be the subcategory of $(E_M^\otimes)^\mu$ spanned by the active morphisms. As explained in §2.2.4, the $\infty$-category $\mathcal{D}$ admits a symmetric monoidal structure and we may assume that $A_0'$ factors as a composition

$$(E_M^\otimes)^\mu \to \mathcal{D}^\otimes \xrightarrow{T} \mathcal{C}^\otimes,$$

where $A_0''$ is a symmetric monoidal functor. Corollary 4.8.1.12 implies that the $\mathcal{P}(\mathcal{D})$ inherits a symmetric monoidal structure, and that $A_0''$ factors (up to homotopy) as a composition

$$\mathcal{D}^\otimes \to \mathcal{P}(\mathcal{D})^\otimes \xrightarrow{T} \mathcal{C}^\otimes$$

where $T$ is a symmetric monoidal functor such that the underlying functor $T_{(1)} : \mathcal{P}(\mathcal{D}) \to \mathcal{C}$ preserves small colimits. Let $B_0$ denote the composite map

$$\text{Disk}(M)^\otimes \to (E_M^\otimes)^\mu \to \mathcal{D}^\otimes \to \mathcal{P}(\mathcal{D})^\otimes,$$

and let $B \in \text{Alg}_{\text{Fact}(M)}(\mathcal{P}(\mathcal{D}))$ be an operadic left $B_0$ to $B_0$ and $A \simeq T \circ B_0$. Since $T_{(1)}$ preserves small colimits, it will suffice to show that $B|\text{Fact}(M)$ is a hypercomplete $\mathcal{P}(\mathcal{D})$-valued cosheaf on $\text{Ran}(M)$ (Remark 5.5.4.2). Fix an object $D \in \mathcal{D}$, and let $e_D : \mathcal{P}(\mathcal{D}) \to S$ be the functor given by evaluation on $D$. In view of Remark 5.5.4.2, it will suffice to show that $e_D \circ (B|\text{Fact}(M))$ is a hypercomplete $S$-valued cosheaf on $\text{Ran}(M)$. The desired result is now a translation of Lemma 5.5.4.13.

To complete the proof that $A$ satisfies (1), it suffices to show that for each $C \in \mathcal{C}$, the functor $U \mapsto \text{Map}_{\mathcal{C}}(A(U), C)$ satisfies condition $(\ast)$ of Proposition 5.5.1.14. Let $U_1, \ldots, U_n \subseteq M$ be disjoint disks containing smaller disks $V_1, \ldots, V_n \subseteq M$; it will suffice to show that the corestriction map $A(\text{Ran}({\{V_i\}})) \to A(\text{Ran}({\{U_i\}}))$ is an equivalence in $\mathcal{C}$. Since $A$ satisfies (2), we can reduce to the case where $n = 1$. In this case, we have a commutative diagram

$$\begin{array}{ccc}
A_0(V_1) & \xrightarrow{\beta} & A_0(U_1) \\
\downarrow & & \downarrow \\
A(\text{Ran}(V_1)) & \xrightarrow{\beta'} & A(\text{Ran}(U_1)).
\end{array}$$
The vertical maps are equivalences (since \( F \) is fully faithful), and the map \( \beta \) is an equivalence because \( A_0 \) is locally constant.

Now suppose that \( A \in \text{Alg}_{N(Disk(M))}(\mathcal{C}) \) satisfies conditions (1) and (2); we wish to prove that \( A \) lies in the essential image of \( F|_{\text{Alg}_{N(Disk(M))}^{\text{loc,nu}}}(\mathcal{C}) \). Let \( A_0 = A|_{N(Disk(M))}^{\otimes} \). Since \( A \) satisfies (1), Proposition 5.5.1.14 guarantees that \( A_0 \) is locally constant; it will therefore suffice to show that the canonical map \( F(A_0) \to A \) is an equivalence in the \( \infty \)-category \( \text{Alg}_{N(Disk(M))}(\mathcal{C}) \). It will suffice to show that for every open set \( U \subseteq \text{Ran}(M) \) and every object \( C \in \mathcal{C} \), the induced map \( \alpha_U : \text{Map}_C(A(U), C) \to \text{Map}_C(F(A_0)(U), C) \) is a homotopy equivalence of spaces. Since \( A \) and \( F(A_0) \) both satisfy condition (1), the collection of open sets \( U \) such that \( \alpha_U \) is a homotopy equivalence is stable under unions of hypercovers. Consequently, Remark 5.5.1.4 allows us to assume that \( U = \text{Ran}(V_1) \star \cdots \star \text{Ran}(V_n) \) for some collection of disjoint open disks \( V_1, \ldots, V_n \subseteq M \). We claim that \( \beta : F(A_0)(U) \to A(U) \) is an equivalence. Since \( A \) and \( F(A_0) \) both satisfy (2), it suffices to prove this result after replacing \( U \) by \( \text{Ran}(V_i) \) for \( 1 \leq i \leq n \). We may therefore assume that \( U = \text{Ran}(V) \) for some open disk \( V \subseteq M \). In this case, we have a commutative diagram

\[
\begin{array}{ccc}
A_0(V) & \xrightarrow{\beta'} & \beta'' \xrightarrow{\beta''} A(U).
\end{array}
\]

The map \( \beta' \) is an equivalence by the first part of the proof, and \( \beta'' \) is an equivalence by construction. The two-out-of-three property shows that \( \beta \) is also an equivalence, as desired.

The construction of topological chiral homology is quite closely related to the left Kan extension functor \( F \) studied in Theorem 5.5.4.10. Let \( M \) be a manifold, let \( \mathcal{A} \in \text{Alg}_{N(Disk(M))}(\mathcal{C}) \), and let \( A_0 = A|_{N(Disk(M))}^{\otimes} \). Evaluating \( \Psi(A_0) \) on the Ran space \( \text{Ran}(M) \), we obtain an object of \( \mathcal{C} \) which we will denote by \( \mathcal{J}^\text{nu}_M A \). Unwinding the definition, we see that \( \mathcal{J}^\text{nu}_M A \) can be identified with the colimit \( \lim_{\mathcal{J}^\text{nu}_M} \chi(V) \), where \( \chi : N(\text{Disj}(M)) \to \mathcal{C} \) is the functor given informally by the formula \( \chi(U_1 \cup \cdots \cup U_n) = A(U_1) \otimes \cdots \otimes A(U_n) \). The topological chiral homology \( \mathcal{J}^\text{nu}_M A \) is given by the colimit \( \lim_{\mathcal{J}^\text{nu}_M} \chi(V) \). The inclusion of \( \text{Disj}(M)^{\text{mu}} \) into \( \text{Disj}(M)^{\text{nu}} \) induces a map \( \mathcal{J}^\text{mu}_M A \to \mathcal{J}^\text{nu}_M A \). We now have the following result:

**Theorem 5.5.4.14.** Let \( M \) be a manifold and \( C^{\otimes} \) a symmetric monoidal \( \infty \)-category. Assume that \( C \) admits small colimits and that the tensor product on \( C \) preserves colimits separately in each variable, and let \( A \in \text{Alg}_{N(Disk(M))}(\mathcal{C}) \). Suppose that \( M \) is connected and that \( A \) is locally constant. Then the canonical map \( \mathcal{J}^\text{mu}_M A \to \mathcal{J}^\text{nu}_M A \) is an equivalence in \( C \).

**Proof.** The map \( A \) determines a diagram \( \psi : N(\text{Disj}(M)) \to \mathcal{C} \), given informally by the formula \( \psi(U_1 \cup \cdots \cup U_n) = A(U_1) \otimes \cdots \otimes A(U_n) \). We wish to prove that the canonical map \( \theta : \lim_{\mathcal{J}^\text{mu}_M} (\psi|N(\text{Disj}(M)^{\text{mu}})) \to \lim_{\mathcal{J}^\text{nu}_M} (\psi) \) is an equivalence. Since \( A \) is locally constant, we can use Theorem 5.4.5.9 to reduce to the case where \( A \) factors as a composition \( \text{Disk}(M)^{\otimes} \to \mathcal{E}_M A' \). In this case, \( \psi \) factors as a composition \( N(\text{Disj}(M)) \to D(M) \psi' \to \mathcal{C} \), so we have a commutative diagram

\[
\begin{array}{ccc}
\lim_{\mathcal{J}^\text{nu}_M} (\psi|N(\text{Disj}(M)^{\text{mu}})) & \xrightarrow{\theta} & \lim_{\mathcal{J}^\text{nu}_M} (\psi) \\
\theta' & \downarrow & \theta'' \\
\lim_{\mathcal{J}^\text{nu}_M} (\psi').
\end{array}
\]

Proposition 5.5.2.13 guarantees that \( \theta' \) and \( \theta'' \) are equivalences in \( C \), so that \( \theta \) is an equivalence by the two-out-of-three property.
5.5. TOPOLOGICAL CHIRAL HOMOLOGY

Theorem 5.5.4.14 can be regarded as making the functor $\Psi$ of Theorem 5.5.4.10 more explicit: if $A_0$ is a locally constant quasi-unital $N(Disk(M))^\otimes$-algebra and $M$ is connected, then the global sections of the associated factorizable cosheaf can be computed by the topological chiral homology construction of Definition 5.5.2.6. We can also read this theorem in the other direction. If $A$ is a locally constant $N(Disk(M))^\otimes$-algebra, the the functor $U \mapsto \int_A U$ does not determine a cosheaf $N(\mathfrak{t}(M)) \to \mathcal{C}$ in the sense of Definition 5.5.4.1. However, when $U$ is connected, the topological chiral homology $\int_A U$ can be computed as the global sections of a sheaf on the Ran space $\text{Ran}(U)$. This is a reflection of a more subtle sense in which the construction $U \mapsto \int_A U$ behaves “locally in $U$.” We close this section with a brief informal discussion.

Let $M$ be a manifold of dimension $k$, and let $N \subseteq M$ be a submanifold of dimension $k - d$ which has a trivial neighborhood of the form $N \times \mathbb{R}^d$. Let $A \in \text{Alg}_{N(\mathbb{R}^d)}(\mathcal{C})$ and let $\int(A)$ denote the associated $N(Disk(M))^\otimes$-algebra object of $\mathcal{C}$. Restricting $\int(A)$ to open subsets of $M$ of the form $N \times V$, where $V$ is a union of finitely many open disks in $\mathbb{R}^d$, we obtain another algebra $A_N \in \text{Alg}_{N(Disk(\mathbb{R}^d))}(\mathcal{C})$. This algebra is locally constant, and can therefore be identified with an $\mathbb{E}_d$-algebra object of $\mathcal{C}$ (Theorem 5.4.5.9). We will denote this algebra by $\int_N A$.

**Warning 5.5.4.15.** This notation is slightly abusive: the $\mathbb{E}_d$-algebra $\int_N A$ depends not only on the closed submanifold $N \subseteq M$ but also on a trivialization of a neighborhood of $N$.

Suppose now that $d = 1$, and that $N \subseteq M$ is a hypersurface which separates the connected manifold $M$ into two components. Let $M_+$ denote the union of one of these components with the neighborhood $N \times \mathbb{R}$ of $N$, and $M_-$ the union of the other component with $N \times \mathbb{R}$ of $N$. After choosing appropriate conventions regarding the orientation of $\mathbb{R}$, we can endow the topological chiral homology $\int_{M_+} A$ with the structure of a right module over $\int_N A$ (which we will identify with an associative algebra object of $\mathcal{C}$), and $\int_{M_-} A$ with the structure of a left module over $\int_N A$. There is a canonical map

$$ (\int_{M_+} A) \otimes_{\int_N A} (\int_{M_-} A) \to \int_N A, $$

which can be shown to be an equivalence. In other words, we can recover the topological chiral homology $\int_M A$ of the entire manifold $M$ if we understand the topological chiral homologies of $M_+$ and $M_-$, together with their interface along the hypersurface $N$.

Using more elaborate versions of this analysis, one can compute $\int_M A$ using any sufficiently nice decomposition of $M$ into manifolds with corners (for example, from a triangulation of $M$). This can be made precise using the formalism of extended topological quantum field theories (see [98] for a sketch).

**Example 5.5.4.16.** Let $M = \mathbb{R}^k$, so that the $\infty$-operad $\mathbb{E}_{\mathbb{R}^k}_M$ is equivalent to $\mathbb{E}_{\mathbb{R}^k}$. Let $N = S^{k-1}$ denote the unit sphere in $\mathbb{R}^k$. We choose a trivialization of the normal bundle to $N$ in $M$, which assigns to each point $x \in S^{k-1} \subseteq \mathbb{R}^k$ the “inward pointing” normal vector given by $-x$ itself. According to the above discussion, we can associate to any algebra object $A \in \text{Alg}_{\mathbb{E}_{\mathbb{R}^k}}(\mathcal{C})$ an $\mathbb{E}_1$-algebra object of $\mathcal{C}$, which we will denote by $B = \int_{S^{k-1}} A$. Using Example 5.1.0.7, we can identify $B$ with an associative algebra object of $\mathcal{C}$. One can show that this associative algebra has the following property: there is an equivalence of $\infty$-categories $\theta : \text{Mod}_{\mathbb{E}_{\mathbb{R}^k}}^B(\mathcal{C}) \simeq \text{LMod}_B(\mathcal{C})$ which fits into a commutative diagram of $\infty$-categories

$$ \text{Mod}_{\mathbb{E}_{\mathbb{R}^k}}^B(\mathcal{C}) \xrightarrow{\theta} \text{LMod}_B(\mathcal{C}) $$

which are right-tensored over $\mathcal{C}$ (in view of Theorem 4.8.5.5, the existence of such a diagram characterizes the object $B \in \text{Alg}(\mathcal{C})$ up to canonical equivalence). Under the equivalence $\theta$, the left $B$-module $B$ corresponds to the object $F(\mathbf{1}) \in \text{Mod}_{\mathbb{E}_{\mathbb{R}^k}}^B(\mathcal{C})$ appearing in the statement of Theorem 7.3.5.1.
5.5.5 Verdier Duality

Our goal in this section is to prove the following result:

**Theorem 5.5.5.1** (Verdier Duality). Let $\mathcal{C}$ be a stable $\infty$-category which admits small limits and colimits, and let $X$ be a locally compact Hausdorff space. There is a canonical equivalence of $\infty$-categories

$$D : \text{Shv}(X; \mathcal{C})^{\text{op}} \simeq \text{Shv}(X; \mathcal{C}^{\text{op}}).$$

**Remark 5.5.5.2.** Let $k$ be a field and let $\mathcal{A}$ denote the category of chain complexes of $k$-vector spaces. Then $\mathcal{A}$ has the structure of a simplicial category; we let $\mathcal{N}(\mathcal{A})$ denote the nerve of $\mathcal{A}$ (that is, the derived $\infty$-category of the abelian category of $k$-vector spaces; see Definition 1.3.2.7). Vector space duality induces a simplicial functor $\mathcal{A}^{\text{op}} \to \mathcal{A}$, which in turn gives rise to a functor $\mathcal{C}^{\text{op}} \to \mathcal{C}$. This functor preserves limits, and therefore induces a functor $\text{Shv}(X; \mathcal{C}^{\text{op}}) \to \text{Shv}(X; \mathcal{C})$ for any locally compact Hausdorff space $X$. Composing this map with the equivalence $D$ of Theorem 5.5.5.1, we obtain a functor $D' : \text{Shv}(X; \mathcal{C})^{\text{op}} \to \text{Shv}(X, \mathcal{C})$: that is, a contravariant functor from $\text{Shv}(X; \mathcal{C})$ to itself.

It is the functor $D'$ which is usually referred to as Verdier duality. Note that $D'$ is not an equivalence of $\infty$-categories: it is obtained by composing the equivalence $D$ with vector space duality, which fails to be an equivalence unless suitable finiteness restrictions are imposed. We refer the reader to [156] for further discussion.

The first step in the proof of Theorem 5.5.5.1 is to choose a convenient model for the $\infty$-category $\text{Shv}(X; \mathcal{C})$ of $\mathcal{C}$-valued sheaves on $X$. Let $\mathcal{K}(X)$ denote the collection of all compact subsets of $X$, regarded as a partially ordered set with respect to inclusion. Recall (Definition T.7.3.4.1) that a $\mathcal{K}$-sheaf on $X$ (with values in an $\infty$-category $\mathcal{C}$) is a functor $\mathcal{F} : N(\mathcal{K}(X))^{\text{op}} \to \mathcal{C}$ with the following properties:

(i) The object $\mathcal{F}(\emptyset) \in \mathcal{C}$ is final.

(ii) For every pair of compact sets $K, K' \subseteq X$, the diagram

$$\xymatrix{ \mathcal{F}(K \cup K') \ar[r] \ar[d] & \mathcal{F}(K) \ar[d] \\ \mathcal{F}(K') \ar[r] & \mathcal{F}(K \cap K') }$$

is a pullback square in $\mathcal{C}$.

(iii) For every compact set $K \subseteq X$, the canonical map $\lim_{K'} \mathcal{F}(K') \to \mathcal{F}(K)$ is an equivalence, where $K'$ ranges over all compact subsets of $X$ which contain a neighborhood of $K$.

We let $\text{Shv}_{\mathcal{K}}(X; \mathcal{C})$ denote the full subcategory of $\text{Fun}(N(\mathcal{K}(X))^{\text{op}}, \mathcal{C})$ spanned by the $\mathcal{K}$-sheaves. We now have the following:

**Lemma 5.5.5.3.** Let $X$ be a locally compact Hausdorff space and $\mathcal{C}$ a stable $\infty$-category which admits small limits and colimits. Then there is a canonical equivalence of $\infty$-categories $\text{Shv}(X; \mathcal{C}) \simeq \text{Shv}_{\mathcal{K}}(X; \mathcal{C})$.

**Proof.** Since $\mathcal{C}$ is stable, filtered colimits in $\mathcal{C}$ are left exact. The desired result is now a consequence of Theorem T.7.3.4.9 (note that Theorem T.7.3.4.9 is stated under the hypothesis that $\mathcal{C}$ is presentable, but this hypothesis is used only to guarantee the existence of small limits and colimits in $\mathcal{C}$).

Using Lemma 5.5.5.3, we can reformulate Theorem 5.5.5.1 as follows:

**Theorem 5.5.5.4.** Let $X$ be a locally compact Hausdorff space and let $\mathcal{C}$ be a stable $\infty$-category which admits small limits and colimits. Then there is a canonical equivalence of $\infty$-categories

$$\text{Shv}_{\mathcal{K}}(X; \mathcal{C})^{\text{op}} \simeq \text{Shv}_{\mathcal{K}}(X; \mathcal{C}^{\text{op}}).$$
We will prove Theorem 5.5.5.4 by introducing an $\infty$-category which is equivalent to both $\text{Shv}_X(X; \mathcal{C})^{\text{op}}$ and $\text{Shv}_X(X; \mathcal{C})^{\text{op}}$.

**Notation 5.5.5.5.** Fix a locally compact Hausdorff space $X$. We define a partially ordered set $M$ as follows:

1. The objects of $M$ are pairs $(i, S)$ where $0 \leq i \leq 2$ and $S$ is a subset of $X$ such that $S$ is compact if $i = 0$ and $X - S$ is compact if $i = 2$.
2. We have $(i, S) \leq (j, T)$ if either $i \leq j$ and $S \subseteq T$, or $i = 0$ and $j = 2$.

**Remark 5.5.5.6.** The projection $(i, S) \mapsto i$ determines a map of partially ordered sets $\phi : M \to [2]$. For $0 \leq i \leq 2$, we let $M_i$ denote the fiber $\phi^{-1}\{i\}$. We have canonical isomorphisms $M_0 \simeq \mathcal{K}(X)$ and $M_2 \simeq \mathcal{K}(X)^{\text{op}}$, while $M_1$ can be identified with the partially ordered set of all subsets of $X$.

The proof of Theorem 5.5.5.4 rests on the following:

**Proposition 5.5.5.7.** Let $X$ be a locally compact Hausdorff space, $\mathcal{C}$ a stable $\infty$-category which admits small limits and colimits, and let $M$ be the partially ordered set of Notation 5.5.5.5. Let $F : N(M) \to \mathcal{C}$ be a functor. The following conditions are equivalent:

1. The restriction $(F|N(M_0))^{\text{op}}$ determines a $\mathcal{K}$-sheaf $N(\mathcal{K}(X))^{\text{op}} \to \mathcal{C}^{\text{op}}$, the restriction $F|N(M_1)$ is zero, and $F$ is a left Kan extension of the restriction $F|N(M_0 \cup M_1)$.
2. The restriction $F|N(M_2)$ determines a $\mathcal{K}$-sheaf $N(\mathcal{K}(X))^{\text{op}} \to \mathcal{C}$, the restriction $F|N(M_1)$ is zero, and $F$ is a right Kan extension of $F|N(M_0 \cup M_2)$.

Assuming Proposition 5.5.5.7 for the moment, we can give the proof of Theorem 5.5.5.4.

**Proof of Theorem 5.5.5.4.** Let $\mathcal{E}(\mathcal{C})$ be the full subcategory of $\text{Fun}(N(M), \mathcal{C})$ spanned by those functors which satisfy the equivalent conditions of Proposition 5.5.5.7. The inclusions $M_0 \hookrightarrow M \leftrightarrow M_2$ determine restriction functors

$$\text{Shv}_X(X; \mathcal{C})^{\text{op}} \overset{\theta}{\leftarrow} \mathcal{E}(\mathcal{C})^{\text{op}} \overset{\theta'}{\rightarrow} \text{Shv}_X(X; \mathcal{C})^{\text{op}}.$$ 

Note that a functor $F \in \text{Fun}(N(M), \mathcal{C})$ belongs to $\mathcal{E}(\mathcal{C})$ if and only if $F|N(M_0)$ belongs to $\text{Shv}_X(X; \mathcal{C})^{\text{op}}$, $F|N(M_0 \cup M_1)$ is a right Kan extension of $F|N(M_0)$, and $F$ is a left Kan extension of $F|N(M_0 \cup M_1)$.

Applying Proposition T.4.3.2.15, we deduce that $\theta$ is a trivial Kan fibration. The same argument shows that $\theta'$ is a trivial Kan fibration, so that $\theta$ and $\theta'$ determine an equivalence $\text{Shv}_X(X; \mathcal{C})^{\text{op}} \simeq \text{Shv}_X(X; \mathcal{C})^{\text{op}}$. 

**Remark 5.5.5.8.** The construction $(i, S) \mapsto (2 - i, X - S)$ determines an order-reversing bijection from the partially ordered set $M$ to itself. Composition with this involution induces an isomorphism $\mathcal{E}(\mathcal{C})^{\text{op}} \simeq \mathcal{E}(\mathcal{C})^{\text{op}}$, which interchanges the restriction functors $\theta$ and $\theta'$ appearing in the proof of Theorem 5.5.5.4. It follows that the equivalence of Theorem 5.5.5.4 is symmetric in $\mathcal{C}$ and $\mathcal{C}^{\text{op}}$ (up to coherent homotopy).

We will give the proof of Proposition 5.5.5.7 at the end of this section. For the moment, we will concentrate on the problem of making the equivalence of Theorem 5.5.5.1 more explicit.

**Definition 5.5.5.9.** Let $X$ be a locally compact Hausdorff space and let $\mathcal{C}$ be a pointed $\infty$-category which admits small limits and colimits. Let $\mathcal{F}$ be a $\mathcal{C}$-valued sheaf on $X$. For every compact subset $K \subseteq X$, we let $\Gamma_K(X; \mathcal{F})$ denote the fiber product $\mathcal{F}(X) \times_{\mathcal{F}(X - K)} 0$, where 0 denotes a zero object of $\mathcal{C}$. For every open set $U \subseteq X$, we let $\Gamma_c(U; \mathcal{F})$ denote the filtered colimit $\lim_{\to K \subseteq U} \Gamma_K(M; \mathcal{F})$, where $\mathcal{K}$ ranges over all compact subsets of $U$. The construction $U \mapsto \Gamma_c(U; \mathcal{F})$ determines a functor $N(\mathcal{U}(X)) \to \mathcal{C}$, which we will denote by $\Gamma_c(\mathcal{U}; \mathcal{F})$.

**Proposition 5.5.5.10.** In the situation of Definition 5.5.5.9, suppose that the $\infty$-category $\mathcal{C}$ is stable. Then the equivalence $\mathbb{D}$ of Theorem 5.5.5.1 is given by the formula $\mathbb{D}(\mathcal{F})(U) = \Gamma_c(U; \mathcal{F})$. 
Remark 5.5.5.11. Proposition 5.5.5.10 is an abstract formulation of the following more classical fact: conjugation by Verdier duality exchanges cohomology with compactly supported cohomology.

Proof. It follows from the proof of Theorem T.7.3.4.9 that the equivalence
\[ \theta : \text{Shv}_X(X; \mathcal{E}^{op})^{op} \simeq \text{Shv}(X; \mathcal{E}^{op})^{op} \]
of Lemma 5.5.5.3 is given by the formula \( \theta(\mathcal{F})(U) = \lim_{K \subseteq U} S(K) \). Consequently, it will suffice to show that the composition of the equivalence \( \psi : \text{Shv}_X(X; \mathcal{E}) \rightarrow \text{Shv}_X(X; \mathcal{E}) \) of Lemma 5.5.5.3 with the equivalence \( \psi' : \text{Shv}_X(X; \mathcal{E}) \rightarrow \text{Shv}_X(X; \mathcal{E}^{op})^{op} \) is given by the formula \((\psi' \circ \psi)(\mathcal{F})(K) = \Gamma_K(X; \mathcal{F})\). To prove this, we need to introduce a bit of notation.

Let \( M' \) denote the partially ordered set of pairs \((i, S)\), where \( 0 \leq i \leq 2 \) and \( S \) is a subset of \( X \) such that \( S \) is compact if \( i = 0 \) and \( X - S \) is either open or compact if \( i = 2 \); we let \((i, S) \leq (j, T)\) if \( i \leq j \) and \( S \subseteq T \) or if \( i = 0 \) and \( j = 2 \). We will regard the set \( M \) of Notation 5.5.5.5 as a partially ordered subset of \( M' \).

For \( 0 \leq i \leq 2 \), let \( M_i' \) denote the subset \( \{(j, S) \in M' : j = i\} \subseteq M' \). Let \( \mathcal{D} \) denote the full subcategory of \( \text{Fun}(\text{N}(M'), \mathcal{E}) \) spanned by those functors \( F \) which satisfy the following conditions:

(i) The restriction \( F|\text{N}(M_2) \) is a \( \mathcal{X} \)-sheaf on \( X \).

(ii) The restriction \( F|\text{N}(M_2') \) is a right Kan extension of \( F|\text{N}(M_2) \).

(iii) The restriction \( F|\text{N}(M_1') \) is zero.

(iv) The restriction \( F|\text{N}(M') \) is a right Kan extension of \( F|\text{N}(M_1' \cup M_2') \).

Note that condition (ii) is equivalent to the requirement that \( F|\text{N}(M_1' \cup M_2') \) is a right Kan extension of \( F|\text{N}(M_1 \cup M_2) \). It follows from Proposition T.4.3.2.8 that condition (iv) is equivalent to the requirement that \( F|\text{N}(M) \) is a right Kan extension of \( F|\text{N}(M_1 \cup M_2) \). Consequently, the inclusion \( M \hookrightarrow M' \) induces a restriction functor \( \mathcal{D} \rightarrow \mathcal{E} \), where \( \mathcal{E} \subseteq \text{Fun}(\text{N}(M), \mathcal{E}) \) is defined as in the proof of Theorem 5.5.5.4. Using Theorem T.7.3.4.9 and Proposition T.4.3.2.15, we deduce that the restriction functor \( \mathcal{D} \rightarrow \text{Fun}(\text{N}(\Delta^1)_{op}, \mathcal{E}) \) is a trivial Kan fibration onto the full subcategory \( \text{Shv}_X(X; \mathcal{E}) \subseteq \text{Fun}(\text{N}(\Delta^1)_{op}, \mathcal{E}); \) moreover, the composition \( \psi' \circ \psi \) is given by composing a homotopy inverse of this trivial Kan fibration with the restriction functor \( \mathcal{D} \rightarrow \text{Fun}(\text{N}(M_0), \mathcal{E}) \simeq \text{Fun}(\text{N}(\Delta^1)_{op}, \mathcal{E}); \).

We define a map of simplicial sets \( \phi : \text{N}(M_0) \rightarrow \text{Fun}(\Delta^1 \times \Delta^1, \text{N}(M')) \) so that \( \phi \) carries an object \((0, K) \in M_0 \) to the diagram
\[
\begin{array}{ccc}
(0, K) & \longrightarrow & (1, K) \\
| & \downarrow & | \\
(2, \emptyset) & \longrightarrow & (2, K).
\end{array}
\]
It follows from Theorem T.4.1.3.1 that for each \((0, K) \in M_0 \), the image \( \phi(0, K) \) can be regarded as a left cofinal map \( \Lambda^2_2 \rightarrow \text{N}(M')_{(0,K)/} \times \text{N}(M') \text{N}(M_1' \cup M_2') \). Consequently, if \( F \in \mathcal{D} \) then condition (iv) is equivalent to the requirement that the composition of \( F \) with each \( \phi(0, K) \) yields a pullback diagram
\[
\begin{array}{ccc}
F(0, K) & \longrightarrow & F(1, K) \\
| & \downarrow & | \\
F(2, \emptyset) & \longrightarrow & F(2, K)
\end{array}
\]
in the \( \infty \)-category \( \mathcal{C} \). Since \( F(1, K) \) is a zero object of \( \mathcal{C} \) (condition (iii)), we can identify \( F(0, K) \) with the fiber of the map \( F(2, \emptyset) \rightarrow F(2, K) \). Taking \( F \) to be a preimage of \( \mathcal{F} \in \text{Shv}_X(X; \mathcal{E}) \) under the functor \( \theta \), we obtain the desired equivalence
\[
(\psi' \circ \psi)(\mathcal{F})(K) \simeq \text{fib}(\mathcal{F}(X) \rightarrow \mathcal{F}(X - K)) = \Gamma_K(X; \mathcal{F}).
\]
Corollary 5.5.5.12. Let $X$ be a locally compact Hausdorff space, let $\mathcal{C}$ be a stable $\infty$-category which admits small limits and colimits, and let $\mathcal{F} \in \text{Shv}(X; \mathcal{C})$ be a $\mathcal{C}$-valued sheaf on $X$. Then the functor $\Gamma_c(\bullet; \mathcal{F})$ is a $\mathcal{C}$-valued cosheaf on $X$.

We will need the following consequence of Corollary 5.5.5.12 in the next section.

Corollary 5.5.5.13. Let $M$ be a manifold and let $\mathcal{F} \in \text{Shv}(M; \text{Sp})$ be a $\text{Sp}$-valued sheaf on $M$. Then:

1. The functor $\mathcal{F}$ exhibits $\Gamma_c(M; \mathcal{F})$ as a colimit of the diagram $\{\Gamma_c(U; \mathcal{F})\}_{U \in \text{Disk}(M)}$.

2. The functor $\mathcal{F}$ exhibits $\Gamma_c(M; \mathcal{F})$ as a colimit of the diagram $\{\Gamma_c(U; \mathcal{F})\}_{U \in \text{Disj}(M)}$.

Proof. We will give the proof of (1); the proof of (2) is similar. According to Corollary 5.5.5.12, the functor $U \mapsto \Gamma_c(U; \mathcal{F})$ is a cosheaf of spectra on $M$. Since every open subset of $M$ is a paracompact topological space of finite covering dimension, the $\infty$-topos $\text{Shv}(M)$ is hypercomplete so that $\mathcal{F}$ is automatically hypercomplete. According to Remark 5.5.4.2, it will suffice to show that for every point $x \in M$, the category $\text{Disk}(M)_x = \{U \in \text{Disk}(M) : x \in U\}$ has weakly contractible nerve. This follows from the observation that $\text{Disk}(M)_x^{\text{op}}$ is filtered (since every open neighborhood of $M$ contains an open set $U \in \text{Disk}(M)_x$).

We conclude this section by giving the proof of Proposition 5.5.5.7.

Proof of Proposition 5.5.5.7. We will prove that condition (2) implies (1); the converse follows by symmetry, in view of Remark 5.5.5.8. Let $F : N(M) \to \mathcal{C}$ be a functor satisfying condition (2), and let $M'$ and $D \subseteq \text{Fun}(N(M'), \mathcal{C})$ be defined as in the proof of Proposition 5.5.5.10. Using Proposition T.4.3.2.15, we deduce that $F$ can be extended to a functor $F' : N(M') \to \mathcal{C}$ belonging to $D$. It follows from Theorem T.7.3.4.9 that the inclusion $U(X)^{\text{op}} \subseteq M'_2$ determines a restriction functor $D \to \text{Shv}(X; \mathcal{C})$; let $\mathcal{F} \in \text{Shv}(X; \mathcal{C})$ be the image of $F'$ under this restriction functor. The proof of Proposition 5.5.5.10 shows that $\mathcal{F} = F|N(M_0)$ is given informally by the formula $\mathcal{G}(K) = \Gamma_K(X; \mathcal{F})$.

We first show that $\mathcal{G}^{\text{op}}$ is a $\mathcal{C}^{\text{op}}$-valued $K$-sheaf on $X$. For this, we must verify the following:

(i) The object $\mathcal{G}(\emptyset) \simeq \Gamma_\emptyset(X; \mathcal{F})$ is zero. This is clear, since the restriction map $\mathcal{F}(X) \to \mathcal{F}(X - \emptyset)$ is an equivalence.

(ii) Let $K$ and $K'$ be compact subsets of $X$. Then the diagram $\sigma$:

\[
\begin{array}{ccc}
\mathcal{G}(K \cap K') & \longrightarrow & \mathcal{G}(K) \\
\downarrow & & \downarrow \\
\mathcal{G}(K') & \longrightarrow & \mathcal{G}(K \cup K')
\end{array}
\]

is a pushout square in $\mathcal{C}$. Since $\mathcal{C}$ is stable, this is equivalent to the requirement that $\sigma$ is a pullback square. This follows from the observation that $\sigma$ is the fiber of a map between the squares

\[
\begin{array}{ccc}
\mathcal{F}(X) & \longrightarrow & \mathcal{F}(X) \\
\downarrow & & \downarrow \\
\mathcal{F}(X) & \longrightarrow & \mathcal{F}(X - K)
\end{array}
\quad
\begin{array}{ccc}
\mathcal{F}(X) & \longrightarrow & \mathcal{F}(X) \\
\downarrow & & \downarrow \\
\mathcal{F}(X) & \longrightarrow & \mathcal{F}(X - K')
\end{array}
\quad
\begin{array}{ccc}
\mathcal{F}(X - (K \cap K')) & \longrightarrow & \mathcal{F}(X - K) \\
\downarrow & & \downarrow \\
\mathcal{F}(X - (K \cup K')) & \longrightarrow & \mathcal{F}(X - (K \cup K')).
\end{array}
\]

The left square is obviously a pullback, and the right is a pullback since $\mathcal{F}$ is a sheaf.

(iii) For every compact subset $K \subseteq X$, the canonical map $\theta : \mathcal{G}(K) \to \lim_{K'} \mathcal{G}(K')$ is an equivalence in $\mathcal{C}$, where $K'$ ranges over the partially ordered set $A$ of all compact subsets of $X$ which contain a
Proposition T.4.3.2.8, it suffices to prove the following: subset of $M$

to proving that the diagram

$\mathcal{F}(X - K) \xrightarrow{\theta''} \lim_{K' \in A} \mathcal{F}(X - K').$

It therefore suffices to show that $\theta'$ and $\theta''$ are equivalences. The map $\theta'$ is an equivalence because the partially ordered set $A$ has weakly contractible nerve (in fact, both $A$ and $A^{op}$ are filtered). The map $\theta''$ is an equivalence because $\mathcal{F}$ is a sheaf and the collection $\{X - K'\}_{K' \in A}$ is a covering sieve on $X - K$.

To complete the proof, we will show that $F$ is a left Kan extension of $F|N(M_0 \cup M_1)$. Let $M'' \subseteq M_0 \cup M_1$ be the subset consisting of objects of the form $(i, S)$, where $0 \leq i \leq 1$ and $S \subseteq X$ is compact. We note that $F|N(M_0 \cup M_1)$ is a left Kan extension of $F|N(M'')$. In view of Proposition T.4.3.2.8, it will suffice to show that $F$ is a left Kan extension of $F|N(M'')$ at every element $(2, S) \in M_2$. We will prove the stronger assertion that $F'|N(M'\cap M'_2)$ is a left Kan extension of $F|N(M'')$. To prove this, we let $B$ denote the subset of $M'_2$ consisting of pairs $(2, X - U)$ where $U \subseteq X$ is an open set with compact closure. In view of Proposition T.4.3.2.8, it suffices to prove the following:

(a) The functor $F'|N(M'\cup M'_2)$ is a left Kan extension of $F'|N(M'' \cup B)$.

(b) The functor $F'|N(M'' \cup B)$ is a left Kan extension of $F|N(M'')$.

To prove (a), we note that Theorem T.7.3.4.9 guarantees that $F'|N(M'_2)$ is a left Kan extension of $F'|N(M'')$ (note that, if $K$ is a compact subset of $X$, then the collection of open neighborhoods of $U$ of $K$ with compact closure is cofinal in the collection of all open neighborhoods of $K$ in $X$). To complete the proof, it suffices to observe that for every object $(2, X - K) \in M'_2 - B$, the inclusion $N(M'')(\langle 2, X - K \rangle) \subseteq N(M'' \cup M'_2)(\langle 2, X - K \rangle)$ is left cofinal. In view of Theorem T.4.1.3.1, this is equivalent to the requirement that for every object $(i, S) \in M''$, the partially ordered set $P = \{(2, X - U) \in B : (i, S) \leq (2, X - U) \leq (2, X - K)\}$ has weakly contractible nerve. This is clear, since $P$ is nonempty and stable under finite unions (and therefore filtered). This completes the proof of (a).

To prove (b), fix an open subset $U \subseteq X$ with compact closure; we wish to prove that $F'(2, X - U)$ is a colimit of the diagram $F'|N(M''(\langle 2, X - U \rangle))$. For every compact set $K \subseteq X$, let $M''_K$ denote the subset of $M''$ consisting of those pairs $(i, S)$ with $(0, K) \leq (i, S) \leq (2, X - U)$. Then $N(M''(\langle 2, X - U \rangle))$ is a filtered colimit of the simplicial sets $N(M''_K)$, where $K$ ranges over the collection of compact subsets of $X$ which contain $U$. It follows that $\operatorname{colim}(F'|N(M''))$ of $\operatorname{colim}(F'|N(M''_K))$ can be identified with the filtered colimit of the diagram

$$\{\operatorname{colim}(F'|N(M''_K))\}_{K}.$$

Consequently, it will suffice to prove that for every compact set $K$ containing $U$, the diagram $F'$ exhibits $F'(2, X - U)$ as a colimit of $F'|N(M''_K)$. Theorem T.4.1.3.1 guarantees that the diagram $(K, 0) \leftarrow (K - U, 0) \rightarrow (K - U, 1)$ is left cofinal in $N(M''_K)$. Consequently, we are reduced to proving that the diagram

$$F'(0, K) \rightarrow F'(1, K - U) \rightarrow F'(2, X - U).$$
is a pushout square in $\mathcal{C}$. Form a larger commutative diagram

$$
\begin{array}{c}
F'(0, K - U) \\
\downarrow \\
F'(0, K) \\
\downarrow \\
F(2, 0) \\
\downarrow \\
F(2, X - U)
\end{array}
\begin{array}{c}
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
F(1, K - U) \\
\downarrow \\
F(1, K) \\
\downarrow \\
F(2, K - U) \\
\downarrow \\
F(2, K)
\end{array}
$$

where the middle right square is a pullback. Since $F'$ is a right Kan extension of $F'|N(M_1 \cup M_2)$, the proof of Proposition 5.5.5.10 shows that the middle horizontal rectangle is also a pullback square. It follows that the lower middle square is a pullback. Since $\mathcal{C}$ is stable, we deduce that the upper left square is a pullback. Since $\mathcal{C}$ is stable, we deduce that the upper left square is a pushout diagram. To complete the proof of (b), it suffices to show that the composite map $Z \to F(2, K - U) \to F(2, X - U)$ is an equivalence. We note that $F(1, K - U)$ and $F(2, X) \simeq \mathcal{F}(\emptyset)$ are zero objects of $\mathcal{C}$, so the composite map $F(1, K - U) \to F(2, K) \to F(X)$ is an equivalence. It will therefore suffice to show that the right vertical rectangle is a pullback square. Since the middle right square is a pullback by construction, we are reduced to proving that the lower right square is a pullback. This is the diagram

$$
\begin{array}{c}
\mathcal{F}((X - K) \cup U) \\
\downarrow \\
\mathcal{F}(U) \\
\downarrow \\
\mathcal{F}(\emptyset),
\end{array}
\begin{array}{c}
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
\mathcal{F}(X - K) \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
$$

which is a pullback square because $\mathcal{F}$ is a sheaf and the open sets $U, X - K \subseteq X$ are disjoint.

5.5.6 Nonabelian Poincare Duality

Let $M$ be an oriented $k$-manifold. Poincare duality provides a canonical isomorphism

$$H^n_c(M; A) \simeq H_{k-n}(M; A)$$

for any abelian group $A$ (or, more generally, for any local system of abelian groups on $M$). Our goal in this section is to establish an analogue of this statement for nonabelian cohomology: that is, cohomology with coefficients in a local system of spaces on $M$. To formulate this analogue, we will need to replace the right hand side by the topological chiral homology $\int_M A$ of $M$ with coefficients in an appropriate $E_M$-algebra.

Remark 5.5.6.1. The ideas described in this section are closely related to results of Segal, McDuff, and Salvatore on configuration spaces (see [130], [110], and [123]). In particular, a special case of our main result (Theorem 5.5.6.6) can be found in [123].

Definition 5.5.6.2. Let $M$ be a manifold, and let $p : E \to M$ be a Serre fibration equipped with a distinguished section $s : M \to E$. Given a commutative diagram

$$
\begin{array}{c}
|\Delta^n| \times M \\
\downarrow f \\
E
\end{array}
\begin{array}{c}
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
M
\end{array}
$$

for any abelian group $A$ (or, more generally, for any local system of abelian groups on $M$). Our goal in this section is to establish an analogue of this statement for nonabelian cohomology: that is, cohomology with coefficients in a local system of spaces on $M$. To formulate this analogue, we will need to replace the right hand side by the topological chiral homology $\int_M A$ of $M$ with coefficients in an appropriate $E_M$-algebra.

Remark 5.5.6.1. The ideas described in this section are closely related to results of Segal, McDuff, and Salvatore on configuration spaces (see [130], [110], and [123]). In particular, a special case of our main result (Theorem 5.5.6.6) can be found in [123].

Definition 5.5.6.2. Let $M$ be a manifold, and let $p : E \to M$ be a Serre fibration equipped with a distinguished section $s : M \to E$. Given a commutative diagram

$$
\begin{array}{c}
|\Delta^n| \times M \\
\downarrow f \\
E
\end{array}
\begin{array}{c}
\rightarrow \\
\rightarrow \\
\rightarrow
\end{array}
\begin{array}{c}
M
\end{array}
$$
we will say that $f$ is trivial on an open set $U \subseteq M$ if the restriction $f|(|\Delta^n| \times U)$ is given by the composition

$$|\Delta^n| \times U \to U \subseteq M \xrightarrow{\delta} E.$$ 

We define the support of $f$ to be the smallest closed set $K$ such that $f$ is trivial on $M - K$. Given an open set $U \subseteq M$, we let $\Gamma(U; E)$ denote the simplicial set whose $n$-simplices are maps $f$ as above, and $\Gamma_c(U; E)$ the simplicial subset spanned by those simplices such that the support of $f$ is a compact subset of $U$ (in this case, $f$ is determined by its restriction $f|(|\Delta^n| \times U)$).

The construction $(U_1, \ldots, U_n) \mapsto \Gamma_c(U_1; E) \times \cdots \times \Gamma_c(U_n; E)$ determines a functor from $\mathcal{U}(M)^\otimes$ to the simplicial category of Kan complexes. Passing to nerves, we obtain a functor $N(\mathcal{U}(M)^\otimes) \to \mathcal{S}$, which we view as a $N(\mathcal{U}(M)^\otimes)$-monoid object of $\mathcal{S}$. Let us regard the $\infty$-category $\mathcal{S}$ as endowed with the Cartesian monoidal structure, so that this monoid object lifts in an essentially unique way to a $N(\mathcal{U}(M)^\otimes)$-algebra object of $\mathcal{S}$ (Proposition 2.4.2.5). We will denote this algebra by $E_t$.

**Remark 5.5.6.3.** Let $p : E \to M$ be as in Definition 5.5.6.2. Every inclusion of open disks $U \subseteq V$ in $M$ is isotopic to a homeomorphism (Theorem 5.4.1.5), so the inclusion $\Gamma_c(U; E) \to \Gamma_c(V; E)$ is a homotopy equivalence. It follows that the restriction $E|_1 N(\text{Disk}(M))^\otimes$ is a locally constant object of $\text{Alg}_{N(\text{Disk}(M))}(\mathcal{S})$, and is therefore equivalent to the restriction $E^t|_1 N(\text{Disk}(M))^\otimes$ for some essentially unique $\mathbb{E}_M$-algebra $E^t \in \text{Alg}_{\mathbb{E}_M}(\mathcal{S})$ (Theorem 5.4.5.9).

**Remark 5.5.6.4.** Let $M$ be a manifold and let $p : E \to M$ be a Serre fibration equipped with a section $s$. Then the functor $U \mapsto \Gamma(U; E)$ determines a sheaf $\mathcal{F}$ on $M$ with values in the $\infty$-category $\mathcal{S}$ of pointed spaces (Proposition T.7.1.3.14). Using Remark 5.5.6.14 and Lemma 5.5.6.15, we can identify the functor $U \mapsto \Gamma_c(U; \mathcal{F})$ of Definition 5.5.5.9 with the functor $U \mapsto \Gamma_c(U; E)$.

**Remark 5.5.6.5.** Let $p : E \to M$ be as in Definition 5.5.6.2. Since $p$ is a Serre fibration, the inverse image $U \times_M E$ is weakly homotopy equivalent to a product $U \times K$ for every open disk $\mathbb{R}^k \cong U \subseteq M$, for some pointed topological space $K$. For every positive real number $r$, let $X_r$ denote the simplicial subset of $\Gamma_c(U; E)$ whose $n$-simplices correspond to maps which are supported in the closed ball $B(r) \subseteq \mathbb{R}^k \approx U$. Then each $X_r$ is homotopy equivalent to the iterated loop space $\text{Sing}(\Omega^k K)$. Since there exist compactly supported isotopies of $\mathbb{R}^k$ carrying $B(r)$ to $B(s)$ for $0 < r < s$, we deduce that the inclusion $X_r \subseteq X_s$ is a homotopy equivalence for each $r < s$. It follows that $\Gamma_c(U; E) = \lim_{r \to 0} X_r$ is weakly homotopy equivalent to $X_r$ for every real number $r$.

In other words, we can think of $E^t|_1 \mathbb{E}_M^\otimes \to \mathcal{S}^\times$ as an algebra which assigns to each open disk $j : U \hookrightarrow M$ the $k$-fold loop space of $F$, where $F$ is the fiber of the Serre fibration $p : E \to M$ over any point in the image of $j$.

We can now state our main result as follows:

**Theorem 5.5.6.6** (Nonabelian Poincare Duality). Let $M$ be a $k$-manifold, and let $p : E \to M$ be a Serre fibration whose fibers are $k$-connective, which is equipped with a section $s : M \to E$. Then $E_t$ exhibits $\Gamma_c(M; E)$ as the colimit of the diagram $E|_1 N(\text{Disj}(M))$. In other words, $\Gamma_c(M; E)$ is the topological chiral homology $\int_M E^t$, where $E^t \in \text{Alg}_{\mathbb{E}_M}(\mathcal{S})$ is the algebra described in Remark 5.5.6.3.

**Remark 5.5.6.7.** The assumption that $p : E \to M$ have $k$-connective fibers is essential. For example, suppose that $E = M \coprod M$ and that the section $s : M \to E$ is given by the inclusion of the second factor. If $M$ is compact, then the inclusion of the second factor determines a vertex $\eta \in \Gamma_c(M; E)$. The support of $\eta$ is the whole of the manifold $M$: in particular, $\eta$ does not lie in the essential image of any of the extension maps $i : \Gamma_c(U; E) \to \Gamma_c(M; E)$ where $U$ is a proper open subset of $M$. In particular, if $U$ is a disjoint union of open disks, then $\eta$ cannot lie in the essential image of $i$ unless $k = 0$ or $M$ is empty.

**Remark 5.5.6.8.** Theorem 5.5.6.6 implies in particular that any compactly supported section $s'$ of $p : E \to M$ is homotopic to a section whose support is contained in the union of disjoint disks in $M$. It is easy to see this directly, at least when $M$ admits a triangulation. Indeed, let $M_0 \subseteq M$ be the $(k - 1)$-skeleton of this
triangulation, so that the open set $M - M_0$ consists of the interiors of the $k$-simplices of the triangulation and is thus a union of disjoint open disks in $M$. Since the fibers of $p$ are $k$-connective, the space of sections of $p$ over the $(k-1)$-dimensional space $M_0$ is connected. Consequently, we can adjust $s'$ by a homotopy so that it agrees with $s$ on a small neighborhood of $M_0$ in $M$, and is therefore supported in $M - M_0$.

**Remark 5.5.6.9.** Theorem 5.5.6.6 can be rephrased in terms of the *embedding calculus* developed by Weiss (see [161]). Let $p : E \to M$ be a Serre fibration, and regard the functor $U \mapsto \Gamma_c(U; E)$ as a presheaf $\mathcal{F}$ on $M$ with values in $\text{Set}_\Delta$. Applying the formalism of the embedding calculus, we obtain a sequence of polynomial approximations

$$\mathcal{F}^{≤0} \to \mathcal{F}^{≤1} \to \mathcal{F}^{≤2} \to \cdots,$$

where each $\mathcal{F}^{≤n}$ is a left Kan extension of the restriction of $\mathcal{F}$ to those open subsets of $M$ which are homeomorphic to a union of at most $n$ disks. Theorem 5.5.6.6 asserts that, when the fibers of $p$ are sufficiently connected, the canonical map

$$\text{hocolim}_n \mathcal{F}^{≤n} \to \mathcal{F}$$

is a weak equivalence. In other words, the functor $U \mapsto \Gamma_c(U; E)$ can be recovered as the limit of its polynomial approximations.

**Example 5.5.6.10.** Let $M$ be the circle $S^1$, let $X$ be a connected pointed space, and let $E = X \times S^1$, equipped with the projection map $p : E \to M$. Then $E^1 \in \text{Alg}_{E^1}(S)$ is the $E_{S^1}$-algebra determined by the singular complex of the space $LX = \text{Map}(S^1, X)$ of all sections of $p$. In view of Example 5.5.3.14, Theorem 5.5.6.6 recovers the following classical observation: the free loop space $LX$ is equivalent to the Hochschild homology of the based loop space $\Omega X$ (regarded as an associative algebra with respect to composition of loops).

**Remark 5.5.6.11.** Let $M$ be a $k$-manifold. We will say than an algebra $A \in \text{Alg}_{E_k}(S)$ is *grouplike* if, for every open disk $U \subseteq M$, the restriction $A|\overline{E}_U \in \text{Alg}_{\overline{E}_k}(S) \simeq \text{Alg}_{E_k}(S)$ is grouplike in the sense of Definition 5.2.6.6 (by convention, this condition is vacuous if $k = 0$). For every fibration $E \to M$, the associated algebra $E^1 \in \text{Alg}_{E_k}(S)$ is grouplike. In fact, the converse holds as well: every grouplike object of $\text{Alg}_{E_k}(S)$ has the form $E^1$, for an essentially unique Serre fibration $E \to M$ with $k$-connective fibers.

To prove this, we need to introduce a bit of notation. For each open set $U \subseteq M$, let $\mathcal{A}_U$ denote the simplicial category whose objects are Serre fibrations $p : E \to U$ equipped with a section $s$, where the pair $(U, E)$ is a relative CW complex and the fibers of $p$ are $k$-connective; an $n$-simplex of $\text{Map}_{\mathcal{A}_U}(E, E')$ is a commutative diagram

$$
\begin{align*}
\begin{array}{ccc}
E \times \Delta^n & \xrightarrow{f} & E' \\
\downarrow p & & \downarrow p' \\
U & \xrightarrow{s} & U.
\end{array}
\end{align*}
$$

such that $f$ respects the preferred sections of $p$ and $p'$. Let $\mathcal{B}_U$ denote the full subcategory of $\text{Alg}_{E_k}(S)$ spanned by the grouplike objects. The construction $E \mapsto E^1$ determines a functor $\theta_U : \mathcal{A}_U \to \mathcal{B}_U$, which we claim is an equivalence of $\infty$-categories. If $U \simeq \mathbb{R}^k$ is an open disk in $M$, then this assertion follows from Theorem 5.2.6.15 (at least if $k > 0$; the case $k = 0$ is trivial). Let $\mathcal{J}$ denote the collection of all open subsets $U \subseteq M$ which are homeomorphic to $\mathbb{R}^k$, partially ordered by inclusion. This collection of open sets satisfies the following condition:

(*) For every point $x \in M$, the subset $\mathcal{J}_x = \{ U \in \mathcal{J} : x \in U \}$ has weakly contractible nerve (in fact, $\mathcal{J}_x^{op}$ is filtered, since every open subset of $M$ containing $x$ contains an open disk around $x$).
We have a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
N(A_M) & \xrightarrow{\theta_M} & B_M \\
\phi \downarrow & & \downarrow \psi \\
\varprojlim_{U \in \mathcal{E}_\infty} N(A_U) & \xrightarrow{=} & \varprojlim_{U \in \mathcal{E}_\infty} B_U
\end{array}
\]

(here the limits are taken in the \( \infty \)-category \( \text{Cat}_{\infty} \)). Here the lower horizontal map is an equivalence of \( \infty \)-categories. Consequently, to prove that \( \theta_M \) is an equivalence of \( \infty \)-categories, it suffices to show that the vertical maps are equivalences of \( \infty \)-categories. We consider each in turn.

For each \( U \subseteq M \), let \( \mathcal{C}_U \) denote the simplicial category whose objects are Kan fibrations \( p : X \rightarrow \text{Sing}(U) \). The functor \( E \mapsto \text{Sing}(E) \) determines an equivalence of \( \infty \)-categories \( N(A_U) \rightarrow N(\mathcal{C}_U)_\ast \). Consequently, to show that \( \phi \) is a categorical equivalence, it will suffice to show that the associated map \( N(\mathcal{C}_M) \rightarrow \varprojlim_{U \in \mathcal{E}_\infty} N(\mathcal{C}_U) \) is a categorical equivalence. This is equivalent to the requirement that \( \text{Sing}(M) \) is a colimit of the diagram \( \{ \text{Sing}(U) \}_{U \in \mathcal{E}_\infty} \) in the \( \infty \)-category \( \mathcal{S} \), which follows from (*) and Theorem A.3.1.

To prove that \( \psi \) is a categorical equivalence, it suffices to show that \( \text{Alg}_{\mathcal{E}_M}(\mathcal{S}) \) is a limit of the diagram \( \{ \text{Alg}_{\mathcal{E}_U}(\mathcal{S}) \}_{U \in \mathcal{E}_\infty} \). For each \( U \subseteq M \), let \( \mathcal{D}_U \) denote the \( \infty \)-category \( \text{Alg}_{\mathcal{O}_U}(\mathcal{S}) \), where \( \mathcal{O}_U^\otimes \) denotes the generalized \( \infty \)-operad \( B_{\text{Top}}(k)^\otimes \times_{B_{\text{Top}}(k)} (B_U \times N(\text{Fin}_\ast)) \). It follows that the restriction functor \( A \mapsto A|_{\mathcal{O}_U^\otimes} \) determines an equivalence of \( \infty \)-categories \( \text{Alg}_{\mathcal{E}_U}(\mathcal{S}) \rightarrow \mathcal{D}_U \). It will therefore suffice to show that \( \mathcal{D}_M \) is a limit of the diagram of \( \infty \)-categories \( \{ \mathcal{D}_U \}_{U \in \mathcal{E}_\infty} \). To prove this, we show that the functor \( U \mapsto \mathcal{O}_U^\otimes \) exhibits the generalized \( \infty \)-operad \( \mathcal{O}_M^\otimes \) as a homotopy colimit of the generalized \( \infty \)-operads \( \{ \mathcal{O}_U^\otimes \}_{U \in \mathcal{E}_\infty} \). For this, it is sufficient to show that the Kan complex \( B_M \) is a homotopy colimit of the diagram \( \{ B_U \}_{U \in \mathcal{E}_\infty} \), which follows from Remark 5.5.5.2, (*), and Theorem A.3.1.

**Remark 5.5.6.12.** In proving Theorem 5.5.6.6, it is sufficient to treat the case where the manifold \( M \) is connected. To see this, we note that for every open set \( U \subseteq M \), we have a map \( \theta_U : U \rightarrow \mathcal{O}_c(U; E) \). Assume that \( \theta_U \) is a homotopy equivalence whenever \( U \) is connected. We will prove that \( \theta_U \) is a homotopy equivalence whenever the set of connected components \( \pi_0(U) \) is finite. It will then follow that \( \theta_U \) is an equivalence for every open set \( U \subseteq M \), since the construction \( U \mapsto \theta_U \) commutes with filtered colimits; in particular, it will follow that \( \theta_M \) is a homotopy equivalence.

To carry out the argument, let \( U \subseteq M \) be an open set with finitely many connected components \( U_1, \ldots, U_n \), so that we have a commutative diagram

\[
\begin{array}{ccc}
\prod_{1 \leq i \leq n} \int_{U_i} E^i & \xrightarrow{\theta_{U_1} \times \cdots \times \theta_{U_n}} & \prod_{1 \leq i \leq n} \Gamma_c(U_i, E) \\
\phi \downarrow & & \downarrow \psi \\
\int_U E & \xrightarrow{\theta_U} & \Gamma_c(U, E)
\end{array}
\]

The map \( \theta_{U_1} \times \cdots \times \theta_{U_n} \) is a homotopy equivalence since each \( U_i \) is connected, the map \( \phi \) is a homotopy equivalence by Theorem 5.5.3.1, and the map \( \psi \) is an isomorphism of Kan complexes; it follows that \( \theta_U \) is a homotopy equivalence as desired.

**Notation 5.5.6.13.** Let \( p : E \rightarrow M \) be as in Definition 5.5.6.2. Given a compact set \( K \subseteq M \), we let \( \Gamma_K(M; E) \) denote the simplicial set whose \( n \)-simplices are commutative diagrams

\[
\begin{array}{ccc}
(|\Delta^n| \times M) \coprod_{|\Delta^n| \times (M - K) \times \{0\}} (|\Delta^n| \times (M - K) \times [0, 1]) & \xleftarrow{f} & E \\
& \downarrow p & \downarrow \\
& M & \rightarrow
\end{array}
\]
such that $f|(|\Delta^n| \times (M - K) \times \{1\})$ is given by the composition

$$|\Delta^n| \times V \times \{1\} \to (M - K) \subseteq M \xrightarrow{\Delta} E.$$  

In other words, an $n$-simplex of $\Gamma_K(M; E)$ is an $n$-parameter family of sections of $E$, together with a nullhomotopy of this family of sections on the open set $M - K$.

Note that any $n$-simplex of $\Gamma_\circ(M; E)$ which is trivial on $M - K$ extends canonically to an $n$-simplex of $\Gamma_K(M; E)$, by choosing the nullhomotopy to be constant. In particular, if $U \subseteq M$ is any open set, then we obtain a canonical map

$$\Gamma_\circ(U; E) \to \lim_{K \subseteq U} \Gamma_K(M; E),$$

where the colimit is taken over the (filtered) collection of all compact subsets of $U$.

**Remark 5.5.6.14.** The simplicial set $\Gamma_K(M; E)$ can be identified with the homotopy fiber of the restriction map $\mathcal{F}(M) \to \mathcal{F}(M - K)$, where $\mathcal{F} \in \text{Shv}(M)$ is the sheaf associated to the fibration $p : E \to M$.

**Lemma 5.5.6.15.** Let $p : E \to M$ be a Serre fibration equipped with a section $s$ (as in Definition 5.5.6.2), let $U \subseteq M$ be an open set. Then the canonical map

$$\Gamma_\circ(U; E) \to \lim_{K \subseteq U} \Gamma_K(M; E)$$

is a homotopy equivalence.

**Proof.** It will suffice to show that if $A \subseteq B$ is an inclusion of finite simplicial sets and we are given a commutative diagram

$$
\begin{array}{ccc}
A & \longrightarrow & \Gamma_\circ(U; E) \\
\downarrow & & \downarrow \\
B & \xrightarrow{f} & \lim_{K \subseteq U} \Gamma_K(M; E), \\
\end{array}
$$

then, after modifying $f$ by a homotopy that is constant on $A$, there exists a dotted arrow $f'$ as indicated in the diagram (automatically unique, since the right vertical map is a monomorphism). Since $B$ is finite, we may assume that $f$ factors through $\Gamma_K(M; E)$ for some compact subset $K \subseteq U$. Such a factorization determines a pair $(\bar{F}, h)$, where $F : [B] \times M \to E$ is a map of spaces over $M$ and $h : [B] \times (M - K) \times [0, 1] \to E$ is a fiberwise homotopy of $F([|B| \times (M - K)])$ to the composite map $[B] \times (M - K) \to M \xrightarrow{s} E$. Choose a continuous map $\lambda : M \to [0, 1]$ which is supported in a compact subset $K'$ of $U$ and takes the value 1 in a neighborhood of $K$. Let $F' : [B] \times M \to E$ be the map defined by the formula

$$F'(b, x) = \begin{cases} 
F(b, x) & \text{if } x \in K \\
h(b, x, 1 - \lambda(x)) & \text{if } x \notin K.
\end{cases}$$

Then $F'$ determines a map $B \to \Gamma_\circ(U; E)$ such that the composite map $B \to \Gamma_\circ(U; E) \to \lim_{\mathcal{F} \subseteq U} \Gamma_K(M; E)$ is homotopic to $f$ relative to $A$, as desired. \qed

We now proceed with the proof of Theorem 5.5.6.6. If $M$ is homeomorphic to Euclidean space $\mathbb{R}^k$, then $\text{Disj}(M)$ contains $M$ as a final object and Theorem 5.5.6.6 is obvious. Combining this observation with Remark 5.5.6.12, we obtain an immediate proof in the case $k = 0$. If $k = 1$, then we may assume (by virtue of Remark 5.5.6.12) that $M$ is homeomorphic to either an open interval (in which case there is nothing to prove) or to the circle $S^1$. The latter case requires some argument:
Proof of Theorem 5.5.6.6 for $M = S^1$. Choose a small open disk $U \subseteq S^1$ and a parametrization $\psi : \mathbb{R} \simeq U$, and let $\chi : D(S^1)/\psi \to S$ be the diagram determined by $E'$. According to Theorem 5.5.3.11, the functor $\chi$ is equivalent to a composition $D(S^1)/\psi \to N(\Delta^0) \mathcal{B}_S$ for some simplicial object $B_\bullet$ of $\mathcal{S}$, and the topological chiral homology $\int_{S^1} E'$ can be identified with the geometric realization $|B_\bullet|$. We wish to show that the canonical map $\theta : |B_\bullet| \to \Gamma_c(S^1;E)$ is an equivalence in $\mathcal{S}$. Since $\mathcal{S}$ is an $\infty$-topos, it will suffice to verify the following pair of assertions:

(a) The map $\theta_0 : B_0 \to \Gamma_c(S^1;E)$ is an effective epimorphism. In other words, $\theta_0$ induces a surjection $\pi_0 B_0 = \pi_0 \Gamma_c(U;E) \to \pi_0 \Gamma_c(S^1;E)$.

(b) The map $\theta$ exhibits $B_\bullet$ as a Čech nerve of $\theta_0$. That is, for each $n \geq 0$, the canonical map

$$B_n \to B_0 \times_{\Gamma_c(S^1;E)} \cdots \times_{\Gamma_c(S^1;E)} B_0$$

is a homotopy equivalence (here the fiber products are taken in the $\infty$-category $\mathcal{S}$).

To prove (a), let $s : S^1 \to E$ denote our given section of the Serre fibration $p : E \to S^1$, and let $f : S^1 \to E$ denote any other section of $p$. Choose a point $x \in U$. Since $S^1 - \{x\}$ is contractible and the fibers of $p$ are connected, there exists a (fiberwise) homotopy $h : (S^1 - \{x\}) \times [0,1] \to E$ from $f|(S^1 - \{x\})$ to $s)|(S^1 - \{x\})$. Let $\lambda : S^1 \to [0,1]$ be a continuous function which vanishes in a neighborhood of $x$, and takes the value 1 outside a compact subset of $U$. Let $h' : S^1 \times [0,1] \to E$ be the map defined by

$$h'(y,t) = \begin{cases} f(x) & \text{if } y = x \\ h(y, \lambda(y)) & \text{if } y \neq x. \end{cases}$$

Then $h'$ determines a homotopy from $f$ to another section $f' = h'|(S^1 \times \{1\})$, whose support is a compact subset of $U$.

We now prove (b). Choose a collection of open disks $U_1, \ldots, U_n \subseteq S^1$ which are disjoint from one another and from $U$. Then the closed set $S^1 - (U \cup U_1 \cup \ldots \cup U_n)$ is a disjoint union of connected components $A_0, \ldots, A_n$. Unwinding the definitions, we are required to show that the simplicial set $\Gamma_c(U \cup U_1 \cup \ldots \cup U_n;E)$ is a homotopy product of the simplicial sets $\Gamma_c(S^1 - A_i;E)$ in the model category $(\text{Set}_\Delta)_{\Gamma_c(S^1;E)}$. For each index $i$, let $U_i$ denote the collection of all open subsets of $S^1$ that contain $A_i$, and let $U = \bigcap U_i$. It follows from Lemma 5.5.6.15 that we have canonical homotopy equivalences

$$\Gamma_c(S^1 - A_i;E) \to \lim_{V \in U_i} \Gamma_{S^1 - V}(S^1;E)$$

$$\Gamma_c(U \cup U_1 \cup \ldots \cup U_n;E) \to \lim_{V \in U} \Gamma_{S^1 - V}(S^1;E).$$

Note that for each $V \in U_i$, the forgetful map $\Gamma_{S^1 - V}(S^1;E) \to \Gamma_c(S^1;E)$ is a Kan fibration. It follows that each $\lim_{V \in U} \Gamma_{S^1 - V}(S^1;E)$ is a fibrant object of $(\text{Set}_\Delta)_{\Gamma_c(S^1;E)}$, so the relevant homotopy product coincides with the actual product $\prod_{0 \leq i \leq n} \lim_{V_i \in U_i} \Gamma_{S^1 - V_i}(S^1;E)$ (formed in the category $(\text{Set}_\Delta)_{\Gamma_c(S^1;E)}$).

Let $V$ denote the partially ordered set of sequences $(V_0, \ldots, V_n) \in U_0 \times \cdots \times U_n$ such that $V_i \cap V_j = \emptyset$ for $i \neq j$. We observe that the inclusion $V \subseteq (U_0 \times \cdots \times U_n)$ is right cofinal, and the construction $(V_0, \ldots, V_n) \mapsto \bigcup V_i$ is a right cofinal map from $V$ to $U$. Consequently, we obtain isomorphisms

$$\lim_{V \in \mathcal{U}} \Gamma_{S^1 - V}(S^1;E) \simeq \lim_{(V_0, \ldots, V_n) \in V} \Gamma_{S^1 - \bigcup V_i}(S^1;E)$$

$$\prod_{0 \leq i \leq n} \Gamma_{S^1 - V_i}(S^1;E) \simeq \lim_{(V_0, \ldots, V_n) \in V} \prod_{0 \leq i \leq n} \Gamma_{S^1 - V_i}(S^1;E);$$
In other words, the fiber product \( X \) is a homotopy equivalence.

We now complete the proof by observing that \( \theta \) is an isomorphism (since the open sets \( V_i \) are assumed to be pairwise disjoint).

Our proof of Theorem 5.5.6.6 in higher dimensions will use a rather different method. We first consider the following linear version of Theorem 5.5.6.6, which is an easy consequence of the version of Verdier duality presented in \( \S \).

**Proposition 5.5.6.16.** Let \( M \) be a \( k \)-manifold, let \( \mathcal{F} \in \text{Shv}(M; \text{Sp}) \) be a locally constant \( \text{Sp} \)-valued sheaf on \( M \), and let \( \mathcal{F}' \in \text{Shv}(M; \text{Sp}_*) \) be the sheaf of pointed spaces given by the formula \( \mathcal{F}'(U) = \Omega_*^\infty \mathcal{F}(U) \). Assume that for every open disk \( U \subseteq M \), the spectrum \( \mathcal{F}(U) \) is \( k \)-connective. Then \( \mathcal{F}' \) exhibits \( \Gamma_*(M; \mathcal{F}') \) as a colimit of the diagram \( \{ \Gamma_*(U; \mathcal{F}') \}_{U \in \text{Disj}(M)} \) in the \( \infty \)-category \( \text{Sp}_* \).

**Proof.** It follows from Corollary 5.5.5.13 that \( \mathcal{F} \) exhibits \( \Gamma_*(M; \mathcal{F}) \) as a colimit of the diagram

\[
\{ \Gamma_*(U; \mathcal{F}) \}_{U \in \text{Disj}(M)}
\]

in the \( \infty \)-category \( \text{Sp} \) of spectra. It will therefore suffice to show that the functor \( \Omega_*^\infty \) preserves the colimit of the diagram \( \{ \Gamma_*(U; \mathcal{F}) \}_{U \in \text{Disj}(M)} \).

Let us regard the \( \infty \)-category \( \text{Sp} \) as endowed with its Cartesian symmetric monoidal structure, which (by virtue of Proposition 2.4.3.19) is also the coCartesian symmetric monoidal structure. The functor \( U \mapsto \Gamma_*(U; \mathcal{F}) \) determines a functor \( \text{N}(\text{Disk}(M)) \to \text{Sp} \), which extends to a map of \( \infty \)-operads \( \text{N}(\text{Disk}(M))^\otimes \to \text{Sp}^\infty \) and therefore determines an algebra \( A \in \text{Alg}_{\text{N}(\text{Disk}(M))}^\otimes (\text{Sp}) \). Since \( \mathcal{F} \) is locally constant, the algebra \( A \) is locally constant and is therefore equivalent to a composition

\[
\text{N}(\text{Disk}(M))^\otimes \to \mathbb{E}_M^\otimes \xrightarrow{B} \text{Sp}^\infty.
\]

Let \( A' : \text{N}(\text{Disk}(M))^\otimes \to \text{Sp} \) and \( B' : E_M \to \text{Sp} \) be the associated monoid objects of \( \text{Sp} \) (see Proposition 2.4.2.5). We wish to show that \( \Omega_*^\infty \) preserves the colimit of the diagram \( \{ A'(U) \}_{U \in \text{Disj}(M)} \). In view of Proposition 5.5.2.13, it will suffice to prove that \( \Omega_*^\infty \) preserves the colimit of the diagram \( B' \text{D}(M) \). For every open set \( U = U_1 \cup \ldots \cup U_n \) of \( \text{D}(M) \), the spectrum \( B'(U) \simeq \prod_{1 \leq i \leq n} B'(U_i) \simeq \prod_{1 \leq i \leq n} \Omega_*^\infty \mathcal{F}(U_i) \) is connected. Since the \( \infty \)-category \( \text{D}(M) \) is sifted (Proposition 5.5.2.13), the desired result follows from Corollary 5.2.6.27.

Recall that if \( X \) is an \( \infty \)-topos, then colimits in \( X \) are universal: that is, for every morphism \( f : X \to Y \) in \( X \), the fiber product construction \( Z \mapsto X \times_Y Z \) determines a colimit-preserving functor from \( X/_{/Y} \) to \( X/_{/X} \). In other words, the fiber product \( X \times_Y Z \) is a colimit-preserving functor of \( Z \). The same argument shows that \( X \times_Y Z \) is a colimit-preserving functor of \( Z \). However, the dependence of the fiber product \( X \times_Y Z \) on \( Y \) is more subtle. The following result, which asserts that the construction \( Y \mapsto X \times_Y Z \) commutes with colimits in many situations.

**Lemma 5.5.6.17.** Let \( X \) be an \( \infty \)-topos, and let \( X_*^{\geq 1} \) denote the full subcategory of \( X_* \) spanned by the pointed connected objects. Let \( \mathcal{C} \) denote the \( \infty \)-category \( \text{Fun}(\Lambda_2^1, X) \times_{\text{Fun}(\{2\}, X)} X_*^{\geq 1} \) whose objects are diagrams \( X \to Z \leftarrow Y \) in \( X \), where \( Z \) is a pointed connected object of \( X \). Let \( F : \mathcal{C} \to X \) be the functor

\[
\mathcal{C} \to \text{Fun}(\Lambda_2^1, X) \xrightarrow{\text{lim}} X
\]

given informally by the formula \( (X \to Z \leftarrow Y) \mapsto X \times_Z Y \). The \( F \) preserves sifted colimits.
Proof. Let $\mathcal{C}'$ denote the full subcategory of $\text{Fun}(\Delta^1 \times \Delta^1 \times N(\Delta^\text{op}), \mathcal{X})$ spanned by those functors $G$ which corresponding to diagrams of augmented simplicial objects

\[
\begin{array}{ccc}
W_\bullet & \longrightarrow & X_\bullet \\
\downarrow & & \downarrow \\
Y_\bullet & \longrightarrow & Z_\bullet
\end{array}
\]

which satisfy the following conditions:

(i) The object $Z_0$ is final.

(ii) The augmentation map $Z_0 \to Z_{-1}$ is an effective epimorphism (equivalently, $Z_{-1}$ is a connected object of $\mathcal{X}$).

(iii) Let $K$ denote the full subcategory of $\Delta^1 \times \Delta^1 \times N(\Delta^\text{op})$ spanned by the objects $(1, 0, [-1])$, $(0, 1, [-1])$, $(1, 1, [-1])$, and $(1, 1, [0])$. Then $G$ is a right Kan extension of $G|_K$. In particular, the diagram

\[
\begin{array}{ccc}
W_{-1} & \longrightarrow & X_{-1} \\
\downarrow & & \downarrow \\
Y_{-1} & \longrightarrow & Z_{-1}
\end{array}
\]

is a pullback square.

It follows from Proposition T.4.3.2.15 that the restriction map $G \mapsto G|_K$ induces a trivial Kan fibration $q : \mathcal{C}' \to \mathcal{C}$. Note that the functor $F$ is given by composing a section of $q$ with the evaluation functor $G \mapsto G(0, 0, [-1])$. To prove that $F$ commutes with sifted colimits, it will suffice to show that $\mathcal{C}'$ is stable under sifted colimits in $\text{Fun}(\Delta^1 \times \Delta^1 \times N(\Delta^\text{op}), \mathcal{X})$.

Let $\mathcal{D}$ be the full subcategory of $\text{Fun}(\Delta^1 \times \Delta^1 \times N(\Delta^\text{op}), \mathcal{X})$ spanned by those diagrams of simplicial objects

\[
\begin{array}{ccc}
W_\bullet & \longrightarrow & X_\bullet \\
\downarrow & & \downarrow \\
Y_\bullet & \longrightarrow & Z_\bullet
\end{array}
\]

satisfying the following conditions:

(i') The simplicial object $Z_\bullet$ is a group object of $\mathcal{X}$ (that is, $Z_\bullet$ is a groupoid object of $\mathcal{X}$ and $Z_0$ is final in $\mathcal{X}$; equivalently, for each $n \geq 0$ the natural map $Z_n \to Z_1^n$ is an equivalence).

(ii') For each integer $n$ and each inclusion $[0] \hookrightarrow [n]$, the induced maps

\[
X_n \to X_0 \times Z_n \quad Y_n \to Y_0 \times Z_n \quad W_n \to X_0 \times Y_0 \times Z_n
\]

are equivalences.

Since the product functor $\mathcal{X} \times \mathcal{X} \to \mathcal{X}$ commutes with sifted colimits (Proposition T.5.5.8.6), we deduce that $\mathcal{D}$ is stable under sifted colimits in $\text{Fun}(\Delta^1 \times \Delta^1 \times N(\Delta^\text{op}), \mathcal{X})$. Let $\mathcal{D}' \subseteq \text{Fun}(\Delta^1 \times \Delta^1 \times N(\Delta^\text{op}), \mathcal{X})$ be the full subcategory spanned by those functors $G$ such that $G$ is a left Kan extension of $G_0 = G|_0 \Delta^1 \times \Delta^1 \times N(\Delta^\text{op}))$ and $G_0 \in \mathcal{D}$. Then $\mathcal{D}'$ is stable under sifted colimits in $\text{Fun}(\Delta^1 \times \Delta^1 \times N(\Delta^\text{op}), \mathcal{X})$. We will complete the proof by showing that $\mathcal{D}' = \mathcal{C}'$. 
Suppose first that \( G \in \mathcal{C}' \), corresponding to a commutative diagram of augmented simplicial objects

\[
\begin{array}{ccc}
W_n & \longrightarrow & X_n \\
\downarrow & & \downarrow \\
Y_n & \longrightarrow & Z_n
\end{array}
\]

Condition (iii) guarantees that \( Z_n \) is a Čech nerve of the augmentation map \( Z_0 \rightarrow Z_{-1} \). Since this augmentation map is an effective epimorphism (by virtue of (ii)), we deduce that the augmented simplicial object \( Z_n \) is a colimit diagram. Condition (iii) guarantees that the natural maps \( X_n \rightarrow Z_n \times_{Z_{-1}} X_{-1} \) is are equivalences. Since colimits in \( \mathcal{X} \) are universal, we deduce that \( X_n \) is also a colimit diagram. The same argument shows that \( Y_n \) and \( W_n \) are colimit diagrams, so that \( G \) is a left Kan extension of \( G_0 = G|\{\Delta^1 \times \Delta^1 \times N(\Delta^{op})\} \). To complete the proof that \( G \in \mathcal{D}' \), it suffices to show that \( G_0 \) satisfies conditions (i′) and (ii′). Condition (i′) follows easily from (i) and (iii), and condition (ii′) follows from (iii).

Conversely, suppose that \( G \in \mathcal{D}' \); we wish to show that \( G \) satisfies conditions (i), (ii), and (iii). Condition (i) follows immediately from (i′), and condition (ii) from the fact that \( Z_n \) is a colimit diagram. It remains to prove (iii). Let \( K' \) denote the full subcategory of \( \Delta^1 \times \Delta^1 \times N(\Delta^{op}) \) spanned by the objects \((0,1,[-1]), (1,0,[-1]),\) and \(\{(1,1,[n])\}_{n \geq -1} \). Since \( \mathcal{X} \) is an \( \infty \)-topos and \( Z_n \) is the colimit of a groupoid object of \( \mathcal{X} \), it is a Čech nerve of the augmentation map \( Z_0 \rightarrow Z_{-1} \). This immediately implies that \( G|K' \) is a right Kan extension of \( G|K \). To complete the proof, it will suffice to show that \( G \) is a right Kan extension of \( G|K' \) (Proposition T.4.3.2.8).

We first claim that \( G \) is a right Kan extension of \( G|K' \) at \((0,1,[n])\) for each \( n \geq 0 \). Equivalently, we claim that each of the maps

\[
\begin{array}{ccc}
X_n & \longrightarrow & X_{-1} \\
\downarrow & & \downarrow \\
Z_n & \longrightarrow & Z_{-1}
\end{array}
\]

is a pullback diagram. Since \( X_n \) and \( Z_n \) are both colimit diagrams, it will suffice to show that the map \( X_n \rightarrow Z_n \) is a Cartesian transformation of simplicial objects (Theorem T.6.1.3.9): in other words, it will suffice to show that for every morphism \([m] \rightarrow [n]\) in \( \Delta \), the analogous diagram

\[
\begin{array}{ccc}
X_n & \longrightarrow & X_m \\
\downarrow & & \downarrow \\
Z_n & \longrightarrow & Z_m
\end{array}
\]

is a pullback square. Choosing a map \([0] \rightarrow [m]\), we obtain a larger diagram

\[
\begin{array}{ccc}
X_n & \longrightarrow & X_m & \longrightarrow & X_0 \\
\downarrow & & \downarrow & & \downarrow \\
Z_n & \longrightarrow & Z_m & \longrightarrow & Z_0.
\end{array}
\]

Since \( Z_0 \) is a final object of \( \mathcal{X} \), condition (ii′) implies that the right square and the outer rectangle are pullback diagrams, so that the left square is a pullback diagram as well. A similar argument shows that \( Y_n \rightarrow Z_n \) and \( W_n \rightarrow Z_n \) are Cartesian transformations, so that \( G \) is a right Kan extension of \( G|K' \) at \((1,0,[n])\) and \((0,0,[n])\) for each \( n \geq 0 \).

To complete the proof, we must show that \( G \) is a right Kan extension of \( G|K' \) at \((0,0,[-1])\): in other
words, that the diagram $\sigma$:

\[
\begin{array}{ccc}
W_{-1} & \longrightarrow & X_{-1} \\
\downarrow & & \downarrow \\
Y_{-1} & \longrightarrow & Z_{-1}
\end{array}
\]

is a pullback square. Since the map $\epsilon : Z_0 \to Z_{-1}$ is an effective epimorphism, it suffices to show that the diagram $\sigma$ becomes a pullback square after base change along $\epsilon$. In other words, we need only show that the diagram

\[
\begin{array}{ccc}
W_0 & \longrightarrow & X_0 \\
\downarrow & & \downarrow \\
Y_0 & \longrightarrow & Z_0
\end{array}
\]

is a pullback square, which follows immediately from ($ii'$).

Proof of Theorem 5.5.6.6 for $k \geq 2$. Replacing $E$ by $|\text{Sing}(E)|$, we can assume without loss of generality that $E$ is the geometric realization of a simplicial set $X$ equipped with a Kan fibration $X \to \text{Sing}(M)$. We wish to prove that the canonical map $\int_M E' \to \Gamma_c(M; E)$ is a homotopy equivalence. For this, it suffices to show that $\tau_{\leq m}(\int_M E') \to \tau_{\leq m}\Gamma_c(M; E)$ is a homotopy equivalence for every integer $m \geq 0$. Since the truncation functor $\tau_{\leq m} : \mathcal{S} \to \tau_{\leq m}\mathcal{S}$ preserves small colimits and finite products, Proposition 5.5.2.17 allows us to identify the left hand side with the topological chiral homology $\int_M(\tau_{\leq m}E')$ in the $\infty$-category $\tau_{\leq m}\mathcal{S}$.

Regard $X$ as an object of the $\infty$-topos $\mathcal{X} = \mathcal{S}_{/\text{Sing}(M)}$, let $X'$ be an $(m+k)$-truncation of $X$, and let $E' = |X'|$. The map $X \to X'$ induces a map $E' \to E''$ which is an equivalence on $m$-truncations, and therefore induces an equivalence $\tau_{\leq m}(\int_M E') \to \tau_{\leq m}(\int_M E'')$. This equivalence fits into a commutative diagram

\[
\begin{array}{ccc}
\tau_{\leq m}\int_M E' & \longrightarrow & \tau_{\leq m}\Gamma_c(M; E) \\
\downarrow & & \downarrow \\
\tau_{\leq m}\int_M E'' & \longrightarrow & \tau_{\leq m}\Gamma_c(M; E')
\end{array}
\]

where $\beta$ is also an equivalence (since $M$ has dimension $k$). Consequently, to prove that $\alpha$ is an equivalence, it suffices to prove that $\alpha'$ is an equivalence. We may therefore replace $X$ by $X'$ and thereby reduce to the case where $X$ is an $n$-truncated object of $\mathcal{X}$ for some $n \geq 0$.

The proof now proceeds by induction on $n$. If $n < k$, then $X$ is both $k$-connective and $(k-1)$-truncated, and is therefore equivalent to the final object of $\mathcal{X}$. In this case, both $\int_M E'$ and $\Gamma_c(M; E)$ are contractible and there is nothing to prove. Assume therefore that $n \geq k \geq 2$. Let $A = \pi_n X$, regarded as an object of the topos of discrete sets $\text{Disc } \mathcal{X}/X$. Since $X$ is a 2-connective object of $\mathcal{X}$, this topos is equivalent to the topos of discrete objects $\text{Disc } \mathcal{X}$ of local systems of sets on the manifold $M$. We will abuse notation by identifying $A$ with its image under this equivalence; let $K(A, n+1)$ denote the associated Eilenberg-MacLane objects of $\mathcal{X}$. Let $Y = \tau_{\leq n-1} X$, so that $X$ is an $n$-gerbe over $Y$ banded by $A$ and therefore fits into a pullback square

\[
\begin{array}{ccc}
X & \longrightarrow & 1 \\
\downarrow & & \downarrow \\
Y & \longrightarrow & K(A, n+1)
\end{array}
\]

Let $E_0 = |Y|$ and $E_1 = |K(A, n+1)|$, so that we have a fiber sequence $E \to E_0 \to E_1$ of Serre fibrations
over $M$. We then have a commutative diagram

$$
\begin{array}{ccc}
\int_M E^i & \rightarrow & \int_M E_0^i \\
\downarrow & & \downarrow \\
\Gamma_c(M; E) & \rightarrow & \Gamma_c(M; E_0)
\end{array}
\begin{array}{ccc}
\int_M E_1^i & \rightarrow & \int_M E_1 \\
\downarrow & & \downarrow \\
\Gamma_c(M; E) & \rightarrow & \Gamma_c(M; E_1)
\end{array}
$$

where $\alpha_0$ is a homotopy equivalence by the inductive hypothesis, and $\alpha_1$ is a homotopy equivalence by Proposition 5.5.6.16. Consequently, to prove that $\alpha$ is a homotopy equivalence, it suffices to prove that the upper line is a fiber sequence. The algebras $E^i$, $E_0^i$, and $E_1^i$ determine functors $\chi, \chi_0, \chi_1 : D(M) \rightarrow S_*$, which fit into a pullback square

$$
\begin{array}{ccc}
\chi & \rightarrow & * \\
\downarrow & & \downarrow \\
\chi_0 & \rightarrow & \chi_1.
\end{array}
$$

To complete the proof, it suffices to show that the induced square of colimits

$$
\begin{array}{ccc}
\lim \chi & \rightarrow & * \\
\downarrow & & \downarrow \\
\lim \chi_0 & \rightarrow & \lim \chi_1
\end{array}
$$

is again a pullback diagram. Since $n \geq k$, the object $K(A, n+1)$ is $(k+1)$-connective, so that $\chi_1$ takes values in connected spaces. The desired result now follows from Lemma 5.5.6.17, since $D(M)$ is sifted (Proposition 5.5.2.15).
Chapter 6

The Calculus of Functors

Let $f : \mathbb{R} \to \mathbb{R}$ be a smooth function. Then, for each point $x_0 \in \mathbb{R}$, there exists a real number $s = f'(x_0)$ such that $f$ is closely approximated by the linear function $x \mapsto f(x_0) + s(x - x_0)$ in a small neighborhood of $x_0$. For many purposes, this allows us to reduce questions about arbitrary smooth functions to questions about linear functions, which are usually much more tractable.

In this chapter, we will give an exposition of Goodwillie’s calculus of functors, which attempts to exploit the same idea in a different context: rather than looking for approximations to a smooth function $f : \mathbb{R} \to \mathbb{R}$, we instead seek linear (or polynomial) approximations to a functor of $\infty$-categories $F : \mathcal{C} \to \mathcal{D}$. Our investigation is loosely informed by the following table of analogies:

<table>
<thead>
<tr>
<th>Differential Calculus</th>
<th>Calculus of Functors</th>
</tr>

</tr>
</tbody>
</table>

We will begin in §6.1 by reviewing the contents of Goodwillie’s paper [60], which introduces and analyzes a sequence of Taylor approximations $P_n(F)$ to a functor $F : \mathcal{C} \to \mathcal{D}$ between compactly generated $\infty$-categories. Restricting to the case $n = 1$, we obtain a theory of first derivatives, which we will study in §6.2. One of our main results is the Klein-Rognes chain rule (Theorem 6.2.1.22), which asserts that (under some mild hypotheses) the first derivative of a composite functor $G \circ F$ is obtained by composing the derivative of $G$ with the derivative of $F$. In §6.3, we discuss the chain rule of Arone-Ching, a more general statement which gives information about the higher derivatives of a composite functor. Using the theory of $\infty$-operads developed in §2, we formulate and prove a Koszul dual version of this chain rule.
6.1 The Calculus of Functors

Let \( f : \mathbb{R} \to \mathbb{R} \) be a smooth (that is, infinitely differentiable) function. For each \( n \geq 0 \), Taylor’s formula gives an identity

\[
f(x) = c_0 + c_1 x + \cdots + c_n x^n + u(x)x^{n+1}
\]

where \( c_m = \frac{f^{(m)}(0)}{m!} \) and \( u : \mathbb{R} \to \mathbb{R} \) is another infinitely differentiable function. We will refer to the polynomial \( g(x) = c_0 + c_1 x + \cdots + c_n x^n \) as the \( n \)th Taylor approximation to \( f \) (at the point \( 0 \in \mathbb{R} \)). It is uniquely characterized by the following properties:

(a) The function \( g(x) \) is a polynomial of degree \( \leq n \).

(b) The difference \( f(x) - g(x) \) vanishes to order \( n \) at \( 0 \in \mathbb{R} \).

Our goal in this section is to give an exposition of Goodwillie’s calculus of functions, which develops an analogous theory of Taylor approximations where we replace the real numbers \( \mathbb{R} \) by the \( \infty \)-category \( \text{Sp} \) of spectra, and replace smooth functions \( f : \mathbb{R} \to \mathbb{R} \) by functors \( F : \text{Sp} \to \text{Sp} \) which commute with filtered colimits.

**Question 6.1.0.1.** Let \( F : \text{Sp} \to \text{Sp} \) be a functor which commutes with filtered colimits. Can we find another functor \( G : \text{Sp} \to \text{Sp} \) satisfying some analogues of conditions (a) and (b)?

To address Question 6.1.0.1, we first need to isolate a class of functors \( G : \text{Sp} \to \text{Sp} \) which behave like polynomials of degree \( \leq n \). Note that function \( f : \mathbb{R} \to \mathbb{R} \) is a polynomial of degree \( \leq n \) if and only if it can be written as an \( \mathbb{R} \)-linear combination of the functions \( \{q_m : \mathbb{R} \to \mathbb{R}\}_{0 \leq m \leq n} \) given by \( q_m(x) = x^m \). Each of these functions has an obvious analogue in the setting of functors from \( \text{Sp} \) to \( \text{Sp} \); namely, the functor \( Q_m : \text{Sp} \to \text{Sp} \) given by \( Q_m(X) = X^\otimes m \) determined by the smash product monoidal structure on \( \text{Sp} \) (see §4.8.2). This motivates the following definition:

**Definition 6.1.0.2.** We let \( \text{Poly}^n(\text{Sp}, \text{Sp}) \) denote the smallest full subcategory of \( \text{Fun}(\text{Sp}, \text{Sp}) \) which is closed under translation, small colimits and contains the functors \( Q_m : \text{Sp} \to \text{Sp} \) for \( 0 \leq m \leq n \). We will say that a functor \( G : \text{Sp} \to \text{Sp} \) is polynomial of degree \( \leq n \) if it belongs to \( \text{Poly}^n(\text{Sp}, \text{Sp}) \).

**Example 6.1.0.3.** For every sequence of “coefficients” \( C_0, C_1, \ldots, C_n \in \text{Sp} \), the functor

\[
X \mapsto \bigoplus_{0 \leq m \leq n} C_m \otimes X^\otimes m
\]

from \( \text{Sp} \) to itself is polynomial of degree \( \leq n \). However, not every polynomial functor has this form.

Definition 6.1.0.2 does a good job of capturing the intuitive notion of polynomial for a functor from \( \text{Sp} \) to \( \text{Sp} \). However, for some purposes it is rather inconvenient:

(i) Given a functor \( G : \text{Sp} \to \text{Sp} \), Definition 6.1.0.2 does not immediately suggest any method for testing whether or not \( G \) is a polynomial of degree \( \leq n \).

(ii) Definition 6.1.0.2 relies on specific structural features of the \( \infty \)-category \( \text{Sp} \) (namely, the “monomial” functors \( Q_m : \text{Sp} \to \text{Sp} \)), and does not immediately generalize to other contexts.

For these reasons, it will be convenient to work with a more flexible definition. Suppose that \( \mathcal{E} \) is an \( \infty \)-category which admits finite colimits and that \( \mathcal{D} \) is an \( \infty \)-category which admits finite limits. In §6.1.1, we will introduce the notion of an \( n \)-excisive functor \( F : \mathcal{E} \to \mathcal{D} \) (see Definition 6.1.1.3). This notion is completely intrinsic to \( F \), and is applicable in a wide variety of situations. Moreover, it is closely related to Definition 6.1.0.2: we will eventually show that a functor \( F : \text{Sp} \to \text{Sp} \) is polynomial of degree \( \leq n \) if and only if it is \( n \)-excisive and commutes with filtered colimits (Corollary 6.1.4.15).
6.1. THE CALCULUS OF FUNCTORS

The collection of \( n \)-excisive functors from \( \mathcal{C} \) to \( \mathcal{D} \) span a full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \), which we will denote by \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \). Our first main result is that, under some mild hypotheses (which we will suppress mention of for the moment), the inclusion functor \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \hookrightarrow \text{Fun}(\mathcal{C}, \mathcal{D}) \) admits a left adjoint (Theorem 6.1.1.10). We will denote this left adjoint by \( P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Exc}^n(\mathcal{C}, \mathcal{D}) \). Given an arbitrary functor \( F : \mathcal{C} \to \mathcal{D} \), we can think of \( P_n(F) \) as an \( n \)th Taylor approximation to \( F \): it is, in a precise sense, a “best possible” approximation to \( F \) among \( n \)-excisive functors.

An easy consequence of the definition of \( n \)-excisive functors is that any \( n \)-excisive functor is also \( m \)-excisive for \( m \leq n \) (Corollary 6.1.1.14). From this we deduce the existence of canonical maps \( P_n(F) \to P_m(F) \), which we can arrange into a tower of natural transformations

\[
\cdots \to P_n(F) \to P_{n-1}(F) \to \cdots \to P_0(F),
\]
called the Taylor tower of \( F \).

**Remark 6.1.0.4.** For any functor \( F : \mathcal{C} \to \mathcal{D} \), there is a canonical map \( F \to \varprojlim_{n} P_n(F) \). In many cases, one can show that this natural transformation is an equivalence, or at least an equivalence when restricted to a large subcategory of \( \mathcal{C} \). However, this requires strong assumptions on \( F \): it is analogous to the assertion that an infinitely differentiable function \( f : \mathbb{R} \to \mathbb{R} \) can be recovered from its Taylor series

\[
f(x) = \sum_{n \geq 0} \frac{f^{(n)}(0)}{n!} x^n.
\]

We refer the reader to [59] for a treatment of these types of convergence questions.

In §6.1.2 we will show that the Taylor tower of any functor \( F \) is a tower of principal fibrations. That is, we can always recover \( P_n(F) \) as the homotopy fiber of a map \( P_{n-1}(F) \to R(F) \), where \( R(F) \) is functor which is homogeneous of degree \( n \): that is, \( R(F) \) is \( n \)-excisive and \( P_{n-1}(R(F)) \) is trivial. In this sense, every \( n \)-excisive functor \( F : \mathcal{C} \to \mathcal{D} \) can be “built from” \( m \)-homogeneous functors for \( 0 \leq m \leq n \). This should be regarded as an analogue of the assertion that every polynomial function \( g : \mathbb{R} \to \mathbb{R} \) can be written (uniquely) as a sum of monomials which are homogeneous of degree \( m \) for \( 0 \leq m \leq n \).

In §6.1.4, we will review Goodwillie’s classification of homogeneous functors. The main result is that every \( n \)-homogeneous functor \( H : \mathcal{C} \to \mathcal{D} \) has a unique expression as

\[
H(C) = \Omega^n_D(h(C, C, \ldots, C)_{\Sigma_n}),
\tag{6.1}
\]

where \( h : \mathcal{C}^n \to \text{Sp}(\mathcal{D}) \) is a functor which is \( 1 \)-homogeneous in each variable and symmetric in its arguments, and \( h(C, \ldots, C)_{\Sigma_n} \) denotes the coinvariants for the action of the symmetric group \( \Sigma_n \) on \( h(C, \ldots, C) \) in the \( \infty \)-category \( \text{Sp}(\mathcal{D}) \) (see Theorem 6.1.4.7). In the special case where \( H = \text{fib}(P_n(F) \to P_{n-1}(F)) \) is the \( n \)-homogeneous part of the \( n \)-excisive approximation to \( F \), we can regard the functor \( h \) as an avatar of the \( n \)th derivative of \( F \) (evaluated at zero), so that 6.1 can be regarded as the analogue of the formula \( c_m = \frac{\mathcal{L}^{(m)}}{m!} \) for the coefficients appearing in the Taylor approximation \( g(x) = c_0 + c_1 x + \ldots + c_n x^n \) for a smooth function \( f : \mathbb{R} \to \mathbb{R} \). The proof of Theorem 4.2.1.26 requires an extension of the theory of \( n \)-excisiveness to the setting of functors of many variables, which we describe in §6.1.4.

The remainder of this section is devoted to studying the classification of \( n \)-excisive functors in general. This is quite a bit more difficult than the classification of \( n \)-homogeneous functors: in order to understand an \( n \)-excisive functor \( F \approx P_n(F) \), one must understand not only its homogeneous layers \( \text{fib}(P_n(F) \to P_{n-1}(F)) \) for \( 0 \leq m \leq n \), but also the “\( k \)-invariants” which describe how these layers are connected to one another. In general, this is a difficult problem. However, there are special cases in which one say a great deal. In §6.1.5, we will show that an \( n \)-excisive functor \( F : \mathcal{S} \to \text{Sp} \) which commutes with filtered colimits is determined by its restriction to finite sets of cardinality \( \leq n \), which may be prescribed arbitrarily (Theorem 6.1.5.1). In §6.1.6, we will study the classification of \( n \)-excisive functors between stable \( \infty \)-categories, where the relevant extension problems are controlled by a form of Tate cohomology (see Remark 6.1.6.29).
Remark 6.1.0.5. The calculus of functors was introduced by Tom Goodwillie, and most of the ideas presented in this section are due to him. In particular, our exposition in §6.1.1 through §6.1.4 can be regarded as a translation of Goodwillie’s paper [60] to the language of ∞-categories (in fact, very little translation was necessary: the arguments given in [60] can be adapted to the present setting, without essential change).

6.1.1 n-Excisive Functors

Let ℂ and ℳ be ∞-categories, and assume that ℂ admits finite colimits. Recall that a functor $F : ℂ \to ℳ$ is said to be excisive if it carries pushout squares in ℂ to pullback squares in ℳ (Definition 1.4.2.1). The condition that $F$ be excisive can be regarded as an abstraction of the excision axiom in the definition of a homology theory (see Remark 1.4.3.3). However, there is another way of thinking about excisive functors. If ℂ and ℳ are stable ∞-categories, then a functor $F : ℂ \to ℳ$ is excisive if and only if it is the direct sum of a constant functor and an exact functor (see Remark 1.4.2.2). In the functor-function analogy, such functors correspond to maps between vector spaces which are affine: that is, which can be given by polynomials of degree at most 1. In this section, we will introduce the more general notion of an n-excisive functor $F : ℂ \to ℳ$, which can be viewed as the analogue of inhomogeneous polynomials of degrees ≤ n (Definition 6.1.1.3). The collection of n-excisive functors from ℂ to ℳ span a full subcategory of Fun(ℂ, ℳ), which we will denote by Exc^n(ℂ, ℳ). Our main objective in this section is to show that that, under some mild assumptions on ℂ and ℳ, the inclusion Exc^n(ℂ, ℳ) ⊆ Fun(ℂ, ℳ) admits a left adjoint $P_n : Fun(ℂ, ℳ) \to Exc^n(ℂ, ℳ)$ (Theorem 6.1.1.10).

Notation 6.1.1.1. For every finite set $S$, we let $P(S)$ denote the collection of subsets of $S$. We regard $P(S)$ as a partially ordered set with respect to inclusion. Given an integer $i$, we let $P_{\leq i}(S)$ denote the subset of $P(S)$ consisting of subsets of $S$ having cardinality at most $i$, and $P_{> i}(S)$ the subset of $P(S)$ consisting of those subsets of $S$ having cardinality greater than $i$.

Definition 6.1.1.2. Let ℂ be an ∞-category and $S$ a finite set. An S-cube in ℂ is a functor $N(P(S)) \to ℂ$. We let $Cb_S(ℂ) = Fun(N(P(S)), ℂ)$ denote the ∞-category of S-cubes.

We will say that an S-cube $X : N(P(S)) \to ℂ$ is Cartesian if it is a limit diagram: that is, if $X$ induces an equivalence

$$X(∅) \to \lim_{∅ ≠ S_0 ⊆ S} X(S_0).$$

We will say that an S-cube $X : N(P(S)) \to ℂ$ is strongly coCartesian if $X$ is a left Kan extension of its restriction to $P_{≤ 1}(S)$.

Definition 6.1.1.3. Let ℂ be an ∞-category which admits finite colimits and ℳ an ∞-category which admits finite limits. Let $n ≥ 0$ be an integer and set $S = [n] = \{0, \ldots, n\}$. We will say that a functor $F : ℂ \to ℳ$ is n-excisive if composition with $F$ carries strongly coCartesian S-cubes in ℂ to Cartesian S-cubes in ℳ. We let Exc^n(ℂ, ℳ) denote the full subcategory of Fun(ℂ, ℳ) spanned by the n-excisive functors.

Example 6.1.1.4. Let $S = [0] = \{0\}$. Then an S-cube in an ∞-category ℂ is just a morphism in ℂ. Every S-cube is strongly coCartesian, and an S-cube is Cartesian if and only if the corresponding morphism is an equivalence in ℂ. Consequently, a functor $F : ℂ \to ℳ$ is 0-excisive if and only if it factors through $ℳ^{≥ 0}$: that is, if and only if it carries each morphism in ℂ to an equivalence in ℳ.

Example 6.1.1.5. Let $S = [1] = \{0, 1\}$. Then an S-cube in an ∞-category ℂ is just a commutative diagram

$$C \to C_0 \quad \quad C_1 \to C_{01}.$$

Such a diagram determines a Cartesian S-cube if and only if it is a pullback square, and a coCartesian S-cube if and only if it is a pushout square. Consequently, a functor $F : ℂ \to ℳ$ is 1-excisive if and only if it
6.1. THE CALCULUS OF FUNCTORS

is excisive, in the sense of Definition 1.4.2.1: that is, if and only if it carries pushout squares in \( \mathcal{C} \) to pullback squares in \( \mathcal{D} \).

Our main goal in this section is to construct a left adjoint to the inclusion functor \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \hookrightarrow \text{Fun}(\mathcal{C}, \mathcal{D}) \). For this, we will need to introduce a mild assumption on \( \mathcal{D} \).

**Definition 6.1.1.6.** Let \( \mathcal{C} \) be an \( \infty \)-category. We will say that \( \mathcal{C} \) is differentiable if it satisfies the following conditions:

(a) The \( \infty \)-category \( \mathcal{C} \) admits finite limits.

(b) The \( \infty \)-category \( \mathcal{C} \) admits sequential colimits: that is, every diagram \( N(\mathbb{Z}_{\geq 0}) \to \mathcal{C} \) admits a colimit in \( \mathcal{C} \).

(c) The colimit functor \( \text{lim} : \text{Fun}(N(\mathbb{Z}_{\geq 0}), \mathcal{C}) \to \mathcal{C} \) is left exact. More informally: the formation of sequential colimits in \( \mathcal{C} \) commutes with finite limits.

**Example 6.1.1.7.** Let \( \mathcal{C} \) be a stable \( \infty \)-category. Then \( \mathcal{C} \) automatically satisfies condition \((a)\) of Definition 6.1.1.6. Condition \((b)\) is equivalent to the requirement that \( \mathcal{C} \) admits countable coproducts (see Proposition 1.4.4.1). If this condition is satisfied, then \((c)\) follows automatically.

**Example 6.1.1.8.** Every \( \infty \)-topos is differentiable (see Example T.7.3.4.7).

**Example 6.1.1.9.** Let \( \mathcal{C} \) be a compactly generated \( \infty \)-category, and \( \mathcal{C}_c \) the full subcategory of \( \mathcal{C} \) spanned by the compact objects. Then \( \mathcal{C} \simeq \text{Ind}(\mathcal{C}_c) \) can be identified with a full subcategory of \( \text{Fun}(\mathcal{C}_c^{\text{op}}, S) \) which is closed under filtered colimits. It follows that \( \mathcal{C} \) is a presentable \( \infty \)-category and that filtered colimits in \( \mathcal{C} \) are left exact, so that \( \mathcal{C} \) is differentiable.

We can now state the main result of this section:

**Theorem 6.1.1.10.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, and let \( \mathcal{D} \) be a differentiable \( \infty \)-category. Then:

1. The inclusion \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \hookrightarrow \text{Fun}(\mathcal{C}, \mathcal{D}) \) admits a left adjoint \( P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Exc}^n(\mathcal{C}, \mathcal{D}) \).

2. The functor \( P_n \) is left exact.

**Remark 6.1.1.11** (Rezk). Let \( \mathcal{C} \) be a small \( \infty \)-category which admits finite colimits and has a final object, and let \( X \) be an \( \infty \)-topos. Theorem 6.1.1.10 implies that \( \text{Exc}^n(\mathcal{C}, X) \) is an accessible left-exact localization of the \( \infty \)-category \( \text{Fun}(\mathcal{C}, X) \), and therefore an \( \infty \)-topos (which is usually far from hypercomplete when \( n > 0 \)).

We will give the proof of Theorem 6.1.1.10 at the end of this section. First, we record some basic facts about Cartesian and strongly coCartesian cubes.

**Definition 6.1.1.12.** Let \( S \) be a finite set, and suppose we are given a decomposition \( S = T_\ast \amalg T \amalg T_\ast \). The construction \( T_0 \to T \amalg T \amalg T_0 \) determines an order-preserving map from \( \mathcal{P}(T) \) to \( \mathcal{P}(S) \). Given an \( S \)-cube \( X : N(\mathcal{P}(S)) \to \mathcal{C} \) in an \( \infty \)-category \( \mathcal{C} \), the composition \( N(\mathcal{P}(T)) \to N(\mathcal{P}(S)) \to \mathcal{C} \) is a \( T \)-cube in \( \mathcal{C} \). We will refer to the \( T \)-cubes which arise in this way as \( T \)-faces of \( X \).

**Proposition 6.1.1.13.** Let \( S \) be a finite set and \( T \) a finite subset of \( S \). Suppose we are given an \( S \)-cube \( X : N(\mathcal{P}(S)) \to \mathcal{C} \) in an \( \infty \)-category \( \mathcal{C} \). Then:

1. If \( X \) is strongly coCartesian, then every \( T \)-face of \( X \) is strongly coCartesian.

2. If every \( T \)-face of \( X \) is Cartesian, then \( X \) is Cartesian.
Proof. We first prove (1). Assume that $X$ is strongly coCartesian, choose a decomposition $S = T_− \amalg T_1 \amalg T_+$, and let $Y : N(P(T)) \to \mathcal{C}$ be the corresponding $T$-face of $X$. We wish to prove that $Y$ is a left Kan extension of its restriction to $\mathbf{P}_{\leq 1}(T)$. Unwinding the definitions, we must show that for every subset $T_0 \subseteq T$, the functor $X$ induces an equivalence

$$\lim_{T_0'} \lim_{T_0} X(T_- \coprod T_0) \to X(T_- \coprod T_0'),$$

where $T_0'$ ranges over all subsets of $T_0$ having cardinality at most 1. Let $\mathcal{J}$ denote the collection of all subsets $J \subseteq T_- \coprod T_0$ whose intersection with $T_0$ has cardinality at most 1. The construction $T_0' \mapsto T_- \coprod T_0'$ induces an injection $\mathbf{P}_{\leq 1}(T_0) \to \mathcal{J}$. This map admits a left adjoint and therefore induces a left cofinal map of simplicial sets $N(\mathbf{P}_{\leq 1}(T_0)) \to N(\mathcal{J})$. It will therefore suffice to show that $X$ exhibits $X(T_- \coprod T_0)$ as a colimit of the diagram $X|N(\mathcal{J})$. Note that $X|N(\mathcal{J})$ is a left Kan extension of $X|N(\mathbf{P}_{\leq 1}(T_- \coprod T_0))$. It will therefore suffice to show that $X(T_- \coprod T_0)$ is a colimit of the restriction $X|N(\mathbf{P}_{\leq 1}(T_- \coprod T_0))$, which follows from our assumption that $X$ is strongly coCartesian.

We now prove (2). Assume that every $T$-face of $X$ is Cartesian; we will show that $X$ is Cartesian. We wish to show that $X$ exhibits $X(\emptyset)$ as a limit of $X|N(\mathbf{P}_{> 0}(S))$. Let $\mathcal{J}$ denote the subset of $\mathbf{P}(S)$ consisting of those subsets $s_0 \subseteq S$ which have nonempty intersection with $T$. Since the $T$-faces of $X$ are Cartesian, $X|N(\mathbf{P}_{> 0}(S))$ is a right Kan extension of $X|N(\mathcal{J})$. It will therefore suffice to show that $X$ exhibits $X(\emptyset)$ as a limit of the diagram $X|N(\mathcal{J})$. Note that the inclusion $\mathbf{P}_{> 0}(T) \to \mathcal{J}$ admits a right adjoint, so that the map of $\infty$-categories $N(\mathbf{P}_{> 0}(T)) \to N(\mathcal{J})$ is right cofinal. It will therefore suffice to show that $X$ exhibits $X(\emptyset)$ as a limit of the diagram $X|N(\mathbf{P}_{> 0}(T))$, which follows from our assumption that the $T$-faces of $X$ are Cartesian. \hfill $\square$

Corollary 6.1.1.14. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between $\infty$-categories. Assume that $\mathcal{C}$ admits finite colimits and $\mathcal{D}$ admits finite limits. If $F$ is $m$-excisive, the $F$ is $m$-excisive for each $m \geq n$.

Proposition 6.1.1.15. Let $S$ be a finite set, let $\mathcal{C}$ be an $\infty$-category which admits finite colimits, and let $X : N(\mathbf{P}(S)) \to \mathcal{C}$ be an $S$-cube. The following conditions are equivalent:

1. The $S$-cube $X$ is strongly coCartesian.

2. For every pair of finite sets $T, T' \subseteq S$, the diagram

$$\begin{array}{ccc}
X(T \cap T') & \longrightarrow & X(T) \\
\downarrow & & \downarrow \\
X(T') & \longrightarrow & X(T \cup T')
\end{array}$$

is a pushout square in $\mathcal{C}$.

3. For every subset $T \subseteq S$ and every element $s \in S - T$, the diagram

$$\begin{array}{ccc}
X(\emptyset) & \longrightarrow & X(T) \\
\downarrow & & \downarrow \\
X\{\{s\}\} & \longrightarrow & X(T \cup \{s\})
\end{array}$$

is a pushout square in $\mathcal{C}$.

Proof. We first show that (1) $\Rightarrow$ (2). Let $P \subseteq \mathbf{P}(S)$ denote the collection of those subsets $S'$ such that $S' \subseteq T$ or $S' \subseteq T'$, let $P_0 = P \cap \mathbf{P}_{\leq 1}(S)$, and let $P_1 = \{T, T', T \cap T'\}$. We wish to prove that $X$ exhibits $X(T \cup T')$ as a colimit of $X|N(P_1)$. It follows from Theorem T.4.1.3.1 that the inclusion $N(P_1) \subseteq N(P_0)$
is left cofinal. It will therefore suffice to show that \( X \) exhibits \( X(T \cup T') \) as a colimit of \( X|N(P) \). Our assumption that \( X \) is strongly coCartesian implies that \( X|N(P) \) is a left Kan extension of \( X|N(P_0) \). It will therefore suffice to show that \( X \) exhibits \( X(T \cup T') \) as a colimit of \( X|N(P_0) \), which follows immediately from our assumption that \( X \) is strongly coCartesian.

The implication (2) \( \Rightarrow \) (3) is obvious. We will complete the proof by showing that (3) \( \Rightarrow \) (1). Let \( X_0 = X|N(P \leq_1(S)) \). Since \( \mathcal{C} \) admits finite colimits, we can extend \( X_0 \) to a strongly coCartesian \( S \)-cube \( X' : N(P(S)) \to \mathcal{C} \). The identification \( X'|N(P \leq_1(S)) = X|N(P \leq_1(S)) \) extends to a natural transformation \( \alpha : X' \to X \). To prove that \( X \) is strongly coCartesian, it will suffice to show that \( \alpha \) is an equivalence. For each \( T \subseteq S \), let \( \alpha_T : X'(T) \to X(T) \) denote the induced map. We will prove that each of the maps \( \alpha_T \) is an equivalence. We proceed by induction on the cardinality of \( T \). The result is obvious if the cardinality of \( T \) is \( \leq 1 \). Otherwise, choose an element \( s \in T \) and let \( T' = T - \{s\} \). Since \( X' \) and \( X \) both satisfy condition (3), we have a pushout diagram

\[
\begin{array}{ccc}
\alpha_{T'} & \longrightarrow & \alpha_T \\
\downarrow & & \downarrow \\
\alpha_{\{s\}} & \longrightarrow & \alpha_T
\end{array}
\]

in \( \text{Fun}(\Delta^1, \mathcal{C}) \). Since \( \alpha_{T'}, \alpha_T, \) and \( \alpha_{\{s\}} \) are equivalences by the inductive hypothesis, we conclude that \( \alpha_T \) is an equivalence.

**Corollary 6.1.1.16.** Let \( \mathcal{C} \) be a stable \( \infty \)-category, let \( S \) be a finite set, and let \( X : N(P(S)) \to \mathcal{C} \) be an \( S \)-cube in \( \mathcal{C} \). Define \( X' : N(P(S)) \to \mathcal{C}^{\text{op}} \) by the formula \( X'(T) = X(S - T) \). Then:

1. The functor \( X \) is a strongly coCartesian \( S \)-cube in \( \mathcal{C} \) if and only if \( X' \) is a strongly coCartesian \( S \)-cube in \( \mathcal{C}^{\text{op}} \).
2. The functor \( X \) is a Cartesian \( S \)-cube in \( \mathcal{C} \) if and only if \( X' \) is a Cartesian \( S \)-cube in \( \mathcal{C}^{\text{op}} \).

**Proof.** Assertion (2) follows immediately from Proposition 1.2.4.13. Assertion (1) follows from Proposition 1.2.4.13 and the characterization of strongly coCartesian \( S \)-cubes given in Proposition 6.1.1.15.

**Corollary 6.1.1.17.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be stable \( \infty \)-categories, and let \( n \geq 0 \) be an integer. Then a functor \( F : \mathcal{C} \to \mathcal{D} \) is \( n \)-excisive if and only if the induced map \( \mathcal{C}^{\text{op}} \to \mathcal{D}^{\text{op}} \) is \( n \)-excisive.

We now turn to the construction of the functor \( P_n \) appearing in the statement of Theorem 6.1.1.10. First, we need to introduce some notation.

**Construction 6.1.1.18.** Let \( \text{Fin}^{\text{inj}} \) denote the category whose objects are finite sets and whose morphisms are injections, and let \( \text{Fin}_{\leq n}^{\text{inj}} \) denote the full subcategory of \( \text{Fin}^{\text{inj}} \) spanned by those finite sets having cardinality \( \leq n \). Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object. Consider the following conditions on a functor \( F : N(\text{Fin}^{\text{inj}}) \to \mathcal{C} \):

(i) Whenever \( S \) is a set of cardinality exactly 1, the object \( F(S) \in \mathcal{C} \) is final.

(ii) For every finite set \( S \), \( F \) exhibits \( F(S) \) as the colimit of the diagram \( F|N(P \leq_1(S)) \).

Let \( \mathcal{C} \) denote the full subcategory of \( \text{Fun}(N(\text{Fin}^{\text{inj}}), \mathcal{C}) \) spanned by those functors which satisfy (i) and (ii). Condition (i) is equivalent to the requirement that \( F|N(\text{Fin}_{\leq 0}^{\text{inj}}) \) is a right Kan extension of \( F|N(\text{Fin}_{\leq 0}^{\text{inj}}) \), and condition (ii) is equivalent to the requirement that \( F \) is a left Kan extension of \( F|N(\text{Fin}_{\leq 1}^{\text{inj}}) \). Using Proposition T.4.3.2.15, we deduce that the evaluation functor \( \mathcal{C} \to \mathcal{C} \) determines a trivial Kan fibration \( \mathcal{C} \to \mathcal{C} \). Choose a section of this Kan fibration. We can regard this section as determining a functor \( \mathcal{C} \times N(\text{Fin}^{\text{inj}}) \to \mathcal{C} \), which we will denote by \( (X, S) \mapsto C_S(X) \). We will refer to \( C_S(X) \) as the \( S \)-pointed cone on \( X \).
**Example 6.1.1.19.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object $\ast$. If $S = \emptyset$, we have $C_S(X) = X$ for each $X \in \mathcal{C}$. If $S$ has a single element, then $C_S(X)$ is a final object of $\mathcal{C}$. If $S$ has two elements, then we can identify $C_S : \mathcal{C} \to \mathcal{C}$ with the (unreduced) suspension functor $\Sigma_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$, which carries an object $X \in \mathcal{C}$ to a pushout $\ast \amalg_X \ast$.

**Remark 6.1.1.20.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories which admit finite colimits and final objects, and let

$$
C^\mathcal{C} : \mathcal{C} \times N(\mathcal{F}\text{in}^{\text{inj}}) \to \mathcal{C} \quad C^\mathcal{D} : \mathcal{D} \times N(\mathcal{F}\text{in}^{\text{inj}}) \to \mathcal{D}
$$

be as in Construction 6.1.1.18. Suppose $F : \mathcal{C} \to \mathcal{D}$ is a functor which preserves final objects and pushouts. Then composition with $F$ carries $\mathcal{C}$ into $\mathcal{D}$ (where $\mathcal{C}$ and $\mathcal{D}$ are defined as in Construction 6.1.1.18). It follows that the diagram

$$
\begin{array}{ccc}
\mathcal{C} \times N(\mathcal{F}\text{in}^{\text{inj}}) & \xrightarrow{F \times \text{id}} & \mathcal{D} \times N(\mathcal{F}\text{in}^{\text{inj}}) \\
\downarrow^{C^\mathcal{C}} & & \downarrow^{C^\mathcal{D}} \\
\mathcal{C} & \xrightarrow{F} & \mathcal{D}
\end{array}
$$

commutes up to canonical homotopy.

**Example 6.1.1.21.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object. For every finite set $S$, the functor $X \mapsto C_S(X)$ preserves final objects and finite colimits. Using Remark 6.1.1.20, we conclude that for every pair of finite sets $S$ and $T$, we have a canonical equivalence of functors $C_S \circ C_T \simeq C_T \circ C_S$. This equivalence depends functorially on the pair $(S,T)$.

**Construction 6.1.1.22.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ an $\infty$-category which admits finite limits, and let $F : \mathcal{C} \to \mathcal{D}$ a functor. For each integer $n \geq 0$, we define a new functor $T_n(F) : \mathcal{C} \to \mathcal{D}$ by the formula

$$(T_n F)(X) = \lim_{\emptyset \neq S \subseteq [n]} F(C_S(X)).$$

The canonical map

$$F(X) = F(C_{\emptyset}(X)) \to \lim_{\emptyset \neq S \subseteq [n]} F(C_S(X))$$

determines a natural transformation of functors $F \to T_n F$, which depends functorially on $F$.

**Example 6.1.1.23.** Let $F : \mathcal{C} \to \mathcal{D}$ be as in Construction 6.1.1.22, and let $\ast$ denote a final object of $\mathcal{C}$. Then $T_0 F$ is equivalent to the constant functor taking the value $F(\ast)$. If $F$ is reduced (that is, $F(\ast)$ is a final object of $\mathcal{D}$), then $T_1(F)$ is given by the composition $\Omega_{\mathcal{D}} \circ F \circ \Sigma_{\mathcal{C}}$.

**Remark 6.1.1.24.** The construction $F \mapsto T_n F$ commutes with finite limits (in fact, it commutes with $K$-indexed limits, for any simplicial set $K$ such that $\mathcal{D}$ admits $K$-indexed limits).

**Remark 6.1.1.25.** In the situation of Construction 6.1.1.22, suppose we are given another $\infty$-category $\mathcal{C}$ which admits finite colimits and a final object, and a functor $F' : \mathcal{C}' \to \mathcal{C}$ which preserves pushouts and final objects. Then we have a canonical equivalence of functors $T_n(F \circ F') \simeq (T_n F) \circ F'$.

**Lemma 6.1.1.26.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and a final object, let $\mathcal{D}$ be an $\infty$-category which admits finite limits, and let $F : \mathcal{C} \to \mathcal{D}$ be a functor. Let $n \geq 0$ and let $S = [n] = \{0, \ldots, n\}$. Suppose that $X : N(\mathcal{P}(S)) \to \mathcal{C}$ is a strongly coCartesian $S$-cube. Then the canonical map of $S$-cubes $\theta_F : F(X) \to (T_n F)(X)$ factors through a Cartesian $S$-cube of $\mathcal{D}$.

**Proof (Rezk):** Let $\theta : \mathcal{C} \to \text{Cb}_{S}(\mathcal{C})$ be given by the formula $\theta(U)(I) = C_I(U)$. For every subset $I \subseteq S$, let $X_I : N(\mathcal{P}(S)) \to \mathcal{C}$ denote the functor given by the formula $X_I(I') = X(I \cup I')$. Note that each $X_I$ is a left Kan extension of its restriction to $N(\mathcal{P}_{<1}(S))$. Since $\theta(X(I)) \mid_N N(\mathcal{P}_{<1}(S))$ is a right Kan extension of its
restriction to \(N(\mathcal{P}_{\leq 0}(\mathcal{S}))\), the identity map \(X_I(\emptyset) \to \theta(X(I))(\emptyset)\) admits an essentially unique extension to a map of \(S\)-cubes \(X_I \to \theta(X(I))\), depending functorially on \(I\). Define
\[
Y(I) = \lim_{\emptyset \neq S' \subseteq S} F(X_I(S')).
\]
The map \(\theta : F(X) \to (T_n F)(X)\) factors canonically as a composition
\[
F(X) \to Y \to (T_n F)(X).
\]
To complete the proof, it will suffice to show that \(Y\) is a Cartesian \(S\)-cube. Since the collection of Cartesian \(S\)-cubes is stable under finite limits, it will suffice to show that for every nonempty set \(S' \in S\), the functor \(T \mapsto F(X_I(S')) = F(X(I \cup S'))\) is a Cartesian \(S\)-cube. Since every \(S'\)-face of this \(S\)-cube is constant and \(S'\) is nonempty, every \(S'\)-face is Cartesian; the desired result now follows from Proposition 6.1.1.13.

**Construction 6.1.1.27.** Let \(\mathcal{C}\) be an \(\infty\)-category which admits finite colimits and has a final object. Suppose we are given a functor \(F : \mathcal{C} \to \mathcal{D}\), where \(\mathcal{D}\) is differentiable. For each integer \(n \geq 0\), we let \(P_n F\) denote the colimit of the sequence of functors
\[
F \xrightarrow{\theta_{F^n}} T_n F \xrightarrow{\theta_{T_n F^n}} T_n T_n F \to \cdots
\]
We will refer to \(P_n F\) as the \(n\)-excisive approximation to \(F\).

**Example 6.1.1.28.** Let \(F : \mathcal{C} \to \mathcal{D}\) be as in Construction 6.1.1.27. If \(F\) is reduced, then the 1-excisive approximation to \(F\) is given by \(\lim_{\longrightarrow m} \Omega_{\mathcal{D}}^m \circ F \circ \Sigma_{\mathcal{C}}^m\) (see Example 6.1.1.23).

**Remark 6.1.1.29.** In the situation of Construction 6.1.1.27, the construction \(F \mapsto P_n F\) commutes with finite limits. This follows from Remark 6.1.1.24, since the formation of finite limits in \(\mathcal{D}\) commutes with sequential colimits.

**Remark 6.1.1.30.** In the situation of Construction 6.1.1.27, suppose we are given another \(\infty\)-category \(\mathcal{C}'\) which admits finite colimits and a final object, and let \(F' : \mathcal{C}' \to \mathcal{D}\) be a functor which preserves pushouts and final objects. Then we have a canonical equivalence of functors \(P_n(F \circ F') \simeq (P_n F) \circ F'\).

**Remark 6.1.1.31.** In the situation of Construction 6.1.1.27, let \(K\) be a simplicial set such that \(\mathcal{D}\) admits \(K\)-indexed colimits, and the formation of \(K\)-indexed colimits commutes with the formation of finite limits. It follows that the construction \(F \mapsto T_n F\) commutes with \(K\)-indexed colimits, so that the construction \(F \mapsto P_n F\) commutes with \(K\)-indexed colimits. In particular, the hypotheses of Construction 6.1.1.27 guarantee that the construction \(F \mapsto P_n F\) commutes with sequential colimits.

**Remark 6.1.1.32.** In the situation of Construction 6.1.1.27, suppose we are given another differentiable \(\infty\)-category \(\mathcal{D}'\) and let \(G : \mathcal{D} \to \mathcal{D}'\) be a functor which preserves finite limits and sequential colimits. For any functor \(F : \mathcal{C} \to \mathcal{D}\), we have a canonical equivalence \(P_n(G \circ F) \simeq G \circ P_n(F)\).

We now wish to show that the functor \(F \mapsto P_n F\) satisfies the conclusions of Theorem 6.1.1.10.

**Lemma 6.1.1.33.** Let \(\mathcal{C}\) be an \(\infty\)-category which admits finite colimits and has a final object. Suppose we are given a functor \(F : \mathcal{C} \to \mathcal{D}\), where \(\mathcal{D}\) is differentiable. Then the functor \(P_n F : \mathcal{C} \to \mathcal{D}\) is \(n\)-excisive.

**Proof.** Let \(S = [n] = \{0, \ldots, n\}\), and let \(X : N(\mathcal{P}(S)) \to \mathcal{C}\) be a strongly coCartesian \(S\)-cube; we wish to show that \((P_n F)(X)\) is a Cartesian \(S\)-cube in \(\mathcal{D}\). We can write \((P_n F)(X)\) as the colimit of a sequence of \(S\)-cubes
\[
F(X) \to (T_n F)(X) \to (T_n^2 F)(X) \to \cdots
\]
According to Lemma 6.1.1.26, each of the maps \((T_n^k F)(X) \to (T_n^{k+1} F)(X)\) factors through a Cartesian \(S\)-cube \(Y_k\) in \(\mathcal{D}\). Then \((P_n F)(X)\) can be realized as the colimit of the sequence of \(S\)-cubes
\[
Y_0 \to Y_1 \to Y_2 \to \cdots
\]
Since each \(Y_i\) is Cartesian and finite limits in \(\mathcal{D}\) commute with sequential colimits, we conclude that \((P_n F)(X) \simeq \lim_i Y_i\) is Cartesian, as desired.

\[\square\]
Lemma 6.1.1.34. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object. Suppose we are given a functor \( F : \mathcal{C} \to \mathcal{D} \), where \( \mathcal{D} \) is a differentiable \( \infty \)-category. Let \( \theta \) denote the canonical map from \( F \) to \( T_n F \). Then \( \theta \) induces an equivalence \( P_n(F) \to P_n(T_n F) \).

Proof. We have \( T_n F = \lim_{\psi \not\in S \subseteq [n]} F \circ C_S \). Since \( P_n \) commutes with finite limits (Remark 6.1.1.29), the canonical map \( P_n(T_n F) \to \lim_{\psi \not\in S \subseteq [n]} P_n(F \circ C_S) \) is an equivalence. Each of the functors \( C_S \) preserves pushouts and final objects, so that Remark 6.1.1.30 gives an equivalence \( P_n(T_n F) \simeq \lim_{\psi \not\in S \subseteq [n]} (P_n F) \circ C_S \).

It will therefore suffice to show that the canonical map \( P_n F \to \lim_{\psi \not\in S \subseteq [n]} (P_n F) \circ C_S \) is an equivalence, which follows immediately from Lemma 6.1.1.33.

Lemma 6.1.1.35. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor, where \( \mathcal{C} \) admits finite colimits and has a final object and \( \mathcal{D} \) is differentiable. Let \( \phi : F \to P_n F \) be the canonical natural transformation. Then \( P_n(\phi) : P_n(F) \to P_n(P_n(F)) \) is an equivalence.

Proof. Using Remark 6.1.1.31, we can identify \( P_n(\phi) \) with the colimit of the sequence of natural transformations \( P_n(F) \to P_n(T_n^k(F)) \), each of which factors as a composition of equivalences

\[
P_n(F) \to P_n(T_n(F)) \to P_n(T_n^2(F)) \to \cdots \to P_n(T_n^k(F))
\]

by virtue of Lemma 6.1.1.34.

Proof of Theorem 6.1.1.10. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, let \( \mathcal{D} \) be a differentiable \( \infty \)-category, and let \( P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D}) \) be the functor given by Construction 6.1.1.27. We have already seen that \( P_n \) is left exact (Remark 6.1.1.29), and the essential image of \( P_n \) is contained in \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \) (Lemma 6.1.1.33). If \( F \in \text{Fun}(\mathcal{C}, \mathcal{D}) \) is \( n \)-excisive, then it follows immediately from the definition that the canonical map \( F \to T_n F \) is an equivalence. Applying this observation iteratively, we deduce that the canonical map \( F \to P_n F \) is an equivalence, so that \( F \) belongs to the essential image of the functor \( P_n \).

By construction, we have a natural transformation \( \theta : \text{id} \to P_n \) of functors from \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) to itself. We will complete the proof by showing that \( \theta \) exhibits \( P_n \) as a localization functor. According to Proposition 5.2.7.4, it will suffice to show that for every \( F \in \text{Fun}(\mathcal{C}, \mathcal{D}) \), the canonical maps

\[
P_n(\theta F), \theta P_n F : P_n(F) \to P_n(P_n(F))
\]

are equivalences. The map \( \theta P_n(F) \) is an equivalence by the argument given above, since \( P_n(F) \) is \( n \)-excisive by Lemma 6.1.1.33. We conclude by applying Lemma 6.1.1.35 to deduce that \( P_n(\theta F) \) is also an equivalence.

6.1.2 The Taylor Tower

Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, and let \( \mathcal{D} \) be a differentiable \( \infty \)-category. For every integer \( n \geq 0 \), we let \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) spanned by the \( n \)-excisive functors (Definition 6.1.1.3), and \( P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Exc}^n(\mathcal{C}, \mathcal{D}) \) a left adjoint to the inclusion functor (see Theorem 6.1.1.10). According to Corollary 6.1.1.14, we have inclusions

\[
\cdots \subseteq \text{Exc}^3(\mathcal{C}, \mathcal{D}) \subseteq \text{Exc}^2(\mathcal{C}, \mathcal{D}) \subseteq \text{Exc}^1(\mathcal{C}, \mathcal{D}) \subseteq \text{Exc}^0(\mathcal{C}, \mathcal{D}),
\]

so that the localization functors \( P_n \) form an inverse system

\[
\cdots \to P_3 \to P_2 \to P_1 \to P_0.
\]

If \( F : \mathcal{C} \to \mathcal{D} \) is a functor, then we obtain a diagram of functors

\[
\cdots \to P_3 F \to P_2 F \to P_1 F \to P_0 F
\]
6.1. THE CALCULUS OF FUNCTORS

is called the Taylor tower of $F$. We can think of the Taylor tower $\{P_nF\}_{n \geq 0}$ as a sequence of approximations to the functor $F$, which become more accurate as $n$ grows large. Our goal in this section is to study the difference between successive Taylor approximations (as measured, for example, by taking fibers of the maps $P_nF \to P_{n-1}F$). Before we can state our main result, we need to introduce a bit of terminology.

**Definition 6.1.2.1.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, and let $\mathcal{D}$ be a differentiable $\infty$-category. If $n$ is a positive integer, we say that a functor $F : \mathcal{C} \to \mathcal{D}$ is $n$-reduced if $P_{n-1}F$ is a final object of $\operatorname{Exc}^{n-1}(\mathcal{C}, \mathcal{D})$ (that is, if $(P_{n-1}F)(C)$ is a final object of $\mathcal{D}$, for each $C \in \mathcal{C}$).

We will say that $F$ is $n$-homogeneous if it is $n$-excisive and $n$-reduced. We let $\operatorname{Exc}_n^\ast(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\operatorname{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which are $n$-excisive and $1$-reduced, and $\operatorname{Homog}^n(\mathcal{C}, \mathcal{D})$ the full subcategory of $\operatorname{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which are $n$-homogeneous.

**Remark 6.1.2.2.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor, where $\mathcal{C}$ has finite colimits and a final object and $\mathcal{D}$ is differentiable. Then $P_0F$ can be identified with the constant functor taking the value $F(\ast)$, where $\ast$ denotes a final object of $\mathcal{C}$. Consequently, the functor $F$ is $1$-reduced if and only if $F(\ast)$ is a final object of $\mathcal{D}$: that is, if and only if $F$ is reduced, in the sense of Definition 1.4.2.1.

**Remark 6.1.2.3.** In the situation of Definition 6.1.2.1, the functors $P_n$ and $P_{n-1}$ commute with sequential colimits (Remark 6.1.1.31). It follows that the collections of $n$-excisive and $n$-reduced functors are closed under sequential colimits in $\operatorname{Fun}(\mathcal{C}, \mathcal{D})$. In particular, the full subcategory $\operatorname{Homog}^n(\mathcal{C}, \mathcal{D}) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{D})$ is closed under sequential colimits.

We can now state the main result of this section.

**Theorem 6.1.2.4 (Goodwillie).** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ be a differentiable $\infty$-category, and let $n \geq 1$ be an integer. Then there exists a pullback diagram of functors

$$
\begin{array}{ccc}
P_n & \to & P_{n-1} \\
\downarrow & & \downarrow \\
K & \to & R
\end{array}
$$

from $\operatorname{Fun}_*^{\ast}(\mathcal{C}, \mathcal{D})$ to itself having the following properties:

1. For every reduced functor $F : \mathcal{C} \to \mathcal{D}$, $K(F)$ carries every object of $\mathcal{C}$ to a final object of $\mathcal{D}$.

2. For every reduced functor $F : \mathcal{C} \to \mathcal{D}$, the functor $R(F)$ is $n$-homogeneous.

3. The functor $R : \operatorname{Fun}_*^{\ast}(\mathcal{C}, \mathcal{D}) \to \operatorname{Fun}_*^{\ast}(\mathcal{C}, \mathcal{D})$ is left exact.

4. If $F \in \operatorname{Fun}_*^{\ast}(\mathcal{C}, \mathcal{D})$ is $(n-1)$-excisive, then $R(F)$ carries each object of $\mathcal{C}$ to a final object of $\mathcal{D}$.

Before proving Theorem 6.1.2.4, let us describe some of its consequences.

**Theorem 6.1.2.5.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ be a differentiable $\infty$-category, and let $n \geq 1$ be an integer. Let $\mathcal{E} \subseteq \operatorname{Fun}(\Lambda^2_n, \operatorname{Fun}_*^{\ast}(\mathcal{C}, \mathcal{D}))$ spanned by those diagrams of functors

$$
E \to H \leftarrow H_0
$$

where $E$ is reduced and $(n-1)$-excisive, $H$ is $n$-homogeneous, and $H_0$ is a final object of $\operatorname{Fun}(\mathcal{C}, \mathcal{D})$. Then the construction

$$
\lim_{\leftarrow} : \operatorname{Fun}(\Lambda^2_n, \operatorname{Fun}_*^{\ast}(\mathcal{C}, \mathcal{D})) \to \operatorname{Fun}_*^{\ast}(\mathcal{C}, \mathcal{D})
$$

induces an equivalence of $\infty$-categories $\mathcal{E} \to \operatorname{Exc}_n^\ast(\mathcal{C}, \mathcal{D})$. 

In other words, every reduced \( n \)-excisive functor \( F : \mathcal{C} \to \mathcal{D} \) can be written uniquely as a fiber of some natural transformation \( \alpha : E \to H \), where \( E \) is a reduced \( (n - 1) \)-excisive functor and \( H \) is \( n \)-homogeneous functor. Here the fiber is taken over a “base point” given by a natural transformation \( \beta : H_0 \to H \), where \( H_0 \) is a final object of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \). We can identify \( \beta \) with a lifting of \( H \) to an \( n \)-homogeneous functor from \( \mathcal{C} \) to the \( \infty \)-category \( \mathcal{D}^\ast \) of pointed objects of \( \mathcal{D} \). The \textit{existence} of the natural transformation \( \alpha \) follows immediately from Theorem 6.1.2.4 (namely, we take \( \alpha \) to be the natural transformation \( P_{n-1}(F) \to R(F) \) appearing in the statement of Theorem 6.1.2.4). We will deduce the uniqueness from the following somewhat technical lemma:

**Lemma 6.1.2.6.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite limits. Suppose we are given a diagram \( \sigma : \)

\[
\begin{array}{ccc}
X_{00} & \longrightarrow & X_{01} & \phi' \\
\downarrow & & \downarrow \phi & \\
X_{10} & \longrightarrow & X_{11} & \psi \\
\uparrow \psi' & & \uparrow & \\
X_{20} & \longrightarrow & X_{21} & \phi \\
\end{array}
\]

For \( i \in \{0, 1, 2\} \), let \( X^h_i \) denote the fiber product \( X_{i0} \times X_{i1}, X_{i2} \), and let \( X^v_i \) denote the fiber product \( X_{0i} \times X_{1i}, X_{2i} \). Assume that \( \phi, \phi', \psi, \) and \( \psi' \) are equivalences. Then the diagrams \( \Lambda^2_2 \to \mathcal{C} \) given by

\[
X^h_0 \to X^h_1 \leftarrow X^h_2
\]

and

\[
X^v_0 \to X^v_1 \leftarrow X^v_2
\]

are equivalent. Moreover, the equivalence can be chosen to depend functorially on \( \sigma \).

**Proof.** Let \( \sigma_- \) denote the diagram obtained from \( \sigma \) by omitting the lower right corner, \( \sigma_+ \) the diagram obtained from \( \sigma \) by omitting the upper left corner, and \( \sigma_0 \) the diagram obtained from \( \sigma \) by omitting both the upper left and lower right corners. We will prove that the diagram

\[
X^h_0 \to X^h_1 \leftarrow X^h_2
\]

is canonically equivalent to the diagram

\[
\lim \sigma_- \to \lim \sigma_0 \leftarrow \lim \sigma_+
\]

(via an equivalence which depends functorially in \( \sigma \)) By symmetry, it will follow that

\[
X^v_0 \to X^v_1 \leftarrow X^v_2
\]

is also equivalent to (6.2), and the proof will be complete.

Let \( \sigma'_- \) denote the diagram obtained from \( \sigma \) by omitting the lower row, \( \sigma'_+ \) the diagram obtained from \( \sigma \) by omitting the upper row, and \( \sigma'_0 \) the diagram obtained from \( \sigma \) by omitting both the upper and lower rows. Then

\[
X^h_0 \to X^h_1 \leftarrow X^h_2
\]

can be identified with the upper row of the commutative diagram

\[
\begin{array}{ccc}
\lim \sigma'_- & \longrightarrow & \lim \sigma'_0 & \longrightarrow & \lim \sigma'_+ \\
\uparrow & & \theta & & \uparrow \\
\lim \sigma_- & \longrightarrow & \lim \sigma_0 & \longrightarrow & \lim \sigma_+.
\end{array}
\]
It will therefore suffice to show that the vertical maps in this diagram are equivalences. We will show that the map $\theta$ is an equivalence; the proofs for the other two maps are similar (but easier). Consider the diagram $\sigma''_0$:

\[
\begin{array}{cccc}
X_{02} & \xrightarrow{\phi} & X_{10} & \downarrow \psi \\
& & X_{11} & \leftarrow X_{12} \\
X_{20} & \uparrow \phi & \rightarrow & \\
\end{array}
\]

The map $\theta$ factors as a composition $\lim \leftarrow \sigma_0 \theta' \rightarrow \lim \leftarrow \sigma''_0 \theta'' \rightarrow \lim \leftarrow \sigma'$. Since $\phi$ and $\psi$ are equivalences, the diagram $\sigma''_0$ is a right Kan extension of $\sigma'_0$, so that $\theta''$ is an equivalence. The map $\theta'$ is an equivalence by a cofinality argument, so that $\theta$ is an equivalence as desired.

Proof of Theorem 6.1.2.5. Since the collection of reduced, $n$-excisive functors is closed under limits, it is clear that the formation of fiber products induces a functor $\phi : E \rightarrow \text{Exc}^*_n(C, D)$. The construction which carries a functor $F$ to the diagram $P_{n-1}(F) \rightarrow R(F) \leftarrow K(F)$ (see Theorem 6.1.2.4) determines a functor $\psi : \text{Exc}^*_n(C, D) \rightarrow E$. It follows from Theorem 6.1.2.4 that the composition $\phi \circ \psi$ is equivalent to the identity on $\text{Exc}^*_n(C, D)$. We will complete the proof by showing that $\psi \circ \phi$ is equivalent to the identity functor. Consider an object $Y \in E$, corresponding to a diagram of reduced functors $E \rightarrow H \leftarrow H_0$ where $E$ is $(n-1)$-excisive, $H$ is $n$-homogeneous, and $H_0$ carries every object of $C$ to an initial object of $D$. Consider the diagram of functors $\sigma$:

\[
\begin{array}{cccc}
P_{n-1}(E) & \xrightarrow{P_{n-1}(H)} & P_{n-1}(H_0) & \\
\downarrow & & \downarrow & \\
R(E) & \xrightarrow{R(H)} & R(H_0) & \\
\downarrow & & \downarrow & \\
K(E) & \xrightarrow{K(H)} & K(H_0) & \\
\end{array}
\]

Assertion (1) of Theorem 6.1.2.4 implies that $K(E)$, $K(H)$, and $K(H_0)$ are final objects of $\text{Fun}_*(C, D)$. Since $P_{n-1}$ and $R$ are left exact, the object $P_{n-1}(H_0)$ and $R(H_0)$ are final in $\text{Fun}_*(C, D)$. The object $P_{n-1}(H) \in \text{Fun}_*(C, D)$ is final since $H$ is $n$-homogeneous, and the object $R(E) \in \text{Fun}_*(C, D)$ is final by part (4) of Theorem 6.1.2.4. Since $E$, $H$, and $H_0$ are $n$-excisive, taking the limits along the columns of the diagram $\sigma$ yields the diagram $E \rightarrow H \leftarrow H_0$ given by $Y$. Since $P_{n-1}$, $R$, and $K$ are left exact functors, taking the limits along the rows of the diagram $\sigma$ gives the diagram $(\psi \circ \phi)(Y)$:

$P_{n-1}(E \times_H H_0) \rightarrow R(E \times_H H_0) \leftarrow K(E \times_H H_0)$.

Invoking Lemma 6.1.2.6, we obtain an equivalence $Y \simeq (\psi \circ \phi)(Y)$, depending functorially on $Y$. 

\[\square\]
In the situation of Theorem 6.1.2.5, suppose that $F : \mathcal{C} \to \mathcal{D}$ is given by the fiber product $E \times_H H_0$ of a diagram in $\mathcal{E}$. Then $P_{n-1}F \simeq P_{n-1}E \times_{P_{n-1}H} P_{n-1}H_0 \simeq P_{n-1}E \simeq E$. In particular, $F$ is $n$-homogeneous if and only if $E$ is a final object of $\text{Fun}_*(\mathcal{C}, \mathcal{D})$. We therefore have the following specialization of Theorem 6.1.2.5:

**Corollary 6.1.2.7.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ be a differentiable $\infty$-category, and let $n \geq 1$ be an integer. Let $\mathcal{E}_0$ be the full subcategory of $\text{Fun}(\Lambda^n_2, \text{Fun}_*(\mathcal{C}, \mathcal{D}))$ spanned by those diagrams of functors

$$H_1 \to H \leftarrow H_0$$

where $H$ is $n$-homogeneous and the functors $H_0$ and $H_1$ carry each object of $\mathcal{C}$ to a final object of $\mathcal{D}$. Then the construction

$$\lim : \text{Fun}(\Lambda^n_2, \text{Fun}_*(\mathcal{C}, \mathcal{D})) \to \text{Fun}_*(\mathcal{C}, \mathcal{D})$$

induces an equivalence $\mathcal{E}_0 \to \text{Homog}^n(\mathcal{C}, \mathcal{D})$.

An important special case of Corollary 6.1.2.7 occurs when the $\infty$-category $\mathcal{D}$ is pointed: that is, the final objects of $\mathcal{D}$ are also initial. In this case, the $\infty$-category $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ is also pointed. We may therefore identify the $\infty$-category $\mathcal{E}_0$ with $\text{Homog}^n(\mathcal{C}, \mathcal{D})$ (by means of the evaluation functor $(H_1 \to H \leftarrow H_0) \mapsto H$), which is a trivial Kan fibration by Proposition T.4.3.2.15. Corollary 6.1.2.7 now asserts that the loop functor $\Omega : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}_*(\mathcal{C}, \mathcal{D})$ restricts to an equivalence of $\infty$-categories $\Omega : \text{Homog}^n(\mathcal{C}, \mathcal{D}) \to \text{Homog}^n(\mathcal{C}, \mathcal{D})$. Combining this observation with Corollary 1.4.2.27, we obtain the following generalization of Proposition 1.4.2.16:

**Corollary 6.1.2.8.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ be a pointed differentiable $\infty$-category, and let $n \geq 1$ be an integer. Then the $\infty$-category $\text{Homog}^n(\mathcal{C}, \mathcal{D})$ is stable.

In the situation of Corollary 6.1.2.8, let $\text{Sp}(\mathcal{D})$ denote the $\infty$-category of spectrum objects of $\mathcal{D}$ (Definition 1.4.2.8), which we regard as a full subcategory of $\text{Fun}(S^\infty_*, \mathcal{D})$. For every pointed finite space $K \in S^\infty_*$, the evaluation $X \mapsto X(K)$ determines a functor $e_K : \text{Sp}(\mathcal{D}) \to \mathcal{D}$. Note that $\text{Sp}(\mathcal{D})$ is closed under finite limits and sequential colimits in $\text{Fun}(S^\infty_*, \mathcal{D})$. For every functor $F : \mathcal{C} \to \text{Sp}(\mathcal{D})$, we have canonical equivalences

$$e_K \circ (P_n F) \simeq P_n(e_K \circ F) \quad e_K \circ (P_{n-1} F) \simeq P_{n-1}(e_K \circ F)$$

(see Remark 6.1.1.32). It follows that $F$ is $n$-excisive if and only if each of the functors $e_K \circ F$ is $n$-excisive, and $n$-reduced if and only if each of the functors $e_K \circ F$ is $n$-reduced. We therefore have canonical isomorphisms

$$\text{Exc}^n_{*}(\mathcal{C}, \text{Sp}(\mathcal{D})) \simeq \text{Sp}(\text{Exc}^n_{*}(\mathcal{C}, \mathcal{D})) \quad \text{Homog}^n(\mathcal{C}, \text{Sp}(\mathcal{D})) \simeq \text{Sp}(\text{Homog}^n(\mathcal{C}, \mathcal{D})).$$

Combining this second isomorphism, Proposition 1.4.2.21, and Corollary 6.1.2.8, we obtain the following result:

**Corollary 6.1.2.9.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ be a pointed differentiable $\infty$-category, and let $n \geq 1$ be an integer. Then composition with the functor $\Omega^\infty : \text{Sp}(\mathcal{D}) \to \mathcal{D}$ induces an equivalence of $\infty$-categories

$$\text{Homog}^n(\mathcal{C}, \text{Sp}(\mathcal{D})) \to \text{Homog}^n(\mathcal{C}, \mathcal{D}).$$

**Remark 6.1.2.10.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and a final object, and let $\mathcal{D}$ be a pointed differentiable $\infty$-category. Then the $\infty$-category $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ is also pointed. For $n \geq 1$ and $F \in \text{Fun}_*(\mathcal{C}, \mathcal{D})$, let $U(F)$ denote the fiber of the map $F \to P_{n-1}(F)$. Since the functor $P_{n-1}$ is left exact, $P_{n-1}U(F)$ is the fiber of the equivalence $P_{n-1}(F) \to P_{n-1}P_{n-1}(F)$. It follows that $U(F)$ is $n$-reduced. If $G : \mathcal{C} \to \mathcal{D}$ is any $n$-reduced functor, then $\text{Map}_{\text{Fun}_*(\mathcal{C}, \mathcal{D})}(G, P_{n-1}F) \simeq \text{Map}_{\text{Fun}_*(\mathcal{C}, \mathcal{D})}(P_{n-1}G, P_{n-1}F)$ is contractible, so that the canonical map

$$\text{Map}_{\text{Fun}_*(\mathcal{C}, \mathcal{D})}(G, U(F)) \to \text{Map}_{\text{Fun}_*(\mathcal{C}, \mathcal{D})}(G, F)$$
is a homotopy equivalence. It follows that the construction \( F \mapsto U(F) \) is a right adjoint to the inclusion from the \( \infty \)-category of \( n \)-reduced functors to the \( \infty \)-category of all functors from \( \mathcal{C} \) to \( \mathcal{D} \). Note that if \( F \) is \( n \)-excisive, then \( U(F) \) is also \( n \)-excisive (and therefore \( n \)-homogeneous).

Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and a final object, and let \( \mathcal{C}_+ \) be the \( \infty \)-category of pointed objects of \( \mathcal{C} \). The forgetful functor \( \theta : \mathcal{C}_+ \to \mathcal{C} \) preserves final objects and strongly coCartesian cubes. It follows that for any differentiable \( \infty \)-category \( \mathcal{D} \), composition with \( \theta \) induces a functor \( \nu : \text{Exc}^n(\mathcal{C}_+, \mathcal{D}) \to \text{Exc}^n(\mathcal{C}_+, \mathcal{D}) \). Using Remark 6.1.1.30, we obtain an equivalence equivalence \( P_n(F \circ \theta) \simeq P_n(F) \circ \theta \) for every functor \( F : \mathcal{C} \to \mathcal{D} \). In particular, if \( F \) is \( n \)-reduced, then \( F \circ \theta \) is also \( n \)-reduced. Consequently, \( \nu \) restricts to a map \( \text{Homog}^n(\mathcal{C}, \mathcal{D}) \to \text{Homog}^n(\mathcal{C}_+, \mathcal{D}) \).

**Proposition 6.1.2.11.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and a final object, and let \( \mathcal{D} \) be a pointed differentiable \( \infty \)-category. For each integer \( n \geq 1 \), composition with the forgetful functor \( \mathcal{C}_+ \to \mathcal{C} \) induces an equivalence of \( \infty \)-categories \( \phi : \text{Homog}^n(\mathcal{C}, \mathcal{D}) \to \text{Homog}^n(\mathcal{C}_+, \mathcal{D}) \).

**Proof.** We have a commutative diagram:

\[
\begin{array}{ccc}
\text{Homog}^n(\mathcal{C}, \text{Sp}(\mathcal{D})) & \longrightarrow & \text{Homog}^n(\mathcal{C}_+, \text{Sp}(\mathcal{D})) \\
\downarrow & & \downarrow \\
\text{Homog}^n(\mathcal{C}, \mathcal{D}) & \longrightarrow & \text{Homog}^n(\mathcal{C}_+, \mathcal{D})
\end{array}
\]

where the vertical maps are equivalences by Corollary 6.1.2.9. We may therefore replace \( \mathcal{D} \) by \( \text{Sp}(\mathcal{D}) \) and thereby reduce to the case where \( \mathcal{D} \) is stable.

Let \( * \) denote the final object of \( \mathcal{C} \). Since \( \mathcal{C} \) admits finite colimits, the forgetful functor \( \mathcal{C}_+ \to \mathcal{C} \) admits a left adjoint, given by \( X \mapsto X_+ = X \sqcup * \). Composition with this left adjoint determines a functor \( \psi_0 : \text{Fun}(\mathcal{C}_+, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D}) \). Since the construction \( X \mapsto X_+ \) preserves finite colimits, \( \psi_0 \) restricts to a functor \( \psi_1 : \text{Exc}^n(\mathcal{C}_+, \mathcal{D}) \to \text{Exc}^n(\mathcal{C}, \mathcal{D}) \), which is right adjoint to the forgetful functor \( \text{Ext}^{(n)}(\mathcal{C}, \mathcal{D}) \to \text{Exc}^{(n)}(\mathcal{C}_+, \mathcal{D}) \).

Let \( U \) be as in Remark 6.1.2.10, and let \( \psi \) denote the composition

\[
\text{Homog}^n(\mathcal{C}_+, \mathcal{D}) \subseteq \text{Exc}^n(\mathcal{C}_+, \mathcal{D}) \overset{\psi_1}{\to} \text{Exc}^n(\mathcal{C}, \mathcal{D}) \overset{U}{\to} \text{Homog}^n(\mathcal{C}, \mathcal{D}),
\]

so that \( \psi \) is right adjoint to \( \phi \).

We next prove that for every \( F \in \text{Homog}^n(\mathcal{C}, \mathcal{D}) \), the unit map \( u : F \to \psi \circ F \) is an equivalence. We first prove that \( u \) is an equivalence. By assumption, \( F \) is \( n \)-reduced. Consequently, we can identify \( u \) with \( U(u_0) \), where \( u_0 \) is the unit map \( F \to \psi_0 \circ F \). Since \( \mathcal{D} \) is stable, to prove that \( u \) is an equivalence, it will suffice to show that \( \text{fib}(u_0) \) is \((n-1)\)-excisive. Let \( S = [n-1] = \{1, \ldots, n-1\} \) and let \( X \) be a strongly coCartesian \( S \)-cube in \( \mathcal{C} \); we wish to show that \( \text{fib}(u_0)(X) \) is a Cartesian \( S \)-cube in \( \mathcal{D} \). Let \( S_+ = [n] = S \cup \{n\} \), and let \( Y \) be the strongly coCartesian \( S \)-cube given by

\[
Y(T) = \begin{cases} 
X(T) & \text{if } n \notin T \\
X(T)_+ & \text{if } n \in T.
\end{cases}
\]

To prove that \( \text{fib}(u_0)(X) \) is a Cartesian \( S \)-cube, it suffices to show that \( F(Y) \) is a Cartesian \( S_+ \). Since \( F \) is \( n \)-excisive, it suffices to show that \( Y \) is a strongly coCartesian \( S \)-cube, which is clear.

It follows from the above argument that the functor \( \phi \) is fully faithful. To complete the proof, we will show that the functor \( \psi \) is conservative. Because \( \psi \) is an exact functor between stable \( \infty \)-categories, it will suffice to show that if \( G \in \text{Homog}^n(\mathcal{C}_+, \mathcal{D}) \) satisfies \( \psi_1 G \simeq 0 \), then \( G \) is a zero object of \( \text{Homog}^{(n)}(\mathcal{C}_+, \mathcal{D}) \). The assumption that \( \psi_1 G \simeq 0 \) implies that the canonical map \( \psi_1 G \to P_{n-1}(\psi_1 G) \) is an equivalence; that is, \( \psi_1 G \) is \((n-1)\)-excisive. We will show that \( G \) is \((n-1)\)-excisive: combined with our assumption that \( G \) is \((n-1)\)-reduced, this will allow us to conclude that \( G \) is a zero object of \( \text{Homog}^n(\mathcal{C}, \mathcal{D}) \).
Let $S = [n - 1] = \{0, \ldots, n - 1\}$ and let $X : N(P(S)) \to \mathcal{C}_*$ be a strongly coCartesian $S$-cube. Let $S_+ = [n] = S \cup \{n\}$ and let $Y : N(P(S_+)) \to \mathcal{C}_*$ be defined by the formula

$$ Y(T) = \begin{cases} (\theta X(T))_+ & \text{if } n \notin T \\ X(T - \{n\}) & \text{if } n \in T. \end{cases} $$

The assumption that $X$ is a strongly coCartesian $S$-cube implies that $Y$ is a strongly coCartesian $S_+$-cube. Since $G$ is $n$-excisive, we conclude that $G(Y)$ is a Cartesian $S_+$-cube in $\mathcal{D}$. It follows that the diagram

$$ \begin{array}{ccc} G(Y(\emptyset)) & \longrightarrow & G(Y(\{n\})) \\ \downarrow & & \downarrow \\ \lim_{\emptyset \neq T \subseteq S} G(Y(T)) & \longrightarrow & \lim_{\emptyset \neq T \subseteq S} G(Y(T \cup \{n\})) \end{array} $$

is a pullback square in $\mathcal{D}$. The assumption that $\psi_1 G$ is $(n - 1)$-excisive implies that the left vertical map is an equivalence. Using the stability of $\mathcal{D}$, we conclude that the right vertical map is also an equivalence: that is, $G(X)$ is a Cartesian $S$-cube.

We now turn to the proof of Theorem 6.1.2.4. We will need a rather elaborate construction. Fix an integer $m \geq 0$. Let $P = P_{>0}([n])$ denote the partially ordered set of nonempty subsets of the set $[n] = \{0, \ldots, n\}$. We define a functor $\chi_m : N(P)^m \times \text{Fun}_*(\mathcal{C}, \mathcal{D}) \to \text{Fun}_*(\mathcal{C}, \mathcal{D})$ by the formula

$$ \chi_i(S_1, \ldots, S_m, F) = F \circ C_{S_1} \circ \cdots \circ C_{S_m}, $$

where the functors $C_T : \mathcal{C} \to \mathcal{C}$ are defined as in Construction 6.1.1.18. For every subset $I \subseteq P^m$, let $U_I : \text{Fun}_*(\mathcal{C}, \mathcal{D}) \to \text{Fun}_*(\mathcal{C}, \mathcal{D})$ be given by the formula

$$ U_I(F) = \lim_{\lim} \chi_m|N(I) \times \{F\}). $$

**Remark 6.1.2.12.** Suppose we are given subsets $I \subseteq P^m$ and $I' \subseteq P^{m'}$. Then we can identify $I \times I'$ with a subset of $P^{m+m'}$. Moreover, we have a canonical equivalence of functors $U_{I \times I'} \simeq U_{I'} \circ U_I$ from $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ to itself.

Let $B \subseteq P$ be the collection of those subsets $S \subseteq [n]$ having nonempty intersection with $[n - 1] = \{0, \ldots, n - 1\} \subseteq \{0, \ldots, n\} \subseteq [n]$. For each integer $m \geq 0$, let $A_m \subseteq P^m$ denote the collection of tuples $(S_1, \ldots, S_m)$ such that at least one of the sets $S_i$ contains $n \in [n]$. We have a commutative diagram of subsets of $P^{m+1}$:

$$ \begin{array}{ccc} P^{m+1} & \leftarrow & B^m \times P \leftarrow B^{m+1} \\ A_{m+1} & \leftarrow & A_{m+1} \cap (B^m \times P) \leftarrow A_{m+1} \cap B^{m+1} \\ A_m \times P & \leftarrow & (A_m \cap B^m) \times P \end{array} $$

which determines a commutative diagram of left exact functors $\tau_m$:

$$ \begin{array}{ccc} U_{P^{m+1}} & \longrightarrow & U_{B^m \times P} \longrightarrow U_{B^{m+1}} \\ U_{A_{m+1}} & \longrightarrow & U_{A_{m+1} \cap (B^m \times P)} \longrightarrow U_{A_{m+1} \cap B^{m+1}} \\ U_{A_m \times P} & \longrightarrow & U_{(A_m \cap B^m) \times P} \end{array} $$

$$ \phi \quad \phi' \quad $$
from \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) to itself.

**Lemma 6.1.2.13.** For each \( m \geq 0 \), the functor \( U_{A_m} : \text{Fun}_*(\mathcal{C}, \mathcal{D}) \to \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) carries each \( F \in \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) to a final object of \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \).

*Proof.* Let \( A'_m = \mathcal{P}^m - B^m \). We claim that the inclusion of simplicial sets \( N(A'_m) \to N(A_m) \) is right cofinal. To prove this, consider a sequence \( (S_1, \ldots, S_n) \in A_m \), and let \( W = \{ (S'_1, \ldots, S'_n) \in A'_m : (\forall 1 \leq i \leq n)[S'_i \subseteq S_i] \} \). According to Theorem T.4.1.3.1, it will suffice to show that the partially ordered set \( W \) has weakly contractible nerve. Let \( I \subseteq \{ 1, \ldots, m \} \) be the set of indices for which \( n \in S_i \). For every subset \( J \subseteq I \), let \( W_J \) denote the subset of \( W \) consisting of those tuples \( (S'_1, \ldots, S'_n) \) such that \( S'_j = \{ n \} \) for \( j \in J \). Then \( N(W) \) is the homotopy limit of the diagram of simplicial sets \( \{ N(W_J) \}_{\emptyset \neq J \subseteq I} \). Since \( I \) is nonempty, it will suffice to show that each of the simplicial set \( N(W_J) \) is contractible. This is clear, since \( W_J \) has a largest element (namely, the tuple \( (S'_1, \ldots, S'_n) \) with \( S'_i = \begin{cases} \{ n \} & \text{if } i \in J \\ S_i & \text{otherwise.} \end{cases} \)).

It follows from the above argument that the inclusion \( A'_m \hookrightarrow A_m \) induces an equivalence \( U_{A_m}(F) \to U_{A'_m}(F) \) for every \( F \in \text{Fun}_*(\mathcal{C}, \mathcal{D}) \). Note that if \( (S_1, \ldots, S_n) \in A'_m \), then at least one of the sets \( S_i \) is a singleton, so that the composite functor \( C_{S_1} \circ \cdots \circ C_{S_m} : \mathcal{C} \to \mathcal{C} \) carries each object of \( \mathcal{C} \) to a final object of \( \mathcal{C} \). Since \( F \) is reduced, it follows that

\[
U_{A'_m}(F) = \lim_{(S_1, \ldots, S_n) \in A'_m} (F \circ C_{S_1} \circ \cdots \circ C_{S_n})
\]

carries each object of \( \mathcal{C} \) to a final object of \( \mathcal{D} \), as desired. \( \square \)

**Lemma 6.1.2.14.** In the above diagram, the maps \( \phi \) and \( \phi' \) are equivalences of functors from \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) to itself.

*Proof.* We will prove that the map \( \phi \) is an equivalence; the proof for \( \phi' \) is similar. Observe that \( N(A_{m+1}) \) is the union of the simplicial subsets \( N(A_m \times \mathcal{P}) \) and \( N(B^m \times A_1) \), whose intersection is \( N((B^m \cap A_m) \times A_1) \). Using the results of §T.4.2.3, we deduce that the diagram of functors

\[
\begin{array}{ccc}
U_{A_{m+1}} & \longrightarrow & UB^m \times A_1 \\
\phi \downarrow & & \psi \\
U_{A_m \times \mathcal{P}} & \longrightarrow & UB^m \cap A_m \times A_1
\end{array}
\]

is a pullback square. It will therefore suffice to show that \( \psi \) is an equivalence. Note that \( UB^m \times A_1 \simeq U_{A_1} \circ UB^m \) (Remark 6.1.2.12), and therefore carries each \( F \in \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) to a final object of \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) (Lemma 6.1.2.13). The same argument shows that \( U(B^m \cap A_m) \times A_1 \) carries each \( F \in \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) to a final object of \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \), so that \( \psi \) is an equivalence as desired. \( \square \)

*Proof of Theorem 6.1.2.4.* For each \( m \geq 0 \), let \( \sigma_m \) be the diagram

\[
\begin{array}{ccc}
U_{\mathcal{P}^m} & \longrightarrow & UB^m \\
\downarrow & & \downarrow \\
U_{A_m} & \longrightarrow & UB^m \cap A_m
\end{array}
\]

of functors from the \( \infty \)-category \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) to itself. Let \( T_n : \text{Fun}_*(\mathcal{C}, \mathcal{D}) \to \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) be defined as in Construction 6.1.1.22, so that \( T_n \simeq U_{\mathcal{P}^n} \). Using Remark 6.1.2.12 and Lemma 6.1.2.14, we can identify \( T_n \sigma_m \) with the commutative diagram

\[
\begin{array}{ccc}
U_{\mathcal{P}^{m+1}} & \longrightarrow & UB^m \times \mathcal{P} \\
\downarrow & & \downarrow \\
U_{A_{m+1}} & \longrightarrow & U_{A_{m+1} \cap (B^m \times \mathcal{P})}.
\end{array}
\]
so that the commutative diagram $\tau_m$ above induces a natural transformation $\alpha_m : T_n(\sigma_m) \rightarrow \sigma_{m+1}$. Let $\sigma_\infty$ denote a colimit of the sequence

$$\sigma_0 \rightarrow T_n(\sigma_0) \overset{\alpha^1}{\rightarrow} \sigma_1 \rightarrow T_n(\sigma_1) \overset{\alpha^2}{\rightarrow} \sigma_2 \rightarrow \cdots$$

Then $\sigma_\infty$ is a commutative diagram of functors

$$\begin{array}{ccc}
P & \longrightarrow & P' \\
\downarrow & & \downarrow \\
K & \longrightarrow & R
\end{array}$$

from $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ to itself. We claim that this commutative diagram has the desired properties.

Using the fact that $U_\mathcal{P} = T_n$ and Remark 6.1.2.12, we see that $U_{\mathcal{P}^m}$ can be identified with $T_n^{m^\infty}$. Unwinding the definitions, we deduce that $P$ is the colimit of the sequence of functors

$$\text{id} \rightarrow T_n \rightarrow T_n^2 \rightarrow \cdots,$$

and can therefore be identified with the functor $P_n$ of Construction 6.1.1.27. There is an evident inclusion of partially ordered sets $\mathbf{P}_{> 0}([n-1]) \hookrightarrow B$, which induces a right cofinal map of simplicial sets $N(\mathbf{P}_{> 0}([n-1])) \hookrightarrow N(B)$. It follows that $U_B \simeq U_{N(\mathbf{P}_{> 0}([n-1]))}$ can be identified with the functor $T_{n-1} : \text{Fun}_*(\mathcal{C}, \mathcal{D}) \rightarrow \text{Fun}_*(\mathcal{C}, \mathcal{D})$. Using Remark 6.1.2.12, we obtain an equivalence of functors $U_{B^m} \simeq T_{n-1}^m$. The functor $P'$ can be identified with the colimit of the sequence of functors

$$\text{id} \rightarrow T_{n-1} \rightarrow T_{n-1}^2 \rightarrow T_{n-1}^3 \rightarrow \cdots,$$

which is the functor $P_{n-1}$ of Construction 6.1.1.27. Lemma 6.1.2.13 implies that $K$ is the colimit of a sequence of functors which carry every functor $F \in \text{Fun}_*(\mathcal{C}, \mathcal{D})$ to a final object of $\text{Fun}_*(\mathcal{C}, \mathcal{D})$. It follows that $K$ carries every functor $F \in \text{Fun}_*(\mathcal{C}, \mathcal{D})$ to a final object of $\text{Fun}_*(\mathcal{C}, \mathcal{D})$. We can therefore identify $\sigma_\infty$ with a commutative diagram

$$\begin{array}{ccc}
P_n & \longrightarrow & P_{n-1} \\
\downarrow & & \downarrow \\
K & \longrightarrow & R
\end{array}$$

Note that for $I \subseteq \mathbf{P}^m$, the functor $U_I : \text{Fun}_*(\mathcal{C}, \mathcal{D}) \rightarrow \text{Fun}_*(\mathcal{C}, \mathcal{D})$ is a limit of functors which preserve finite limits, and is therefore itself preserve finite limits. Since finite limits in $\mathcal{D}$ commute with sequential colimits, finite limits in $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ commute with sequential colimits. In particular, the collection of functors from $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ to itself which commute with finite limits is closed under sequential colimits, so that $R$ preserves finite limits.

We now prove that $\sigma_\infty$ is a pullback square. Since finite limits in $\mathcal{D}$ commute with sequential colimits, the collection of pullback square in $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ is closed under sequential colimits. It will therefore suffice to show that each $\sigma_m$ is a pullback square of functors from $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ to itself. This follows from the results of §T.4.2.3, since the simplicial set $N(\mathbf{P}^m)$ is the union of the simplicial subsets $N(B^m)$ and $N(A_m)$ having intersection $N(B^m \cap A_m)$.

We next prove that if $F : \mathcal{C} \rightarrow \mathcal{D}$ is reduced and $(n-1)$-excisive, then $R(F)$ is a final object of $\text{Fun}_*(\mathcal{C}, \mathcal{D})$. Since we can write $R(F)$ as the colimit of a sequence of functors $U_{B^m \cap A_m}(F)$, it will suffice to show that each $U_{B^m \cap A_m}(F)$ is a final object of $\text{Fun}_*(\mathcal{C}, \mathcal{D})$. There is an isomorphism of partially ordered sets

$$B^m \cap A_m \simeq \mathbf{P}_{> 0}([n-1]) \times \mathbf{P}_{> 0}\{1, \ldots, m\},$$

given by

$$(S_1, \ldots, S_m) \mapsto (S_1 \cap [n-1], \ldots, S_m \cap [n-1], \{i : n \in S_i\})$$
We may therefore write \( U_{B \cap A_m}(F) \) as a limit of a diagram
\[
G : N(P_{>0}([n-1]))^m \times N(P_{>0}\{1, \ldots, m\}) \to \text{Fun}_*(\mathcal{C}, \mathcal{D}).
\]
For every nonempty subset \( T \subseteq \{1, \ldots, m\} \), let \( G_T \) denote the restriction of \( G \) to \( N(P_{>0}([n-1]))^m \times \{T\} \). Then \( U_{B \cap A_m}(F) \) can be written as the limit \( \lim_{\emptyset \neq T \subseteq \{1, \ldots, m\}} \lim G_T \). It will therefore suffice to show that each of the functors \( \lim G_T \) is a final object of \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \). Using our assumption that \( F \) is \((n-1)\)-excisive, we obtain a canonical equivalence
\[
\lim G_T \simeq F \circ C_{S_1} \circ \cdots \circ C_{S_m},
\]
where \( S_i = \{n\} \) if \( i \in T \) and \( \emptyset \) if \( i \notin T \). Since \( T \) is nonempty, at least one of the functors \( C_{S_i} \) carries every object of \( \mathcal{C} \) to the final object (see Example 6.1.1.23). Using our assumption that \( F \) is reduced, we conclude that \( \lim G_T \) carries every object of \( \mathcal{C} \) to a final object in \( \mathcal{D} \). This completes the proof that \( R(F) \) is a final object of \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \) whenever \( F \) is \((n-1)\)-excisive.

We complete the proof by showing that for an arbitrary functor \( F \in \text{Fun}_*(\mathcal{C}, \mathcal{D}) \), the functor \( R(F) \) is \( n \)-homogeneous. Note that we have a canonical equivalence
\[
P_{n-1}(R(F)) \simeq R(P_{n-1}F).
\]
Since \( P_{n-1}F \) is reduced and \( n \)-excisive, \( R(P_{n-1}F) \) is a final object of \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \), so that \( R(F) \) is \( n \)-reduced. It will therefore suffice to show that \( R(F) \) is \( n \)-excisive. Let \( S = [n] \) and let \( X : NP(S) \to \mathcal{C} \) be a strongly coCartesian \( n \)-cube. Then \( (R(F))(X) \) is given by the colimit of a sequence of \( S \)-cubes
\[
U_{B^0 \cap A_0}(F)(X) \overset{\beta_0}{\to} T_n(U_{B^0 \cap A_0}(F))(X) \to U_{B^1 \cap A_1}(F)(X) \overset{\beta_1}{\to} T_n(U_{B^1 \cap A_1}(F))(X) \to \ldots
\]
According to Lemma 6.1.1.26, each of the maps \( \beta_i \) factors through a Cartesian \( S \)-cube. It follows that \( (R(F))(X) \) can be written as the colimit of a sequence of Cartesian \( S \)-cubes, and is therefore Cartesian (since finite colimits in \( \mathcal{D} \) commute with sequential limits).

### 6.1.3 Functors of Many Variables

Suppose we are given a functor \( F : \mathcal{C}_- \times \mathcal{C}_+ \to \mathcal{D} \) between \( \infty \)-categories. We can think about \( F \) in several different ways:

(a) We can understand \( F \) as a family of functors \( \mathcal{C}_+ \to \mathcal{D} \), parametrized by the objects of \( \mathcal{C}_- \).

(b) We can understand \( F \) as a family of functors \( \mathcal{C}_- \to \mathcal{D} \), parametrized by the objects of \( \mathcal{C}_+ \).

(c) We can understand \( F \) as a single functor \( \mathcal{C} \to \mathcal{D} \), where \( \mathcal{C} \) denotes the product \( \mathcal{C}_- \times \mathcal{C}_+ \).

The ideas of §6.1.1 and 6.1.2 can be applied from each of these perspectives, to obtain several different notions of what it means for \( F \) to be reduced, excisive and homogeneous. Our goal in this section is to study the relationships between these notions. We begin by introducing some terminology.

**Definition 6.1.3.1.** Suppose we are given \( \infty \)-categories \( \mathcal{C}_1, \mathcal{C}_2, \ldots, \mathcal{C}_m \) which admit pushouts, and an \( \infty \)-category \( \mathcal{D} \) which admits finite limits, and a sequence of nonnegative integers \( \vec{n} = (n_1, \ldots, n_m) \). We will say that a functor \( F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D} \) is \( \vec{n} \)-excisive if, for all \( 1 \leq i \leq m \) and every sequence of objects \( \{X_j \in \mathcal{C}_j\}_{j \neq i} \), the induced functor
\[
\mathcal{C}_i \hookrightarrow \mathcal{C}_i \times \prod_{j \neq i} \{X_j\} \hookrightarrow \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \xrightarrow{F} \mathcal{D}
\]
is \( n_i \)-excisive. We let \( \text{Exc}^{\vec{n}}(\prod \mathcal{C}_i, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\prod \mathcal{C}_i, \mathcal{D}) \) spanned by those functors which are \( \vec{n} \)-excisive. In the special case where \( \vec{n} = (1,1,\ldots,1) \), we will denote \( \text{Exc}^{\vec{n}}(\prod \mathcal{C}_i, \mathcal{D}) \) by \( \text{Exc}(\prod \mathcal{C}_i, \mathcal{D}) \).
Warning 6.1.3.2. The notation of Definition 6.1.3.1 is potentially ambiguous. Suppose we are given a finite collection of ∞-categories \( \{ \mathcal{C}_s \}_{s \in S} \) which admit pushouts, and let \( \mathcal{C} = \prod_{s \in S} \mathcal{C}_s \). Then \( \text{Exc}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) and \( \text{Exc}(\mathcal{C}, \mathcal{D}) \) denote two different ∞-categories: \( \text{Exc}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) is the full subcategory of \( \text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) spanned by those functors which are excisive separately in each variable, while \( \text{Exc}(\mathcal{C}, \mathcal{D}) \) denotes the full subcategory of \( \text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) spanned by those functors which are excisive when viewed as a functor of a single variable.

Remark 6.1.3.3. In the situation of Definition 6.1.3.1, suppose that \( m > 0 \) and set \( \vec{n}'' = (n_2, \ldots, n_m) \). We then have a canonical isomorphism

\[
\text{Exc}^{\vec{n}''}(\prod_{1 \leq i \leq m} \mathcal{C}_i, \mathcal{D}) \cong \text{Exc}^{n_1}(\mathcal{C}_1, \mathcal{D}),
\]

Proposition 6.1.3.4. Let \( \mathcal{C}_1, \ldots, \mathcal{C}_m \) be ∞-categories which admit finite colimits, \( \mathcal{D} \) an ∞-category which admits finite limits, and \( F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D} \) an \( (n_1, \ldots, n_m) \)-excisive functor. Then \( F \) is \( n \)-excisive when regarded as a functor of one variable (with values in \( \mathcal{C} = \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \)), where \( n = n_1 + \cdots + n_m \).

Corollary 6.1.3.5. Let \( \mathcal{C} \) be an ∞-category which admits finite colimits, \( \delta : \mathcal{C} \to \mathcal{C}^m \) the diagonal map, \( \mathcal{D} \) a functor which admits finite limits, and \( F : \mathcal{C}^m \to \mathcal{D} \) an \( (n_1, \ldots, n_m) \)-excisive functor. Then \( F \circ \delta \) is \( n \)-excisive, where \( n = n_1 + \cdots + n_m \).

Proof. Combine Proposition 6.1.3.4 with the observation that the diagonal map \( \delta \) preserves strongly co-Cartesian cubes.

Proof of Proposition 6.1.3.4. Let \( S = [n] = \{0, \ldots, n\} \) and let \( X : N(P(S)) \to \mathcal{C} \) be a strongly coCartesian \( S \)-cube in \( \mathcal{C} \), corresponding to a sequence of strongly coCartesian \( S \)-cubes \( \{X_i : N(P(S)) \to \mathcal{C}_i\}_{1 \leq i \leq m} \). Let \( \delta_0 : N(P(S)) \to N(P(S)^m) \) be the diagonal map. We wish to show that the composition

\[
N(P(S)) \xrightarrow{\delta_0} N(P(S)^m) \xrightarrow{\prod X_i} \mathcal{C} \xrightarrow{F} \mathcal{D}
\]

is a Cartesian \( S \)-cube in \( \mathcal{D} \).

Let \( A \subseteq P(S)^m \) be the image of \( P_{>0}(S) \) under the map \( \delta_0 \): that is, \( A \) is the collection of sequences \( (S_1, \ldots, S_m) \) where \( S_1 = S_2 = \cdots = S_m \) is a nonempty subset of \( S \). Let \( Y : N(P(S)^m) \to \mathcal{D} \) be the composition of \( F \) with \( \prod X_i \). We wish to show that \( Y \) exhibits \( Y(\emptyset, \ldots, \emptyset) \) as a limit of the diagram \( Y|N(A) \).

Let \( B \subseteq P(S)^m \) be the collection of sequences \( (S_1, \ldots, S_m) \) for which the intersection \( S_1 \cap \cdots \cap S_m \) is nonempty. Then \( A \subseteq B \). Moreover, the inclusion \( A \subseteq B \) admits a right adjoint, given by \( (S_1, \ldots, S_m) \mapsto (T, \ldots, T) \) where \( T = \bigcap S_i \). It follows that the canonical map \( \lim Y|N(B) \to \lim Y|N(A) \) is an equivalence. It will therefore suffice to show that \( Y \) exhibits \( Y(\emptyset, \ldots, \emptyset) \) as a limit of the diagram \( Y|N(B) \). We will prove a stronger assertion: namely, that the functor \( Y \) is a right Kan extension of \( Y|N(B) \).

Choose a sequence of subsets

\[
B = B_0 \subseteq B_1 \subseteq B_2 \subseteq \cdots \subseteq B_k = P(S)^m
\]

so that the following conditions are satisfied:

(a) Each \( B_j \) is closed upwards in the partially ordered set \( P(S)^m \) (that is, if \( (S_1, \ldots, S_m) \in B_j \) and \( S_i \subseteq S'_i \subseteq S \), then \( (S'_1, \ldots, S'_m) \in B_j \)).

(b) For \( 0 < j \leq k \), the set \( B_j \) is obtained from \( B_{j-1} \) by adding a single element \( (S_1, \ldots, S_m) \in P(S)^m \).

To prove that \( Y \) is a right Kan extension of \( Y|N(B_j) \), it will suffice to show that \( Y|N(B_j) \) is a right Kan extension of \( Y|N(B_{j-1}) \) for \( 0 < j \leq k \). Let us suppose that \( B_j \) is obtained from \( B_{j-1} \) by adjoining a single element \( (S_1, \ldots, S_m) \in P(S)^m \). Then \( (S_1, \ldots, S_m) \notin B_j \), so we have \( S = \bigcup_i (S - S_i) \). Since the cardinality of...
6.1. THE CALCULUS OF FUNCTORS

There is larger than \( n = n_1 + \cdots + n_m \), we conclude that there is an integer \( a \) with \( 1 \leq a \leq m \) such that \( S - S_a \) has cardinality larger than \( n_a \).

Let \( T = \prod_{1 \leq i \leq m} (S - S_i) \). Note that there is bijective correspondence between subsets of \( T \) and sequences \((S'_1, \ldots, S'_m) \in P(S)^m\) such that \( S_i \subseteq S'_i \) for all \( i \). Consequently, \( Y \) determines a \( T \)-cube \( Y_T : N(P(T)) \rightarrow D \). Using (a), we see that \( Y|N(B_j) \) is a right Kan extension of \( Y|N(B_{j-1}) \) if and only if \( Y_T \) is a Cartesian \( T \)-cube in \( D \). Let \( T_0 \) be a subset of \( S - S_a \) having cardinality \( n_a + 1 \), and regard \( T_0 \) as a subset of \( T \). According to Proposition 6.1.1.13, it will suffice to show that every \( T_0 \)-face of \( Y_T \) is Cartesian. This follows immediately from our assumption that the functor \( F \) is \( n_a \)-excisive in the \( a \)th variable.

We have the following analogue of Theorem 6.1.1.10:

**Proposition 6.1.3.6.** Let \( C_1, \ldots, C_m \) be \( \infty \)-categories which admit finite colimits and final objects, and let \( D \) be a pointed differentiable \( \infty \)-category. For every sequence of nonnegative integers \( \vec{n} = (n_1, \ldots, n_m) \), the inclusion functor \( i : \text{Exc}^\vec{n}(\prod_{1 \leq i \leq m} C_i, D) \hookrightarrow \text{Fun}(\prod_{1 \leq i \leq m} C_i, D) \) admits a left adjoint \( P_{\vec{n}} \). Moreover, the functor \( P_{\vec{n}} \) is left exact.

**Proof.** We proceed by induction on \( m \). If \( m = 0 \), then \( \text{Exc}^\vec{n}(\prod_{1 \leq i \leq m} C_i, D) = \text{Fun}(\prod_{1 \leq i \leq m} C_i, D) \) and there is nothing to prove. Assume therefore that \( m > 0 \), and set \( \vec{n}' = (n_2, \ldots, n_m) \). Using Remark 6.1.3.3, we see that \( i \) is equivalent to the composition

\[
\text{Fun}(C_1, \text{Fun}(\prod_{2 \leq i \leq m} C_i, D)) \hookrightarrow \text{Fun}(C_1, \text{Exc}^{\vec{n}'}(\prod_{2 \leq i \leq m} C_i, D)) \hookrightarrow \text{Exc}^{n_1}(C_1, \text{Exc}^{\vec{n}'}(\prod_{2 \leq i \leq m} C_i, D)).
\]

The inductive hypothesis implies that the inclusion \( \text{Exc}^{\vec{n}'}(\prod_{2 \leq i \leq m} C_i, D) \hookrightarrow \text{Fun}(\prod_{2 \leq i \leq m} C_i, D) \) admits a left exact left adjoint. It follows that \( i' \) admits a left exact left adjoint. We now complete the proof by invoking Theorem 6.1.1.10, which guarantees that \( i'' \) admits a left exact left adjoint.

We now turn our attention to reduced functors.

**Definition 6.1.3.7.** Let \( C_1, C_2, \ldots, C_m \) be \( \infty \)-category which admit finite colimits and final objects, let \( D \) be a differentiable \( \infty \)-category, and let \( \vec{n} = (n_1, \ldots, n_m) \) be a sequence of positive integers. We will say that a functor \( F : C_1 \times \cdots \times C_m \rightarrow D \) is \( \vec{n} \)-reduced if, for all \( 1 \leq i \leq m \) and every sequence of objects \( \{X_j \in C_j\}_{j \neq i} \), the induced functor

\[
C_1 \hookrightarrow C_i \times \prod_{j \neq i} X_j \hookrightarrow C_1 \times \cdots \times C_m \rightarrow D
\]

is \( n_i \)-reduced. We will say that \( F \) is \( \vec{n} \)-homogeneous if \( F \) is \( \vec{n} \)-reduced and \( \vec{n} \)-excisive.

We will say that \( F \) is reduced if it is \((1,1,\ldots,1)\)-reduced: that is, if \( F \) is reduced in each variable. We let \( \text{Fun}_*(\prod_{1 \leq i \leq m} C_i, D) \) denote the full subcategory of \( \text{Fun}(\prod_{1 \leq i \leq m} C_i, D) \) spanned by the reduced functors. We will say that \( F \) is multilinear if it is \((1,1,\ldots,1)\)-homogeneous; we let

\[
\text{Exc}_*(\prod_{1 \leq i \leq m} C_i, D) = \text{Exc}(\prod_{1 \leq i \leq m} C_i, D) \cap \text{Fun}_*(\prod_{1 \leq i \leq m} C_i, D)
\]

denote the full subcategory of \( \text{Fun}(\prod_{1 \leq i \leq m} C_i, D) \) spanned by the multilinear functors.

**Warning 6.1.3.8.** The notation of Definition 6.1.3.7 is potentially ambiguous. Given a finite collection of \( \infty \)-categories \( \{C_s\}_{s \in S} \) which admit finite colimits and final objects, set \( C = \prod_{s \in S} C_s \). Then the full subcategories \( \text{Fun}_*(\prod_{s \in S} C_s, D), \text{Exc}_*(\prod_{s \in S} C_s, D) \subseteq \text{Fun}(\prod_{s \in S} C_s, D) \) are generally different from the full subcategories \( \text{Fun}_*(C, D), \text{Exc}_*(C, D) \subseteq \text{Fun}(C, D) \) introduced in Definition 1.4.2.1. A functor \( F : C = \prod_{s \in S} C_s \rightarrow D \) belongs to \( \text{Fun}_*(\prod_{s \in S} C_s, D) \) if it is reduced (reduced and excisive) separately in each variable: it belongs to \( \text{Fun}_*(C, D) \) if it is reduced (reduced and excisive) when viewed as a functor of a single variable.
Remark 6.1.3.9. The requirement that a functor $F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}$ be reduced can be stated more simply as follows: given a collection of objects $\{X_s \in \mathcal{C}_s\}$, if any $X_s$ is a final object of $\mathcal{C}_s$, then $F(\{X_s\}_{s \in S})$ is a final object of $\mathcal{D}$.

Proposition 6.1.3.10. Let $\mathcal{C}_1, \mathcal{C}_2, \ldots, \mathcal{C}_m$ be $\infty$-category which admit finite colimits and final objects, let $\mathcal{D}$ be a differentiable $\infty$-category, and let $F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D}$ be a functor which is $(1, \ldots, 1)$-reduced. Let $\mathcal{C} = \prod_{1 \leq i \leq m} \mathcal{C}_i$. Then $F$ is $m$-reduced when viewed as a functor from $\mathcal{C}$ to $\mathcal{D}$.

Corollary 6.1.3.11. In the situation of Proposition 6.1.3.10, suppose that $F$ is $(1, \ldots, 1)$-homogeneous. Then $F$ is $m$-homogeneous when regarded as a functor from $\mathcal{C}$ to $\mathcal{D}$.

Proof. Combine Propositions 6.1.3.4 and 6.1.3.10.

Corollary 6.1.3.12. Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and a final object, let $\mathcal{D}$ be a differentiable $\infty$-category, and let $F : \mathcal{C}^m \to \mathcal{D}$ be a functor which is $(1, \ldots, 1)$-reduced. Then the composite functor $f : \mathcal{C} \to \mathcal{C}^m \to \mathcal{D}$ is $m$-reduced. If $F$ is multilinear, then $f$ is $m$-homogeneous.

Proof. The first assertion follows by combining Proposition 6.1.3.10 with Remark 6.1.1.30 (note that the diagonal map $\mathcal{C} \to \mathcal{C}^m$ preserves final objects and pushout squares), and the second assertion follows from the first and Proposition 6.1.3.4.

Proof of Proposition 6.1.3.10. We will prove the following:

(*) Let $X \in \mathcal{C}$ and $G : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D}$ be a $(1, \ldots, 1)$-reduced functor. Let $G'$ be the same functor, regarded as a functor of one variable. Then the map $u : G(X) \to (T_{n-1}G')(X)$ factors through a final object of $\mathcal{D}$.

Assuming (*), we can complete the proof as follows. Let $X \in \mathcal{C}$ be an object and let $F'$ be the functor $F$, regarded as a functor of one variable. We wish to show that $(P_{n-1}F')(X)$ is a final object of $\mathcal{D}$. We can write $(P_{n-1}F')(X)$ as the colimit of a sequence

$$F'(X) \xrightarrow{\alpha_1} (T_{n-1}F')(X) \xrightarrow{\alpha_2} (T_{n-1}^2F')(X) \to \cdots.$$ 

Using (*), we deduce that each of the maps $\alpha_k$ factors through a final object of $\mathcal{D}$. Thus $(P_{n-1}F')(X)$ is the colimit of a sequence of final objects of $\mathcal{D}$, and is therefore itself final.

It remains to prove (*). The object $X \in \mathcal{C}$ corresponds to a sequence of objects $\{X_i \in \mathcal{C}_i\}_{1 \leq i \leq m}$. Let $S = \{1, \ldots, m\}$, and consider the functor $Y : N(\mathcal{P}(S)^m) \to \mathcal{D}$ given by the formula

$$Y(S_1, \ldots, S_m) = G(C_{S_1}(X_1), \ldots, C_{S_m}(X_m)).$$

Let $A \subseteq \mathcal{P}(S)^m$ be the collection of all sequences of the form $(S_1, \ldots, S_m)$ where $S_1 = S_2 = \cdots = S_m$ and each $S_i$ is nonempty. Unwinding the definitions, we can identify $u$ with the restriction map

$$G(X) = Y(\emptyset, \ldots, \emptyset) \simeq \lim(Y) \to \lim(Y|N(A)).$$

Let $B$ denote the subset of $\mathcal{P}(S)^m$ consisting of those sequences $(S_1, \ldots, S_m)$ such that $i \in S_i$ for some $i \in \{1, \ldots, m\}$. Then $A \subseteq B$, so $u$ factors as a composition

$$\lim(Y) \to \lim(Y|N(B)) \to \lim(Y|N(A)).$$

We will complete the proof by showing that $\lim(Y|N(B))$ is a final object of $\mathcal{D}$.

Let $B_0 \subseteq B$ be the subset consisting of those sequences $(S_1, \ldots, S_m)$ such that $S_i = \{i\}$ for some $i \in \{1, \ldots, m\}$. We claim that the inclusion $\phi : N(B_0) \hookrightarrow N(B)$ is right cofinal. According to Theorem T.4.1.3.1, it will suffice to show that if $(S_1, \ldots, S_m) \in B$, then the partially ordered set

$$V = \{(S'_1, \ldots, S'_m) \in B_0 : S'_i \subseteq S_i\}$$

is an

has weakly contractible nerve. Let $V_0$ be the subset of $V$ consisting of those sequences $(S'_1, \ldots, S'_m)$ such that $S'_i \subseteq \{i\}$ for all $i$. The inclusion $V_0 \subseteq V$ has a right adjoint, given by the construction

$$(S'_1, \ldots, S'_m) \mapsto (S'_i \cap \{1\}, \ldots, S'_m \cap \{m\})�$$

It follows that the inclusion $N(V_0) \subseteq N(V)$ is a weak homotopy equivalence. It will therefore suffice to show that $N(V_0)$ is weakly contractible. This is clear, since $V_0$ has a final object.

The right cofinality of $\phi$ implies that the restriction map $\lim (Y|N(B)) \to \lim (Y|N(B_0))$ is an equivalence. It will therefore suffice to show that $\lim (Y|N(B_0))$ is a final object of $\overline{D}$. In fact, we claim that $Y(S_1, \ldots, S_m) \in D$ is final whenever $(S_1, \ldots, S_m) \in B_0$. For this, it suffices to observe that one of the sets $S_i$ is a singleton, so that $C_{S_i}(X_i)$ is a final object of $\mathcal{C}$. Then

$$Y(S_1, \ldots, S_m) = G(C_{S_1}(X_1), \ldots, C_{S_m}(X_m))$$

is final by virtue of our assumption that $G$ is $(1, \ldots, 1)$-reduced.

We next establish a partial converse to Proposition 6.1.3.4.

**Proposition 6.1.3.13.** Let $\mathcal{C}_1, \ldots, \mathcal{C}_m$ be $\infty$-categories which admit finite colimits and final objects, let $D$ be an $\infty$-category which admits finite limits, and suppose that $F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to D$ is a functor which is reduced in each variable. Let $\mathcal{C} = \mathcal{C}_1 \times \cdots \times \mathcal{C}_m$ and let $F' = F$, regarded as a functor (of one variable) from $\mathcal{C}$ to $D$. If $F'$ is $m$-excisive, then $F$ is $(1, \ldots, 1)$-excisive.

**Proof.** Without loss of generality, it will suffice to show that $F$ is excisive in its first argument. Suppose we are given objects $\{X_i \in \mathcal{C}_i\}_{2 \leq i \leq n}$ and a pushout square $\sigma$:

$$\begin{array}{ccc}
Y & \longrightarrow & Z \\
\downarrow & & \downarrow \\
Y' & \longrightarrow & Z'
\end{array}$$

in $\mathcal{C}_1$. We wish to show that the diagram $\tau$:

$$\begin{array}{ccc}
F(Y, X_2, \ldots, X_m) & \longrightarrow & F(Z, X_2, \ldots, X_m) \\
\downarrow & & \downarrow \\
F(Y', X_2, \ldots, X_m) & \longrightarrow & F(Z', X_2, \ldots, X_m)
\end{array}$$

is a pullback square in $D$. Let $S = [m] = \{0, \ldots, m\}$. For $2 \leq i \leq m$, choose a morphism $X_i \to *_i$, where $*_i$ is a final object of $\mathcal{C}_i$. These morphisms determine maps of simplicial sets $\Delta^1 \to \mathcal{C}_i$. Taking the product of these maps with $\sigma : \Delta^1 \times \Delta^1 \to \mathcal{C}_1$, we obtain a strongly $\infty$Cartesian $S$-cube

$$U : N(P(S)) \simeq (\Delta^1)^{m+1} \to \mathcal{C}_1 \times \cdots \times \mathcal{C}_m.$$ 

Since $F'$ is $m$-excisive, we deduce that $F(U)$ is a Cartesian $S$-cube in $D$. Our assumption that $F$ is reduced in each variable implies that $F(U)(T)$ is a final object of $D$ unless $T \subseteq \{0, 1\}$. It follows that $F(U)$ is a right Kan extension of its restriction to $N(P(\{0, 1\}))$, so that $\tau = F(U)|N(P(\{0, 1\}))$ is a pullback diagram as desired.

**Corollary 6.1.3.14.** Let $\mathcal{C}_1, \ldots, \mathcal{C}_m$ be $\infty$-categories which admit finite colimits and final objects, let $D$ be a differentiable $\infty$-category, and let $F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to D$ be a functor which is reduced in each variable. Let $\mathcal{C} = \prod_{1 \leq i \leq m} \mathcal{C}_i$, and let $F'$ denote the map $F$, regarded as a functor from $\mathcal{C}$ to $D$. Then there is a canonical equivalence $P_m(F') \simeq P_{1, \ldots, 1}(F)$ (where $P_{1, \ldots, 1}(F)$ is defined as in Proposition 6.1.3.6).
Proof. Since \( P_{1,\ldots,1}(F) \) is \((1,\ldots,1)\)-excisive, it is \(m\)-excisive when viewed as a functor of one variable (Proposition 6.1.3.4). It follows that the canonical map \( F \to P_{1,\ldots,1}(F) \) factors as a composition

\[
F \to P_m(F') \xrightarrow{\alpha} P_{1,\ldots,1}(F),
\]

for some map \( \alpha \) which is uniquely determined up to homotopy.

For \( 1 \leq i \leq m \), let \( \mathcal{E}_i \subseteq \mathcal{C} \) be the full subcategory spanned by those sequences \((X_1,\ldots,X_m)\) where \( X_i \) is a final object of \( \mathcal{C}_i \). The inclusion \( \mathcal{E}_i \subseteq \mathcal{C} \) preserves pushout squares, so that \( (P_m F')|_{\mathcal{E}_i} = P_m(F'|_{\mathcal{E}_i}) \). Since \( F \) is reduced in each variable, \( F'|_{\mathcal{E}_i} \) carries each object of \( \mathcal{E}_i \) to a final object of \( \mathcal{D} \). It follows that \( P_m(F'|_{\mathcal{E}_i}) \) has the same property, so that \( P_m F' \) is reduced in each variable. Invoking Proposition 6.1.3.13, we deduce that \( P_m F' \) is \((1,\ldots,1)\)-excisive, so that the canonical map \( F \to P_m F' \) admits a factorization

\[
F \to P_{1,\ldots,1}(F) \xrightarrow{\beta} P_m(F').
\]

It is easy to see that \( \alpha \) and \( \beta \) are homotopy inverse to one another. \( \square \)

We now describe a procedure for replacing an arbitrary functor \( F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D} \) by a reduced functor.

**Construction 6.1.3.15.** Let \( \mathcal{C}_1,\ldots,\mathcal{C}_m \) be \( \infty \)-categories which admit final objects \( \{*,i \in \mathcal{C}_i\}_{1 \leq i \leq m} \), and let \( \mathcal{D} \) be a pointed \( \infty \)-category which admits finite limits. For \( 1 \leq i \leq m \), let \( U_i : \mathcal{C}_i \to \mathcal{C}_i \) denote the constant functor taking the value \(*_i\), and choose a natural transformation of functors \( \alpha_i : id_{\mathcal{C}_i} \to U_i \). Let \( S = \{1,\ldots,m\} \). For each functor \( F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D} \), consider the functor

\[
F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \times N(\mathcal{P}(S)) \prod_{i \in S} \mathcal{C}_i \to \mathcal{D}
\]

For each \( T \subseteq S \), let \( F^T \) denote the restriction of \( F \) to \( \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \times \{T\} \), so that \( F^T \) is given by the formula \( F^T(X_1,\ldots,X_m) = F(X'_1,\ldots,X'_m) \) where \( X'_i = \begin{cases} X_i & \text{if } i \notin T \\ *_i & \text{if } i \in T. \end{cases} \)

The functor \( F \) determines a natural transformation \( \beta : F = F^0 \to \lim_{\emptyset \neq T \subseteq S} F^T \). We let \( \text{Red}(F) \) denote the fiber of \( \beta \) (in the pointed \( \infty \)-category \( \text{Fun}(\mathcal{C}_1 \times \cdots \times \mathcal{C}_m, \mathcal{D}) \)). We will refer to \( \text{Red}(F) \) as the *reduction* of \( F \).

**Example 6.1.3.16.** In the situation of Construction 6.1.3.15, suppose that \( F \) is constant in its \( i \)th variable, for some \( 1 \leq i \leq m \). Then \( \text{Red}(F) \) carries each object of \( \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \) to a final object of \( \mathcal{D} \).

**Proposition 6.1.3.17.** Let \( F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D} \) be a functor between \( \infty \)-categories. Assume that each \( \mathcal{C}_i \) has a final object and that \( \mathcal{D} \) is pointed and admits finite limits. Then:

(a) The functor \( \text{Red}(F) : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D} \) is reduced.

(b) Let \( G : \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{D} \) be any reduced functor. Then the canonical map \( \text{Red}(F) \to F \) induces a homotopy equivalence

\[
\text{Map}_{\text{Fun}}(\mathcal{C}_1 \times \cdots \times \mathcal{C}_m, \mathcal{D})(G, \text{red}(F)) \to \text{Map}_{\text{Fun}}(\mathcal{C}_1 \times \cdots \times \mathcal{C}_m, \mathcal{D})(G, F).
\]

**Proof.** We first prove (a). For \( T \subseteq S = \{1,\ldots,m\} \), let \( F^T \) be defined as in Construction 6.1.3.15. Suppose we are given objects \( \{X_i \in \mathcal{C}_i\}_{1 \leq i \leq m} \) such that some \( X_j \) is a final object of \( \mathcal{C}_j \). Then for \( T \subseteq S \), the canonical map \( F^T(X_1,\ldots,X_m) \to F^{T \cup \{j\}}(X_1,\ldots,X_m) \) is an equivalence. It follows that the diagram \( \{F^T(X_1,\ldots,X_m)\}_{\emptyset \neq T \subseteq S} \) is a right Kan extension of \( \{F^T(X_1,\ldots,X_m)\}_{\emptyset \neq T \subseteq S} \), so that the canonical map

\[
\lim_{\emptyset \neq T \subseteq S} F^T(X_1,\ldots,X_m) \to F^{\{j\}}(X_1,\ldots,X_m)
\]
is an equivalence. Consequently, \( \text{Red}(F)(X_1, \ldots, X_m) \) is given by the fiber of the map
\[
F^0(X_1, \ldots, X_m) \to F^{(j)}(X_1, \ldots, X_m).
\]
Since this map is an equivalence, we deduce that \( \text{Red}(F)(X_1, \ldots, X_m) \) is a final object of \( \mathcal{D} \).

We now prove (b). We have a fiber sequence of spaces
\[
\text{Map}_{\text{Fun}(\mathcal{C} \times \mathcal{D})}(G, \text{Red}(F)) \to \text{Map}_{\text{Fun}(\mathcal{C} \times \mathcal{D})}(G, F) \to \lim_{\emptyset \neq T \subseteq S} \text{Map}_{\text{Fun}(\mathcal{C} \times \mathcal{D})}(G, F^T).
\]
It will therefore suffice to show that the mapping space \( \text{Map}_{\text{Fun}(\mathcal{C} \times \mathcal{D})}(G, F^T) \) is contractible for every nonempty subset \( T \subseteq S \). Choose an element \( j \in T \), and let \( \mathcal{E} \subseteq \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \) be the full subcategory spanned by those objects \( (X_1, \ldots, X_m) \) for which \( X_j \) is a final object. Note that \( F^T \) is a right Kan extension of \( F^j|\mathcal{E} \), so the restriction map \( \text{Map}_{\text{Fun}(\mathcal{C} \times \mathcal{D})}(G, F^T) \to \text{Map}_{\text{Fun}(\mathcal{E}, \mathcal{D})}(G|\mathcal{E}, F^j|\mathcal{E}) \) is a homotopy equivalence. It will therefore suffice to show that \( \text{Map}_{\text{Fun}(\mathcal{E}, \mathcal{D})}(G|\mathcal{E}, F^j|\mathcal{E}) \) is contractible. In fact, we claim that \( G|\mathcal{E} \) is an initial object of \( \text{Fun}(\mathcal{E}, \mathcal{D}) \). This follows immediately from our assumption that \( G \) is reduced (since the \( \infty \)-category \( \mathcal{D} \) is assumed to be pointed).

**Corollary 6.1.3.18.** Let \( \mathcal{C}_1, \ldots, \mathcal{C}_m \) be \( \infty \)-categories which admit final objects, let \( \mathcal{D} \) be a pointed \( \infty \)-category which admits finite limits, and let \( \text{Fun}_* (\mathcal{C}_1 \times \cdots \times \mathcal{C}_m, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\mathcal{C}_1 \times \cdots \times \mathcal{C}_m, \mathcal{D}) \) spanned by the reduced functors. Then the inclusion
\[
\text{Fun}_* (\mathcal{C}_1 \times \cdots \times \mathcal{C}_m, \mathcal{D}) \to \text{Fun}(\mathcal{C}_1 \times \cdots \times \mathcal{C}_m, \mathcal{D})
\]
adopts a right adjoint, given by the construction \( F \mapsto \text{Red}(F) \).

**Remark 6.1.3.19.** Let \( \mathcal{C}_1, \ldots, \mathcal{C}_m \) be \( \infty \)-categories which admit finite colimits and final object, let \( \mathcal{C} = \prod_{1 \leq i \leq m} \mathcal{C}_m \), and let \( \mathcal{D} \) be a pointed differentiable \( \infty \)-category. Since the localization functors
\[
P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D})
\]
are left exact, we have a canonical equivalence
\[
P_n(\text{Red}(F)) \simeq \text{Red}(P_nF)
\]
for every functor \( F : \mathcal{C} \to \mathcal{D} \). In the case \( n = m \), we can identify the left hand side with \( P_1 \cdots 1(\text{Red}(F)) \) (Corollary 6.1.3.14) and thereby obtain an equivalence \( P_{1 \cdots 1}(\text{Red}(F)) \simeq \text{Red}(P_nF) \).

**Construction 6.1.3.20.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and a final object, and let \( \mathcal{D} \) be a pointed \( \infty \)-category which admits finite limits. Consider the functor \( q : \mathcal{C}^n \to \mathcal{C} \), given by the formula
\[
(X_1, \ldots, X_n) \mapsto \prod_{1 \leq i \leq n} X_i.
\]
For every functor \( F : \mathcal{C} \to \mathcal{D} \), we let \( \text{cr}_n(F) = \text{Red}(F \circ q) \) denote the reduction of the functor
\[
(X_1, \ldots, X_n) \mapsto F(X_1 \amalg \cdots \amalg X_n).
\]
We will refer to \( \text{cr}_n(F) \) as the \( n \)th cross effect of \( F \).

**Variant 6.1.3.21.** Suppose we are given a finite collection of \( \infty \)-categories \( \{ \mathcal{C}_s \}_{s \in S} \) which admit finite colimits and final objects and a collection of nonnegative integers \( n_s = \{ n_s \}_{s \in S} \). Let \( \mathcal{C} = \prod_{s \in S} \mathcal{C}_s \) and let \( \mathcal{D} \) be a pointed \( \infty \)-category which admits finite limits. The product of the maps \( q_s : \mathcal{C}^{n_s} \to \mathcal{C}_s \) of Construction 6.1.3.20 gives a map \( q : \prod_{s \in S} \mathcal{C}_s \to \mathcal{C} \). We define \( \text{cr}_n(F) = \text{Red}(F \circ q) \). When \( S \) has a single element, this reduces to the cross effect appearing in Construction 6.1.3.20. When each of the integers \( n_s \) is equal to 1, it reproduces the reduction functor of Construction 6.1.3.15.
**Proposition 6.1.3.22.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and a final object, let $\mathcal{D}$ be a pointed differentiable $\infty$-category, and let $F : \mathcal{C} \to \mathcal{D}$ be an n-excisive functor. For each $m \leq n + 1$, the cross-effect $cr_m(F) : \mathcal{C}^m \to \mathcal{D}$ is $(n - m + 1, \ldots, n - m + 1)$-excisive.

**Proof.** The proof proceeds by induction on $m$. When $m = 0$ it is vacuous. When $m = 1$, $cr_1(F)$ is given by the fiber of a natural transformation $F \to F_0$, where $F_0$ is a constant functor. Since $F$ and $F_0$ are both $n$-excisive, we conclude that $cr_1(F)$ is $n$-excisive. Let us therefore assume that $m \geq 2$. Fix objects $X_1, X_2, \ldots, X_m \in \mathcal{C}$; we will show that the functor

$$X_1 \mapsto cr_m(F)(X_1, \ldots, X_m)$$

is $(n - m + 1)$-excisive. Let $\ast$ denote a final object of $\mathcal{C}$. Let $G, G' : \mathcal{C} \to \mathcal{D}$ be defined by the formulas

$$G(X) = G(X \amalg X_m) \quad G'(X) = F(X \amalg \ast).$$

Let $G'$ be the fiber of the natural transformation $G \to G'$ induced by the map $X_m \to \ast$. Unwinding the definitions, we obtain an equivalence

$$cr_m(F)(X_1, \ldots, X_m) \simeq cr_{m-1}(G')(X_1, \ldots, X_{m-1}).$$

It will therefore suffice to show that $cr_{m-1}(G')$ is $(n - m + 1, \ldots, n - m + 1)$-excisive. Using the inductive hypothesis, we are reduced to proving that $G'$ is $(n - 1)$-excisive. Let $S = [n - 1] = \{0, \ldots, n - 1\}$ and let $Y : N(\mathcal{P}(S)) \to \mathcal{C}$ be a strongly coCartesian $S$-cube. Let $S_+ = S \cup \{n\}$ and define a functor $Y_+ : N(\mathcal{P}(S_+)) \to \mathcal{C}$ by the formula

$$Y_+(T) = \begin{cases} Y(T) \amalg X_m & \text{if } n \notin T \\ Y(T) \amalg \ast & \text{if } n \in T. \end{cases}$$

We observe that $Y_+$ is a strongly coCartesian $S_+$-cube in $\mathcal{C}$. Since $F$ is $n$-excisive, $F(Y_+)$ is a Cartesian $S_+$-cube in $\mathcal{D}$. It follows that the diagram

$$\begin{array}{ccc} F(Y(\emptyset) \amalg X_m) & \longrightarrow & \lim_{\emptyset \neq T \subseteq S} F(Y(T) \amalg X_m) \\ \downarrow & & \downarrow \\ F(Y(\emptyset) \amalg \ast) & \longrightarrow & \lim_{\emptyset \neq T \subseteq S} F(Y(T) \amalg \ast) \end{array}$$

is a pullback square. Taking fibers in the vertical direction, we deduce that $G'(Y)$ is a Cartesian $S$-cube in $\mathcal{D}$. \hfill $\Box$

**Remark 6.1.3.23.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and a final object, $\mathcal{D}$ a pointed differentiable $\infty$-category, and $F : \mathcal{C} \to \mathcal{D}$ a functor. Combining Remarks 6.1.3.19 and 6.1.3.30, we obtain a canonical equivalence

$$P_{1, \ldots, 1} cr_n(F) \simeq cr_n(P_n(F)).$$

It follows from Proposition 6.1.3.22 that the functor $cr_n(P_{n-1}F)$ is a final object of $\text{Fun}(\mathcal{C}^n, \mathcal{D})$. Since the functor $cr_n$ is left exact, we obtain an equivalence $cr_n(D_n(F)) \simeq cr_n P_n(F)$, where $D_n(F) = \text{fib}(P_n(F) \to P_{n-1}(F))$. We therefore obtain an equivalence of functors

$$cr_n(D_n(F)) \simeq P_{1, \ldots, 1} cr_n(F).$$

**Proposition 6.1.3.24.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ be a pointed differentiable $\infty$-category, let $n \geq 1$ be an integer, and let $F : \mathcal{C} \to \mathcal{D}$ be a functor. Then $F$ is $n$-reduced if and only if it satisfies the following conditions:
6.1. THE CALCULUS OF FUNCTORS

(1) The functor $F$ is 1-reduced: that is, it carries final objects of $\mathcal{C}$ to final objects of $\mathcal{D}$.

(2) For every positive integer $m < n$, the functor $P_{1,\ldots,1} \Phi_m(F)$ carries each object of $\mathcal{C}^m$ to a final object of $\mathcal{D}$.

Proof. If $F$ is $n$-reduced, then assertion (1) is obvious and assertion (2) follows from Remark 6.1.3.23. Conversely, suppose that $F$ satisfies (1) and (2). We will prove that $F$ is $k$-reduced for $1 \leq k \leq n$. The proof proceeds by induction on $k$. When $k = 1$ the desired result follows from (1). To carry out the inductive step, it suffices to show that if $F$ is $m$-reduced and $P_{1,\ldots,1} \Phi_m F$ is trivial, then $F$ is $(m + 1)$-reduced. This follows immediately from Remark 6.1.3.23.

6.1.4 Symmetric Functors

Let $F : \mathcal{C} \to \mathcal{D}$ be a functor, where $\mathcal{C}$ is an $\infty$-category which admits finite colimits and a final object and $\mathcal{D}$ is a pointed differentiable $\infty$-category. In §6.1.2 we defined the the Taylor tower

$$\cdots \to P_3 F \to P_2 F \to P_1 F \to P_0 F.$$  

In good cases, this affords a representation of $F$ as a successive extension of homogeneous functors $D_n F = \text{fib}(P_n F \to P_{n-1} F)$, each of which is an $n$-homogeneous functor from $\mathcal{C}$ to $\mathcal{D}$. In this section, we will continue the analysis by providing a classification of $n$-homogeneous functors.

Let us begin with a bit of motivation from linear algebra. Let $V$ be a finite-dimensional vector space over the real numbers, and let $q : V \to \mathbb{R}$ be a quadratic form (that is, a map given by a homogeneous polynomial of degree 2). Then $q$ determines a symmetric bilinear form $b : V \times V \to \mathbb{R}$, given by the formula

$$b(v, w) = q(v + w) - q(v) - q(w).$$

We will refer to $b$ as the polarization of $q$. Conversely, any symmetric bilinear form $b : V \times V \to \mathbb{R}$ determines a quadratic form $q : V \to \mathbb{R}$, given by the formula $q(v) = \frac{1}{2} b(v, v)$. These two constructions are inverse to one another, and establish a bijective correspondence between symmetric bilinear forms on $V$ and quadratic forms on $V$. In this section, we will establish an analogous correspondence in the setting of the calculus of functors. Suppose that $Q : \mathcal{C} \to \mathcal{D}$ is a 2-homogeneous functor. The analogue of the polarization in this context is the 2-fold cross-effect $\Phi_2(F) : \mathcal{C} \times \mathcal{C} \to \mathcal{D}$ (see Construction 6.1.3.20). Using Proposition 6.1.3.22, we see that $\Phi_2(F)$ is reduced and excisive in each variable: that is, it can be regarded as the analogue of a bilinear form. It is not difficult to see that $\Phi_2(F)$ is symmetric in its two arguments. Our main goal is to show that $F$ can be functorially recovered from $\Phi_2(F)$. To carry out this recovery, we need to take into account the fact that $\Phi_2(F)$ is a symmetric bifunctor: that is, we have a canonical equivalence $\Phi_2(F)(X, Y) \simeq \Phi_2(F)(Y, X)$ for $X, Y \in \mathcal{C}$. We begin by introducing some terminology for a more systematic treatment of symmetry.

Notation 6.1.4.1. For every group $G$, we let $EG$ denote the simplicial set given by the Čech nerve of the map $G \to *$ (so that the set of $m$-simplices of $EG$ is given by $G^{m+1}$, for each $m \geq 0$). Then $EG$ is a contractible Kan complex with a free action of the group $G$. We let $BG$ denote the quotient $EG/G$. We refer to $BG$ as the classifying space of $G$.

Let $n \geq 0$ be an integer and let $\Sigma_n$ be the symmetric group on $n$ letters. For every simplicial set $K$, we let $K^{(n)}$ denote the quotient $(K^n \times E\Sigma_n)/\Sigma_n$. We refer to $K^{(n)}$ as the $n$th extended power of $K$. If $K$ is an $\infty$-category, then $K^{(n)}$ is also an $\infty$-category, and is a model for the $\infty$-category $\text{Sym}^n(K)$ given by the homotopy quotient for the action of $\Sigma_n$ acting on $K^n$.

Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. A symmetric $n$-ary functor from $\mathcal{C}$ to $\mathcal{D}$ is a functor $F : \mathcal{C}^{(n)} \to \mathcal{D}$. In this case, $F$ determines a functor $\mathcal{C}^n \to \mathcal{D}$, which is invariant up to (coherent) homotopy under permutation of its arguments. We let $\text{SymFun}^n(\mathcal{C}, \mathcal{D})$ denote the $\infty$-category $\text{Fun}(\mathcal{C}^{(n)}, \mathcal{D})$ of symmetric $n$-ary functors from $\mathcal{C}$ to $\mathcal{D}$. If $\mathcal{C}$ and $\mathcal{D}$ admit final objects, we say that a symmetric $n$-ary functor $F : \mathcal{C}^{(n)} \to \mathcal{D}$ is reduced if the underlying functor $\mathcal{C}^n \to \mathcal{D}$ is reduced (in each variable). We let $\text{SymFun}^n_{\ast}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{SymFun}^n(\mathcal{C}, \mathcal{D})$ spanned by the reduced symmetric $n$-ary functors.
Example 6.1.4.2. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category, which we can regard as a commutative monoid object of $\mathcal{C}_{\infty}$. The symmetric monoidal structure determines a symmetric $n$-ary functor

$$\mathcal{C}^{(n)} \simeq \text{Sym}^n(\mathcal{C}) \to \mathcal{C},$$

whose underlying map $\mathcal{C}^n \to \mathcal{C}$ is given by $(X_1, \ldots, X_n) \mapsto X_1 \otimes \cdots \otimes X_n$.

If $\mathcal{C}$ is an $\infty$-category which admits finite coproducts, then we can regard $\mathcal{C}$ as endowed with the coCartesian symmetric monoidal structure of §2.4.3. We therefore obtain a symmetric $n$-ary functor $\coprod: \mathcal{C}^{(n)} \to \mathcal{C}$, whose underlying map $\mathcal{C}^n \to \mathcal{C}$ carries a sequence of objects $(X_1, \ldots, X_n)$ to the coproduct $\coprod_{1 \leq i \leq n} X_i$.

Our first goal is to show that for any functor $F: \mathcal{C} \to \mathcal{D}$, the cross-effect $cr_n(F)$ has the structure of a symmetric $n$-ary functor.

Proposition 6.1.4.3. Let $\mathcal{C}$ be an $\infty$-category with a final object and let $\mathcal{D}$ be a pointed $\infty$-category which admits finite limits. Then the inclusion $i: \text{SymFun}^n(\mathcal{C}, \mathcal{D}) \hookrightarrow \text{SymFun}^n(\mathcal{C}, \mathcal{D})$ admits a right adjoint.

Proof. Consider the inclusion map $j: \text{Fun}_*(\mathcal{C}^n, \mathcal{D}) \to \text{Fun}(\mathcal{C}^n, \mathcal{D})$ (here $\text{Fun}_*(\mathcal{C}^n, \mathcal{D})$ denotes the full subcategory of $\text{Fun}(\mathcal{C}^n, \mathcal{D})$ spanned by those functors which are reduced in each variable). The $\infty$-category $\text{Fun}(\mathcal{C}^n, \mathcal{D})$ carries an action of the symmetric group $\Sigma_n$ which preserves the image of $j$, and $i$ is the map induced by $j$ by taking homotopy invariants with respect to this action. Since the functor $j$ has a right adjoint (Corollary 6.1.3.18), we conclude that $i$ has a right adjoint.

Remark 6.1.4.4. The proof of Proposition 6.1.4.3 gives a bit more information: namely, it shows that the right adjoint $\text{SymFun}^n(\mathcal{C}, \mathcal{D}) \to \text{SymFun}^n(\mathcal{C}, \mathcal{D})$ to $i$ fits into a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\text{SymFun}^n(\mathcal{C}, \mathcal{D}) & \xrightarrow{\theta} & \text{SymFun}^n(\mathcal{C}, \mathcal{D}) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathcal{C}^n, \mathcal{D}) & \xrightarrow{\text{Red}} & \text{Fun}_*(\mathcal{C}^n, \mathcal{D}),
\end{array}
$$

where the functor $\text{Red}$ is as defined in Construction 6.1.3.15. We will abuse notation by denoting the induced functor $\text{SymFun}^n(\mathcal{C}, \mathcal{D}) \to \text{SymFun}^n(\mathcal{C}, \mathcal{D})$ also by $\text{Red}$. If $F: \mathcal{C}^n \to \mathcal{D}$ is a symmetric $n$-ary functor, we will refer to $\text{Red}(F)$ as the reduction of $F$.

Construction 6.1.4.5. Let $F: \mathcal{C} \to \mathcal{D}$ be a functor between $\infty$-categories. Assume that $\mathcal{C}$ has finite coproducts and a final object, and that $\mathcal{D}$ is pointed and admits finite limits. Let $\coprod: \mathcal{C}^{(n)} \to \mathcal{C}$ be as in Example 6.1.4.2, so that the composition

$$\mathcal{C}^{(n)} \coprod \mathcal{C} \xrightarrow{F} \mathcal{D}$$

is a symmetric $n$-ary functor from $\mathcal{C}$ to $\mathcal{D}$. We let $\text{cr}_{n}(F) \in \text{SymFun}^n(\mathcal{C}, \mathcal{D})$ denote the reduction of $F \circ \coprod$. We will refer to $\text{cr}_{n}(F)$ as the symmetric cross-effect of $F$.

Remark 6.1.4.6. In the situation of Construction 6.1.4.5, the symmetric cross effect $\text{cr}_{n}(F)$ induces a map $\mathcal{C}^{n} \to \mathcal{D}$, which can be identified with the cross effect $\text{cr}_{n}(F)$ of Construction 6.1.3.20 (see Remark 6.1.4.4).

We can now state the main result of this section.

Theorem 6.1.4.7. Let $\mathcal{C}$ be a pointed $\infty$-category which admits finite colimits and let $\mathcal{D}$ be a pointed differentiable $\infty$-category. Then the formation of symmetric cross-effects induces a fully faithful embedding

$$\text{cr}_{n}: \text{Homog}^n(\mathcal{C}, \mathcal{D}) \to \text{SymFun}^n(\mathcal{C}, \mathcal{D}).$$

The essential image of $\text{cr}_{n}$ is the full subcategory $\text{SymFun}^n_{\text{lin}}(\mathcal{C}, \mathcal{D}) \subseteq \text{SymFun}^n(\mathcal{C}, \mathcal{D})$ spanned by those symmetric $n$-ary functors $E: \mathcal{C}^{(n)} \to \mathcal{D}$ such that the underlying functor $\mathcal{C}^{n} \to \mathcal{D}$ is multilinear.
6.1. THE CALCULUS OF FUNCTORS

We will give the proof of Theorem 6.1.4.7 at the end of this section. The main idea is to use Corollary 6.1.2.9 to reduce to the case where \( \mathcal{D} \) is a stable \( \infty \)-category, in which case we can explicitly construct a homotopy inverse to the functor \( \mathfrak{c}_r(n) \). To carry out this strategy, we will need some preliminary results.

**Lemma 6.1.4.8.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, let \( \mathcal{D} \) be an \( \infty \)-category which admits finite limits, and let \( F : \mathcal{C} \to \mathcal{D} \) be a \( n \)-excisive functor for \( n \geq 1 \). The following conditions are equivalent:

1. The functor \( F \) is \((n-1)\)-excisive.
2. Let \( S = \{1, \ldots, n\} \). For every strongly coCartesian \( S \)-cube \( X : N(\mathcal{P}(S)) \to \mathcal{C} \) such that \( X(\emptyset) \) is a final object of \( \mathcal{C} \), \( F(X) \) is a Cartesian \( S \)-cube of \( \mathcal{D} \).

**Proof.** The implication (1) \( \Rightarrow \) (2) is obvious. Suppose that (2) is satisfied. Let \( S = \{1, \ldots, n\} \) and let \( X : N(\mathcal{P}(S)) \to \mathcal{C} \) be a strongly coCartesian \( S \)-cube. Let \( S_+ = S \cup \{0\} \) and choose a strongly coCartesian \( S_+ \)-cube \( X_+ : N(\mathcal{P}(S_+)) \to \mathcal{C} \) extending \( S \) such that \( X_+ (\{0\}) \) is a final object \( * \in \mathcal{C} \). Since \( F \) is \( n \)-excisive, \( F(X_+) \) is a Cartesian \( S_+ \) cube in \( \mathcal{D} \) so we have a pullback square

\[
\begin{array}{ccc}
F(X(\emptyset)) & \longrightarrow & \lim_{\emptyset \neq T \subseteq S} F(X(T)) \\
\downarrow & & \downarrow \\
F(*) & \longrightarrow & \lim_{\emptyset \neq T \subseteq S} F(X(T \cup \{0\})).
\end{array}
\]

Using condition (2) and Proposition 6.1.1.13, we deduce that the lower horizontal map is an equivalence. It follows that the upper horizontal map is an equivalence, so that \( F(X) \) is a Cartesian \( S \)-cube in \( \mathcal{D} \).

**Lemma 6.1.4.9.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object *, let \( \mathcal{D} \) be a stable \( \infty \)-category, and let \( F : \mathcal{C} \to \mathcal{D} \) be an \( n \)-excisive functor. Let \( \prod : \mathcal{C}^n \to \mathcal{C} \) be the functor given by \( (C_1, \ldots, C_n) \mapsto \prod_{1 \leq i \leq n} C_i \). The following conditions are equivalent:

1. The functor \( F \) is \( n \)-excisive.
2. For every finite sequence of morphisms \( * \to C_i \) \( 1 \leq i \leq n \) in \( \mathcal{C} \) (given by maps \( \alpha_i : \Delta^1 \to \mathcal{C} \)), let \( S = \{1, \ldots, n\} \) and let \( X : N(\mathcal{P}(S)) \to \mathcal{C} \) be the \( S \)-cube given by the composition

\[
N(\mathcal{P}(S)) \simeq (\Delta^1)^n \prod_{i=1}^n \mathcal{C}.
\]

Then \( F(X) \) is a Cartesian \( S \)-cube in \( \mathcal{D} \).

**Proof.** The implication (1) \( \Rightarrow \) (2) is obvious. Assume that (2) is satisfied. We will show that \( F \) satisfies the criterion of Lemma 6.1.4.8. To this end, let \( S = \{1, \ldots, n\} \) and let \( Y : N(\mathcal{P}(S)) \to \mathcal{C} \) be a coCartesian \( S \)-cube in \( \mathcal{C} \) with \( Y(\emptyset) = * \). We wish to prove that \( F(Y) \) is a Cartesian \( S \)-cube in \( \mathcal{D} \). For \( 1 \leq i \leq n \), let \( C_i = Y(\{i\}) \), so that \( Y \) determines a map \( * \to C_i \). Let \( X \) be the \( S \)-cube defined in (2). Then there is an evident natural transformation of \( S \)-cubes \( \alpha : X \to Y \), which we can identify with a strongly coCartesian \( S_+ \)-cube in \( \mathcal{C} \) for \( S_+ = \{0, \ldots, n\} \). Since \( F \) is \( n \)-excisive, we have a pullback diagram

\[
\begin{array}{ccc}
F(X(\emptyset)) & \longrightarrow & \lim_{\emptyset \neq T \subseteq S} F(X(T)) \\
\downarrow & & \downarrow \\
F(Y(\emptyset)) & \longrightarrow & \lim_{\emptyset \neq T \subseteq S} F(Y(T)).
\end{array}
\]

Assumption (2) implies that the upper horizontal map is an equivalence. Since \( \mathcal{D} \) is stable, this implies that the lower horizontal horizontal map is also an equivalence: that is, \( F(Y) \) is a Cartesian \( S \)-cube in \( \mathcal{D} \).
Proposition 6.1.4.10. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, and let \( \mathcal{D} \) be a stable \( \infty \)-category. Suppose that \( F : \mathcal{C} \to \mathcal{D} \) is an \( n \)-excisive functor for some \( n \geq 1 \). The following conditions are equivalent:

(a) The functor \( F \) is \((n-1)\)-excisive.

(b) The \( n \)-fold cross-effect \( \text{cr}_n(F) \) carries each object of \( \mathcal{C}^n \) to a zero object of \( \mathcal{D} \).

Proof. If \( F \) is \((n-1)\)-excisive, then Proposition 6.1.3.22 implies that \( \text{cr}_n(F) \) is \((0,0,\ldots,0)\)-excisive: that is, constant. Since \( \text{cr}_n(F) \) is reduced (and \( n > 0 \)) we conclude that \((a) \Rightarrow (b)\). Conversely, suppose that \((b)\) is satisfied. We will prove that \( F \) is \((n-1)\)-excisive by showing that it satisfies the second condition of Lemma 6.1.4.9. Let \( * \) be a final object of \( \mathcal{C} \) and suppose we are given a finite collection of morphisms \( \{ \alpha_i : * \to C_i \}_{1 \leq i \leq n} \). Let \( S = \{1, \ldots, n\} \) and let \( X : \mathcal{N}(\mathcal{P}(S)) \to \mathcal{C} \) be the strongly coCartesian \( S \)-cube defined in part (2) of Lemma 6.1.4.9. We wish to prove that \( F(X) \) is a Cartesian \( S \)-cube in \( \mathcal{D} \).

For \( 1 \leq i \leq n \), extend \( \alpha_i \) to a 2-simplex \( \sigma_i : C_i \to S \):

\[
\begin{array}{ccc}
C_i & \xrightarrow{\alpha_i} & S \\
\downarrow & & \downarrow \\
* & \xrightarrow{id} & * 
\end{array}
\]

in \( \mathcal{C} \). Let \( \prod : \mathcal{C}^S \to \mathcal{C} \) be the functor given by the formula

\[
(K_1, \ldots, K_n) \mapsto \prod_{1 \leq i \leq n} K_i,
\]

and let \( Y : (\Delta^2)^S \to \mathcal{C} \) denote the composition

\[
(\Delta^2)^S \prod_{\sigma_i} \mathcal{C}^S \to \mathcal{C}.
\]

For \( 0 \leq i \leq n \), let \( Y_i : \mathcal{N}(\mathcal{P}(S)) \to \mathcal{C} \) be defined by the formula \( Y_i(T) = Y(a_1, \ldots, a_n) \), where

\[
a_j = \begin{cases} 
0 & \text{if } j \geq i \text{ and } j \notin T \\
2 & \text{if } j < i \text{ and } j \in T \\
1 & \text{otherwise.}
\end{cases}
\]

Note that \( Y_n \) is equivalent to the \( S \)-cube \( X \). Consequently, to complete the proof it will suffice to show that each \( F(Y_i) \) is a Cartesian \( S \)-cube in \( \mathcal{D} \). The proof proceeds by induction on \( i \). When \( i = 0 \), we must show that the canonical map

\[
u : F(Y_0(\emptyset)) \to \lim_{\emptyset \neq T \subseteq S} F(Y_0(T))
\]

is an equivalence. Unwinding the definitions, we see that the fiber of \( \nu \) is given by \( \text{cr}_n(F)(X_1, \ldots, X_n) \), which vanishes by (2).

Now suppose that \( i > 0 \), and let \( S' = S - \{i\} \). We have a commutative diagram

\[
\begin{array}{cccc}
F(Y_i(\emptyset)) & \to & F(Y_{i-1}(\emptyset)) & \to & F(Y_{i-1}(\{i\})) \\
\downarrow & & \downarrow & & \downarrow \\
\lim_{\emptyset \neq T \subseteq S'} F(Y_i(T)) & \to & \lim_{\emptyset \neq T \subseteq S'} F(Y_{i-1}(T)) & \to & \lim_{\emptyset \neq T \subseteq S'} F(Y_{i-1}(T \cup \{i\})).
\end{array}
\]

We wish to prove that the left square is a pullback diagram (note that \( Y_{i-1}(T) = Y_i(T \cup \{i\}) \) for \( T \subseteq S' \)). To prove this, we observe that the right square is a pullback diagram by the inductive hypothesis, and the outer rectangle is a pullback square because the horizontal compositions are equivalences.
Corollary 6.1.4.11. Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite colimits, and let \( \mathcal{D} \) be a stable \( \infty \)-category which admits countable colimits. Let \( \alpha : F \to G \) be a natural transformation between \( n \)-homogeneous functors \( F, G : \mathcal{C} \to \mathcal{D} \). Then \( \alpha \) is an equivalence if and only if the induced map \( \text{cr}_n(F) \to \text{cr}_n(G) \) is an equivalence.

Proof. Suppose \( \text{cr}_n(\alpha) \) is an equivalence. Let \( H \) be the fiber of \( \alpha \). Note that \( H \) is \( n \)-homogeneous and that \( \text{cr}_n(H) \cong \text{fib}(\text{cr}_n(\alpha)) \) is a final object of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \). Using Proposition 6.1.4.10, we deduce that \( H \) is \((n-1)\)-excisive. Since \( H \) is \( n \)-reduced, we conclude that \( H \) is a zero object of the stable \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{D}) \), so that \( \alpha \) is an equivalence.

Lemma 6.1.4.12. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits, let \( \mathcal{D} \) be a stable \( \infty \)-category, and let \( F : \mathcal{C} \to \mathcal{D} \) be a 1-excisive functor. Then \( F \) carries strongly coCartesian cubes in \( \mathcal{C} \) to strongly coCartesian cubes in \( \mathcal{D} \).

Proof. This follows immediately from the characterization of strongly coCartesian cubes given in Proposition 6.1.1.15.

Proposition 6.1.4.13. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, and let \( \mathcal{D} \) be a stable \( \infty \)-category. Let \( F : \mathcal{C}^n \to \mathcal{D} \) be a functor, and for every permutation \( \sigma \) in the symmetric group \( \Sigma_n \), let \( F^\sigma : \mathcal{C}^n \to \mathcal{D} \) be the composition of \( F \) with the isomorphism \( \mathcal{C}^n \to \mathcal{C}^n \) obtained by applying the permutation \( \sigma \). Let \( \delta : \mathcal{C} \to \mathcal{C}^n \) be the diagonal map and let \( f = F \circ \delta \), so that \( f = F^\sigma \circ \delta \) for every permutation \( \sigma \). Suppose that \( F \) is \((1, \ldots, 1)\)-excisive. Then there is a canonical equivalence

\[
\text{cr}_n(f) \cong \bigoplus_{\sigma \in \Sigma_n} \text{Red}(F^\sigma).
\]

In particular, if \( F \) is \((1, \ldots, 1)\)-homogeneous, then \( \text{cr}_n(f) \cong \bigoplus_{\sigma \in \Sigma_n} F^\sigma \).

Proof. Let \( S = \{1, \ldots, n\} \). Choose an initial object \( \emptyset \in \mathcal{C} \). For every finite sequence of subsets \( \vec{T} = (T_1, T_2, \ldots, T_n) \in \mathcal{P}(S)^n \), define \( U_{\vec{T}} : \mathcal{C}^n \to \mathcal{C}^n \) by the formula

\[
U_{\vec{T}}(X_1, \ldots, X_n) = (\prod_{i \in T_1} X_i, \ldots, \prod_{i \in T_n} X_i)
\]

and let \( F_{\vec{T}} = F \circ U_{\vec{T}} \). By construction, \( \text{cr}_n(f) \) is the reduction of the functor \( F_{(S, \ldots, S)} \).

For any sequence of objects \( X_1, \ldots, X_n \in \mathcal{C} \), our assumption that \( F \) is \((1, \ldots, 1)\)-excisive implies that the construction \( \vec{T} \mapsto F_{\vec{T}}(X_1, \ldots, X_n) \) is a strongly coCartesian separately in each variable (Lemma 6.1.4.12). It follows that the canonical map

\[
\lim_{\vec{T} \in \mathcal{P}(S)^n} F_{\vec{T}} \to F_{(S, \ldots, S)}
\]

is an equivalence, so that \( \text{cr}_n(f) \) can be identified with the colimit of the diagram \( Z : \mathcal{N}(\mathcal{P}_{\leq 1}(S)^n) \to \text{Fun}(\mathcal{C}^n, \mathcal{D}) \) given by \( Z(\vec{T}) = \text{Red}(F_{\vec{T}}) \).

Let \( P \subseteq \mathcal{P}_{\leq 1}(S)^n \) be the subset consisting of those sequences \( \vec{T} = (T_1, \ldots, T_n) \) with \( \bigcup_i T_i = S \). Note that if \( \bigcup_i T_i \neq S \), then the functor \( F_{\vec{T}} \) is independent of one of its arguments and therefore \( \text{Red}(F_{\vec{T}}) \cong 0 \) (Example 6.1.3.16). It follows that the diagram \( Z \) is a left Kan extension of \( Z|\mathcal{N}(P) \). Moreover, \( \mathcal{N}(P) \) is a discrete partially ordered set, whose elements can be identified with permutations of \( S \). The desired result now follows from the observation that if \( \vec{T} \) corresponds to a permutation \( \sigma \in \Sigma_n \), then \( F_{\vec{T}} \cong F^\sigma \).

Proof of Theorem 6.1.4.7. We first show that the essential image of \( \text{cr}_{(n)} \) is contained in \( \text{SymFun}^n_{\text{lin}}(\mathcal{C}, \mathcal{D}) \). In view of Remark 6.1.4.6, it will suffice to show that if \( F : \mathcal{C} \to \mathcal{D} \) is \( n \)-homogeneous, then \( \text{cr}_n(F) \) is \((1, \ldots, 1)\)-homogeneous. The functor \( \text{cr}_n(F) \) is \((1, \ldots, 1)\)-reduced by Proposition 6.1.3.17 and \((1, \ldots, 1)\)-excisive by Proposition 6.1.3.22.
We have a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
\text{Hom}^n(\mathcal{C}, \text{Sp}(\mathcal{D})) & \xrightarrow{\text{cr}(n)} & \text{SymFun}_{\text{lin}}^n(\mathcal{C}, \text{Sp}(\mathcal{D})) \\
\downarrow & & \downarrow \psi \\
\text{Hom}^n(\mathcal{C}, \mathcal{D}) & \xrightarrow{\text{cr}(n)} & \text{SymFun}_{\text{lin}}^n(\mathcal{C}, \mathcal{D}).
\end{array}
\]

The left vertical map is a categorical equivalence by Corollary 6.1.2.9. The functor \(\psi\) is obtained from the forgetful functor \(\psi_0 : \text{Exc}_n(\mathcal{C}, \text{Sp}(\mathcal{D})) \to \text{Exc}_n(\mathcal{C}, \mathcal{D})\) by taking homotopy invariants with respect to the action of \(\Sigma_n\). Iterated application of Corollary 6.1.2.9 shows that \(\psi_0\) is a categorical equivalence, so that \(\psi\) is a categorical equivalence. Consequently, to show that the lower horizontal map in the above diagram is a categorical equivalence, it will suffice to show that the upper horizontal map is a categorical equivalence. We may therefore replace \(\mathcal{D}\) by \(\text{Sp}(\mathcal{D})\) and thereby reduce to the case where \(\mathcal{D}\) is stable. In particular, \(\mathcal{D}\) admits finite colimits. Since \(\mathcal{D}\) admits sequential colimits, it admits countable filtered colimits, and therefore all countable colimits (Corollary T.4.2.3.11).

Let \(\prod : \mathcal{C}^{(n)} \to \mathcal{C}\) be as in Example 6.1.4.2. For every object \(C \in \mathcal{C}\), the inclusion map \(\{C\}^{(n)} \hookrightarrow \mathcal{C}^{(n)} \times \mathcal{C} \land C\) is left cofinal. Note that \(\{C\}^{(n)}\) is isomorphic to the classifying space \(B\Sigma_n = ES\Sigma_n/\Sigma_n\), which has countably many simplices. Consequently, every functor \(\{C\}^{(n)} \to \mathcal{D}\) admits a colimit in \(\mathcal{D}\). It follows that every functor \(\mathcal{C}^{(n)} \to \mathcal{D}\) admits a left Kan extension along \(\prod\). The formation of left Kan extensions defines a functor \(\psi : \text{SymFun}^n(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D})\) which may be described explicitly as follows: if \(F : \mathcal{C}^{(n)} \to \mathcal{D}\) is a symmetric \(n\)-ary functor from \(\mathcal{C}\) to \(\mathcal{D}\) with underlying functor \(f : \mathcal{C}^n \to \mathcal{D}\), then \((\psi F)(X)\) is given by extracting coinvariants with respect to the action of \(\Sigma_n\) on \(f(X, \ldots, X) \in \mathcal{D}\). Note that the functor \(\psi\) is left adjoint to the forgetful functor \(\text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{SymFun}^n(\mathcal{C}, \mathcal{D})\). It follows that \(\psi|\text{SymFun}^n(\mathcal{C}, \mathcal{D})\) is left adjoint to the symmetric cross effect construction \(\text{cr}(n) : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{SymFun}^n(\mathcal{C}, \mathcal{D})\).

We now claim that \(\psi\) carries \(\text{SymFun}_{\text{lin}}^n(\mathcal{C}, \mathcal{D})\) into \(\text{Hom}^n(\mathcal{C}, \mathcal{D})\). Let \(F : \mathcal{C}^{(n)} \to \mathcal{D}\) be a symmetric \(n\)-ary functor from \(\mathcal{C}\) to \(\mathcal{D}\) and let \(f : \mathcal{C}^n \to \mathcal{D}\) be the underlying functor. Let \(\delta : \mathcal{C} \to \mathcal{C}^n\) be the diagonal map. If \(f\) is 1-homogeneous in each variable, then \(f \circ \delta\) is \(n\)-homogeneous (Corollaries 6.1.3.4 and 6.1.3.12). Note that \(F\) restricts to a map \(\mathcal{C} \times B\Sigma_n \to \mathcal{D}\), which we can identify with a map \(\chi : B\Sigma_n \to \text{Fun}(\mathcal{C}, \mathcal{D})\) carrying the base point to \(f \circ \delta\). Moreover, \((\psi F)\) is given by the colimit of the diagram \(\chi\).

The collection of \(n\)-reduced functors from \(\mathcal{C}\) to \(\mathcal{D}\) is evidently stable under colimits. The functor \(P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D})\) is left exact by Remark 6.1.1.29. Since \(\text{Fun}(\mathcal{C}, \mathcal{D})\) is stable, the functor \(P_n\) is also right exact. Since \(P_n\) preserves sequential colimits (Remark 6.1.1.31), it preserves countable filtered colimits and therefore all countable colimits (Corollary T.4.2.3.12). It follows that the collection of \(n\)-excisive functors from \(\mathcal{C}\) to \(\mathcal{D}\) is stable under countable colimits. Since the collection of \(n\)-reduced functors is evidently stable under countable colimits, we conclude that \(\text{Hom}^n(\mathcal{C}, \mathcal{D}) \subseteq \text{Fun}(\mathcal{C}, \mathcal{D})\) is stable under countable colimits. In particular, we deduce that \(\psi(F) = \lim \chi\) is \(n\)-homogeneous. Let \(\psi_0 = \psi|\text{SymFun}_{\text{lin}}^n(\mathcal{C}, \mathcal{D})\). The above arguments show that we have a pair of adjoint functors

\[
\begin{array}{ccc}
\text{SymFun}_{\text{lin}}^n(\mathcal{C}, \mathcal{D}) & \xrightarrow{\psi_0} & \text{Hom}^n(\mathcal{C}, \mathcal{D}) \\
\downarrow \text{cr}(n) & & \downarrow \text{cr}(n) \\
\text{SymFun}_{\text{lin}}^n(\mathcal{C}, \mathcal{D}) & \xrightarrow{\psi_0} & \text{Hom}^n(\mathcal{C}, \mathcal{D}).
\end{array}
\]

We claim that these adjoint functors are mutually inverse equivalences. It follows from Corollary 6.1.4.11 (and Remark 6.1.4.6) that the functor \(\text{cr}(n)\) is conservative on \(\text{Hom}^n(\mathcal{C}, \mathcal{D})\). It will therefore suffice to show that the unit map \(u : \text{id} \to \text{cr}(n) \circ \psi_0\) is an equivalence of functors from \(\text{SymFun}_{\text{lin}}^n(\mathcal{C}, \mathcal{D})\) to itself.

Let \(F : \mathcal{C}^{(n)} \to \mathcal{D}\) be a symmetric \(n\)-ary functor such that the underlying map \(f : \mathcal{C}^n \to \mathcal{D}\) is 1-homogeneous in each variable. We wish to prove that \(u\) induces an equivalence of symmetric \(n\)-ary functors

\[
u F : F \to \text{cr}(n)(\psi F).
\]

Since the forgetful functor \(\text{SymFun}^n(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}^n, \mathcal{D})\) is conservative, it will suffice to show that the induced map \(\nu : f \to \text{cr}(n)(\psi F)\) is an equivalence. Because \(\mathcal{D}\) is stable, the formation of colimits in \(\mathcal{D}\) commutes
with finite limits. It follows that \( \text{cr}_n(\psi F) \) can be identified with the coinvariants for the permutation action of the symmetric group \( \Sigma_n \) on \( \text{cr}_n(f \circ \delta) \).

Proposition 6.1.4.13 gives a canonical equivalence \( \text{cr}_n(f \circ \delta) \cong \bigoplus_{\sigma \in \Sigma_n} f_\sigma \), where the summands are permuted by the action of \( \Sigma_n \). It follows that the \( \Sigma_n \)-coinvariants on \( \text{cr}_n(f \circ \delta) \) can be identified with the functor \( f \). Unwinding the definitions, we see that this identification is given by the map \( \nu \).

We will later need the following variant of Theorem 6.1.4.7:

**Proposition 6.1.4.14.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and a final object, let \( \mathcal{D} \) be a stable \( \infty \)-category which admits countable colimits, and let \( \psi : \text{SymFun}^n(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D}) \) be defined as in the proof of Theorem 6.1.4.7 (so that if \( F \in \text{SymFun}^n(\mathcal{C}, \mathcal{D}) \) has underlying functor \( f : \mathcal{C}^n \to \mathcal{D} \), then \( \psi(F) \) assigns to each object \( X \in \mathcal{C} \) the coinvariants for the action of the symmetric group \( \Sigma_n \) on \( f(X, \ldots, X) \)). Then composition with \( \psi \) induces an equivalence of \( \infty \)-categories

\[
\text{SymFun}^n_{\text{lin}}(\mathcal{C}, \mathcal{D}) \to \text{Homog}^n(\mathcal{C}, \mathcal{D}).
\]

**Proof.** Let \( F \in \text{SymFun}^n(\mathcal{C}, \mathcal{D}) \), and let \( f : \mathcal{C}^n \to \mathcal{D} \) be the underlying functor. Using Corollary 6.1.3.11, we deduce that the functor \( X \mapsto f(X, \ldots, X) \) is \( n \)-homogeneous. Note that \( \mathcal{D} \) and therefore \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) admit countable colimits. The \( \infty \)-category of \( n \)-reduced functors from \( \mathcal{C} \) to \( \mathcal{D} \) is evidently closed under countable colimits. The functor \( P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D}) \) is left exact by Remark 6.1.1.29, and therefore also right exact since \( \mathcal{D} \) is stable. Since \( P_n \) commutes with sequential colimits (Remark 6.1.1.31), we conclude that the class of \( n \)-excisive functors is stable under finite colimits and sequential colimits and therefore under all countable colimits. Since \( \psi(F) \) is a countable colimit of functors equivalent to \( f \), we deduce that \( \psi(F) \in \text{Homog}^n(\mathcal{C}, \mathcal{D}) \).

Let \( \mathcal{C}_* \) denote the \( \infty \)-category of pointed objects of \( \mathcal{C} \), and let \( \psi_* : \text{SymFun}^n(\mathcal{C}_*, \mathcal{D}) \to \text{Homog}^n(\mathcal{C}_*, \mathcal{D}) \) be defined as above. We have a commutative diagram

\[
\begin{array}{ccc}
\text{SymFun}^n_{\text{lin}}(\mathcal{C}, \mathcal{D}) & \xrightarrow{\psi} & \text{Homog}^n(\mathcal{C}, \mathcal{D}) \\
\downarrow {\phi} & & \downarrow {\phi'} \\
\text{SymFun}^n_{\text{lin}}(\mathcal{C}_*, \mathcal{D}) & \xrightarrow{\psi_*} & \text{Homog}^n(\mathcal{C}_*, \mathcal{D}).
\end{array}
\]

The proof of Theorem 6.1.4.7 shows that \( \psi_* \) is left adjoint to an equivalence of \( \infty \)-categories, and is therefore itself an equivalence of \( \infty \)-categories. The map \( \phi' \) is an equivalence of \( \infty \)-categories by Proposition 6.1.2.11. It will therefore suffice to show that \( \phi \) is an equivalence of \( \infty \)-categories. Note that \( \phi \) is obtained from a functor \( \phi_0 : \text{Exc}_*(\mathcal{C}_*, \mathcal{D}) \to \text{Exc}_*(\mathcal{C}^n, \mathcal{D}) \) by taking homotopy invariants with respect to the action of the symmetric group \( \Sigma_n \). Here \( \text{Homog}^{(1, \ldots, 1)}(\mathcal{C}^n, \mathcal{D}) \) denotes the full subcategory of \( \text{Fun}(\mathcal{C}^n, \mathcal{D}) \) spanned by those functors which are \( (1, \ldots, 1) \)-homogeneous, and \( \text{Exc}_*(\mathcal{C}^n, \mathcal{D}) \) is defined similarly. It will therefore suffice to show that \( \phi_0 \) is an equivalence of \( \infty \)-categories. This follows from \( n \) applications of Proposition 6.1.2.11.

**Corollary 6.1.4.15.** Let \( F : \text{Sp} \to \text{Sp} \) be a functor, and let \( n \geq 0 \) be an integer. The following conditions are equivalent:

1. The functor \( F \) is \( n \)-excisive and commutes with filtered colimits.
2. The functor \( F \) is polynomial of degree \( \leq n \), in the sense of Definition 6.1.0.2.

**Proof.** Let \( \text{Poly}^n(\text{Sp}, \text{Sp}) \subseteq \text{Fun}(\text{Sp}, \text{Sp}) \) be as in Definition 6.1.0.2, and let \( \mathcal{X} \subseteq \text{Fun}(\text{Sp}, \text{Sp}) \) be the full subcategory spanned by those functors which are \( n \)-excisive and commute with filtered colimits. We first show that (2) \( \Rightarrow \) (1): that is, \( \text{Poly}^n(\text{Sp}, \text{Sp}) \subseteq \mathcal{X} \). For \( 0 \leq m \leq n \), the functor \( X \mapsto X^{\otimes m} \) obviously commutes with filtered colimits, and is \( n \)-excisive by Corollary 6.1.3.5. It will therefore suffice to show that the subcategory \( \mathcal{X} \subseteq \text{Fun}(\text{Sp}, \text{Sp}) \) is closed under translation and small colimits. The collection of functors \( F : \text{Sp} \to \text{Sp} \) which commute with filtered colimits is closed under translations and small colimits by Lemma

\[
\begin{array}{ccc}
\text{SymFun}^n_{\text{lin}}(\mathcal{C}, \mathcal{D}) & \xrightarrow{\psi} & \text{Homog}^n(\mathcal{C}, \mathcal{D}) \\
\downarrow {\phi} & & \downarrow {\phi'} \\
\text{SymFun}^n_{\text{lin}}(\mathcal{C}_*, \mathcal{D}) & \xrightarrow{\psi_*} & \text{Homog}^n(\mathcal{C}_*, \mathcal{D}).
\end{array}
\]
Proposition 6.1.5.4. Let \( n \) those functors which are \( n \)-finite limits and filtered colimits. We let \( \text{Exc}^n \) subcategory of \( \text{Fun}(\text{Sp}, \text{Sp}) \). composition with the Yoneda embedding \( j: \mathcal{C} \rightarrow \text{Ind}(\mathcal{C}) \) which admits finite limits and small filtered colimits. Assume that filtered colimits in \( \mathcal{D} \) are left exact. Then composition with the Yoneda embedding \( j: \mathcal{C} \rightarrow \text{Ind}(\mathcal{C}) \) induces a fully faithful functor

\[
\theta: \text{Exc}^n(\text{Ind}(\mathcal{C}), \mathcal{D}) \rightarrow \text{Fun}(\mathcal{C}, \mathcal{D}),
\]

whose essential image is the full subcategory \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \subseteq \text{Fun}(\mathcal{C}, \mathcal{D}) \) spanned by the \( n \)-excisive functors.
6.1. THE CALCULUS OF FUNCTORS

Proof. Let $\text{Fun}_n(\text{Ind}(\mathcal{C}), \mathcal{D})$ be the full subcategory of $\text{Fun}(\text{Ind}(\mathcal{C}), \mathcal{D})$ spanned by those functors which preserve small filtered colimits. Proposition T.5.3.10 implies that the forgetful functor $\text{Fun}_n(\text{Ind}(\mathcal{C}), \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D})$ is an equivalence of $\infty$-categories. It follows immediately that $\theta$ is fully faithful. The Yoneda embedding $j: \mathcal{C} \to \text{Ind}(\mathcal{C})$ preserves finite colimits (Proposition T.5.3.14) and therefore carries strongly coCartesian cubes to strongly coCartesian cubes. It follows that the essential image of $\theta$ is contained in $\text{Exc}^n(\mathcal{C}, \mathcal{D})$. Conversely, suppose that $f: \mathcal{C} \to \mathcal{D}$ is an $n$-excisive functor which factors as a composition

$$
\mathcal{C} \xrightarrow{j} \text{Ind}(\mathcal{C}) \xrightarrow{F} \mathcal{D}
$$

where $F$ preserves small filtered colimits. We wish to show that $F$ is $n$-excisive. Let $S = [n] = \{0, \ldots, n\}$ and let $X : N(\mathcal{P}(S)) \to \text{Ind}(\mathcal{C})$ be a strongly coCartesian $S$-cube. We wish to show that $F(X)$ is a Cartesian $S$-cube in $\mathcal{D}$. Let $X_{\leq 1} = X| N(\mathcal{P}_{\leq 1}(S))$. Using Proposition T.5.3.15, we can write $X_{\leq 1}$ as a small filtered colimits of diagrams $j \circ Y^\alpha$, where $Y$ is a functor $N(\mathcal{P}_{\leq 1}(S)) \to \mathcal{C}$. We can extend each $Y^\alpha$ to a strongly coCartesian $S$-cube $Z^\alpha : N(\mathcal{P}(S)) \to \mathcal{C}$, so that $X \simeq \lim_{\longrightarrow} (j \circ Z^\alpha)$. Since $F$ commutes with small filtered colimits, we have $F(X) \simeq \lim_{\longrightarrow} f(Z^\alpha)$. Since filtered colimits in $\mathcal{D}$ commute with finite limits, it will suffice to show that $f(Z^\alpha)$ is a Cartesian $S$-cube in $\mathcal{D}$. This follows from our assumption that $f$ is $n$-excisive.  

By Theorem 6.1.5.6 immediately implies Theorem 6.1.5.1 (take $\mathcal{C} = \Delta^0$ and $\mathcal{D} = \text{Sp}$). Together with Proposition 6.1.5.4, it implies the following version of Corollary 6.1.5.2.

**Corollary 6.1.5.7.** Let $\mathcal{C}$ be a small $\infty$-category and let $\mathcal{D}$ be a presentable stable $\infty$-category. Then the restriction functors

$$
\text{Exc}^n(\mathcal{P}(\mathcal{C}), \mathcal{D}) \to \text{Exc}^n(\mathcal{P}^e(\mathcal{C}), \mathcal{D}) \to \text{Fun}(\mathcal{P}^e(\mathcal{C}), \mathcal{D})
$$

are equivalences of $\infty$-categories.

The proof of Theorem 6.1.5.6 will require some preliminary results.

**Lemma 6.1.5.8.** Suppose we are given $\infty$-categories $\mathcal{C}_1, \ldots, \mathcal{C}_m$, and $\mathcal{C}$ which admit finite colimits, and a functor $F: \mathcal{C}_1 \times \cdots \times \mathcal{C}_m \to \mathcal{C}$ which preserves finite colimits separately in each variable. Let $S$ be a finite set and suppose we are given $S$-cubes $X_i : N(\mathcal{P}(S)) \to \mathcal{C}_i$. Let $X$ denote the $S$-cube in $\mathcal{C}$ given by the composite

$$
N(\mathcal{P}(S)) \xrightarrow{\prod X_i} \prod \mathcal{C}_i \xrightarrow{F} \mathcal{C}.
$$

Suppose we are given integers $a_i$ such that each $X_i$ is a left Kan extension of $X_i| N(\mathcal{P}_{\leq a_i}(S))$. Then $X$ is a left Kan extension of $X| N(\mathcal{P}_{\leq a}(S))$, where $a = a_1 + \cdots + a_m$. 

Proof. Define \( Y : \mathcal{N}(\mathbf{P}(\mathbf{S}))^m \to \mathcal{C} \) by the formula \( Y(S_1, \ldots, S_m) = F(X_1(S_1), \ldots, X_m(S_m)) \). Let \( A \subseteq \mathbf{P}(\mathbf{S})^m \) be the subset consisting of sequences \((S_1, \ldots, S_m)\) where \( S_1 = \cdots = S_m \) and each \( S_i \) has cardinality \( \leq a \). We wish to show that \( Y \) exhibits \( Y(S_1, \ldots, S) \) as a colimit of the diagram \( Y|\mathcal{N}(A) \). Let \( B_0 \subseteq \mathbf{P}(\mathbf{S})^m \) be the subset consisting of sequences \((S_1, \ldots, S_m)\) such that the union \( \bigcup_i S_i \) has cardinality \( \leq a \). Then \( A \subseteq B \). The inclusion \( \mathcal{N}(A) \to \mathcal{N}(B) \) admits a left adjoint and is therefore left cofinal. It will therefore suffice to show that \( Y \) exhibits \( Y(S_1, \ldots, S) \) as a colimit of \( Y|\mathcal{N}(B) \). We will prove the following stronger result: \( Y \) is a left Kan extension of \( Y|\mathcal{N}(B) \).

Choose a sequence of downward-closed subsets \( B = B_0 \subseteq B_1 \subseteq \cdots \subseteq B_k = \mathbf{P}(\mathbf{S})^m \), where each \( B_j \) is obtained from \( B_{j-1} \) by adjoining a single element of \( \mathbf{P}(\mathbf{S})^m \). To complete the proof, it will suffice to show that \( Y|\mathcal{N}(B_j) \) is a left Kan extension of \( Y|\mathcal{N}(B_{j-1}) \) for \( 0 < j \leq k \). Suppose that \( B_j \) is obtained from \( B_{j-1} \) by adjoining the element \((S_1, \ldots, S_m)\) \( \in \mathbf{P}(\mathbf{S})^m \). Unwinding the definitions, we must show that \( Y| \prod_{1 \leq i \leq m} \mathcal{N}(\mathbf{P}(S_i)) \) is a colimit diagram in \( \mathcal{C} \).

Since \((S_1, \ldots, S_m) \notin B_0 \), the union \( \bigcup_i S_i \) has cardinality larger than \( a \). It follows that some \( S_i \) has cardinality larger than \( a_1 \). Without loss of generality, we may assume that \( S_1 \) has cardinality larger than \( a_1 \). Let \( P = (\prod_{1 \leq i \leq m} \mathbf{P}(S_i)) - \{(S_1, \ldots, S_m)\} \), and let \( P_0 \subseteq P \) be the subset spanned by those sequences \((T_1, \ldots, T_m)\) such that \( T_1 \neq S_1 \), and let \( P_1 \subseteq P_0 \) be the subset consisting of those sequences having the form \((T_1, S_2, S_3, \ldots, S_m)\). Using the fact that \( X_1 \) is a left Kan extension of \( X_1|\mathcal{N}(\mathbf{P}(S_1)) \) and that \( F \) preserves finite colimits in the first variable, we deduce that \( Y|\mathcal{N}(P) \) is a left Kan extension of the diagram \( Y|\mathcal{N}(P_0) \). It will therefore suffice to show that \( Y \) exhibits \( Y(S_1, \ldots, S_m) \) as a colimit of \( Y|\mathcal{N}(P_0) \). Note that the inclusion \( P_1 \subseteq P_0 \) admits a left adjoint (given by \((T_1, \ldots, T_m) \mapsto (T_1, S_2, S_3, \ldots, S_m)\) and therefore induces a left cofinal map \( N(P_1) \to N(P_0) \). We are therefore reduced to proving that \( Y \) exhibits \( Y(S_1, \ldots, S_m) \) as a colimit of \( Y|\mathcal{N}(P_1) \). Since \( F \) preserves finite colimits in the first variable, it suffices to show that \( X_1|\mathcal{N}(S_1) \) is a colimit diagram. Since \( S_1 \) has cardinality larger than \( a_1 \), this follows from our assumption that \( X_1 \) is a left Kan extension of \( X_1|\mathcal{N}(\mathbf{P}(S_1)) \).

\[ \square \]

**Lemma 6.1.5.9.** Let \( \mathcal{C} \) be a presentable \( \infty \)-category and let \( \mathcal{D} \) be a presentable stable \( \infty \)-category. Let \( F : \mathcal{C} \to \mathcal{D} \) be a 1-exciscive functor such that the composition \( F_* : \mathcal{C}_* \to \mathcal{C} \xrightarrow{\mathcal{F}} \mathcal{D} \) preserves small filtered colimits. Then \( F \) preserves small filtered colimits.

**Proof.** Let \( \emptyset \) and \( * \) denote initial and final objects of \( \mathcal{C} \), respectively, and let \( G_0 \) and \( G_* \) denote the constant functors \( \mathcal{C} \to \mathcal{C} \) taking the values \( \emptyset \) and \( * \). Let \( U \) denote the pushout \( \prod_{G_*} G_* \), formed in the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{C}) \). Since \( F \) is 1-exciscive, we obtain a pullback diagram of functors

\[
\begin{array}{ccc}
F \circ G_0 & \to & F \circ G_* \\
\downarrow & & \downarrow \\
F & \to & F \circ U.
\end{array}
\]

It follows that the fiber of the map \( F \to F \circ U \) is equivalent to a constant functor from \( \mathcal{C} \) to \( \mathcal{D} \), and therefore commutes with filtered colimits. Consequently, to prove that \( F \) commutes with filtered colimits, it will suffice to show that \( F \circ U \) commutes with filtered colimits. This is clear, since \( F \circ U \) factors as a composition \( \mathcal{C} \xrightarrow{T} \mathcal{C}_* \xrightarrow{F_*} \mathcal{D} \), where \( T \) is a left adjoint to the forgetful functor \( \mathcal{C}_* \to \mathcal{C} \).

\[ \square \]

**Remark 6.1.5.10.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits, and \( \mathcal{D} \) a stable \( \infty \)-category which admits small colimits. The inclusion functor \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D}) \) is a left exact functor between stable \( \infty \)-categories, and therefore right exact. It follows that the collection of \( n \)-exciscive functors from \( \mathcal{C} \) to \( \mathcal{D} \) is closed under finite colimits. The collection of \( n \)-exciscive functors from \( \mathcal{C} \) to \( \mathcal{D} \) is also closed under small filtered colimits (since filtered colimits in \( \mathcal{D} \) are left exact), and therefore closed under all small colimits.
6.1. THE CALCULUS OF FUNCTORS

Proof of Theorem 6.1.5.6. We first show that (1) ⇒ (2). Since the ∞-category D is presentable, we can regard it as tensored over the ∞-category S of spaces (see §4.8.1.14); we let ⊗ : S × D → D denote the corresponding tensor product functor. Let E = Fun(PEndS(Δ), D). For every object X ∈ PEnd S(Δ), let X*: E → D be the functor given by evaluation at X. This functor admits a left adjoint X!, which is given on objects by the formula (X!(D))(Y) = MapD(X, Y) ⊗ D.

Let E₀ ⊆ E be the smallest full subcategory which contains the essential image of each of the functors X₁ and is closed under small colimits. We claim that E₀ = E. Note that both E₀ and E are presentable, so Corollary T.5.5.2.9 implies that the inclusion E₀ ⊆ E admits a right adjoint G. To prove that E₀ = E, it will suffice to show that G is conservative. This is clear: if α : E → E’ is a morphism in E such that G(α) is an equivalence, then X*(α) is an equivalence for each X ∈ PEnd S(Δ) and therefore α is an equivalence.

Let E₁ denote the full subcategory of E spanned by those functors E : PEnd S(Δ) → D satisfying the following condition: if E : P(Δ) → D is a left Kan extension of E, then E is n-excisive and preserves filtered colimits. We wish to show that E₁ = E. In view of the preceding arguments, it will suffice to show that E₀ ⊆ E₁. Note that E₁ is closed under small colimits in E by Remark 6.1.5.10. It will therefore suffice to show that E₁ contains the functor X₁(D), for each X ∈ PEnd S(Δ) and each D ∈ D. Since X is a compact object of P(Δ), the functor X₁(D) preserves small filtered colimits. We must show that it is n-excisive.

Let j : C → P(Δ) denote the Yoneda embedding, so we can write X = ⊓i≤n j(Cᵢ) for some objects Cᵢ ∈ C, where m ≤ n. We will show that X₁(D) is m-excisive. Let S = [m] = {0, ..., m} and choose a strongly coCartesian S-cube of spaces Y : N(P(S)) → P(Δ). We wish to prove that (X₁(D))(Y) is a Cartesian S-cube in D. According to Proposition 1.2.4.13, it will suffice to show that (X₁(D))(Y) is a colimit diagram in D. Using the formula for X₁(D) given above, we are reduced to proving that the S-cube of spaces \{MapP(x, Y(T))\}_T⊂S is a colimit diagram: that is, it is a left Kan extension of its restriction to N(Pₘₙ(S)). Note that this cube is equivalent to a product of the S-cubes of spaces given by \{(Y(T))(Cᵢ)\}_T⊂S, each of which is strongly coCartesian (since we assumed that Y is strongly coCartesian). The desired result now follows from Lemma 6.1.5.8. This completes the proof that (1) ⇒ (2).

We now prove that (2) ⇒ (1). Let E’ ⊆ Fun(P(Δ), D) be the full subcategory of Fun(P(Δ), D) spanned by those functors which are left Kan extensions of their restrictions to PEnd S(Δ). We wish to show that if F : P(Δ) → D is an excisive functor which commutes with filtered colimits, then F ∈ E’. The proof proceeds by induction on n. If n = 0, then F is constant functor and the result is obvious. Assume that n > 0. It follows from the inductive hypothesis (and the transitivity of left Kan extensions) that E’ contains every (n − 1)-excisive functor which commutes with filtered colimits. Applying Theorem 6.1.2.4, we obtain a fiber sequence of functors

\[ F → P_{n-1}F → R \]

where R is n-homogeneous. Using the assumption that F commutes with filtered colimits and the construction of Pₙ₋₁, we conclude that Pₙ₋₁F commutes with filtered colimits. It follows that Pₙ₋₁F ∈ E’ and that R commutes with filtered colimits. Consequently, we may replace F by R and thereby reduce to the case where F is homogeneous.

Let ψ : SymFunInₙ(P(Δ), D) → HomGoₙ(Δ, D) be the equivalence of Proposition 6.1.4.14. We may assume that F = ψ(Π) for some Π ∈ SymFunInₙ(P(Δ), D). Let H : P(Δ) → D be the n-ary functor underlying Π, so that H is 1-homogeneous in each variable. The proof of Proposition 6.1.4.14 shows that the restriction H|PEnd S(Δ) is given by the cross effect crₙ(F|PEnd S(Δ)), and therefore preserves filtered colimits separately in each variable. Using Lemma 6.1.5.9, we conclude that H preserves filtered colimits separately in each variable. Let δ : P(Δ) → P(Δ)ₙ be the diagonal map, so that F is the colimit of a diagram \(BS_n → Fun(P(Δ), D)\) carrying the vertex to \(H ◦ δ\). Since E’ is closed under small colimits, it will suffice to show that \(H ◦ δ ∈ E’\). Let E’’ ⊆ Fun(P(Δ)ₙ, D) be the full subcategory spanned by those functors G : P(Δ)ₙ → D such that G ◦ δ ∈ E’. To complete the proof, it will suffice to show the following:

(*) Any functor G : P(Δ)ₙ → D which commutes with filtered colimits and is 1-excisive in each variable belongs to E’’.

The proof of (*) proceeds by induction on n. Suppose that G : P(Δ)ₙ → D commutes with filtered colimits and is 1-excisive in each variable. Fix 1 ≤ i ≤ n, let ∅ denote an initial object of P_Δ, and define
Let $C$. 

**6.1.6 Norm Maps**

The inductive hypothesis implies that $G' \in \mathcal{E}''$. Consequently, to prove that $G \in \mathcal{E}''$ it will suffice to show that $G'' \in \mathcal{E}''$. As a functor of its $i$th argument, $G''$ is $1$-excisive and preserves initial objects, and is therefore right exact. Since $G''$ preserves filtered colimits in the $i$th argument, we conclude that $G''$ preserves small colimits in the $i$th argument. Replacing $G$ by $G''$, we can assume that $G$ preserves small colimits in the $i$th argument. Applying this argument repeatedly, we can reduce to the case where $G$ preserves small colimits separately in each variable. Let $j : \mathcal{C}^n \to \mathcal{P}(\mathcal{E})^n$ be the $n$th power of the Yoneda embedding. Using Lemma T.5.1.5.5 repeatedly, we deduce that $G$ is a left Kan extension of $g = G \circ j$ along $j$. It will therefore suffice to prove the following:

$(\ast')$ Let $g : \mathcal{E}^n \to \mathcal{D}$ be any functor, and let $G : \mathcal{P}(\mathcal{E})^n \to \mathcal{D}$ be a left Kan extension of $g$ along $j : \mathcal{E}^n \to \mathcal{P}(\mathcal{E})^n$. Then $G \in \mathcal{E}''$.

Let $\mathcal{X}$ denote the full subcategory of $\mathcal{F}(\mathcal{E}^n, \mathcal{D})$ spanned by those functors $g$ such that $G \in \mathcal{E}''$, where $G$ is a left Kan extension of $g$ along $j$. We wish to prove that $\mathcal{X} = \mathcal{F}(\mathcal{E}^n, \mathcal{D})$. For each object $\mathcal{C} = (C_1, \ldots, C_n) \in \mathcal{E}^n$, let $e_{\mathcal{C}} : \mathcal{F}(\mathcal{E}^n, \mathcal{D}) \to \mathcal{D}$ be the functor given by evaluation at $\mathcal{C}$, and let $\mathcal{C}_1 : \mathcal{D} \to \mathcal{F}(\mathcal{E}^n, \mathcal{D})$ be a left adjoint to $e_{\mathcal{C}}$, so that $\mathcal{C}_1$ is given by the formula

$$(\mathcal{C}_1(D))(Y_1, \ldots, Y_n) = (\prod_i \text{Map}_\mathcal{E}(C_i, Y_i)) \otimes D.$$ 

Let $\mathcal{X}'$ denote the smallest full subcategory of $\mathcal{F}(\mathcal{E}^n, \mathcal{D})$ which is closed under small colimits and contains all objects of the form $\mathcal{C}_1(D)$. Then $\mathcal{X}'$ is a presentable $\omega$-category which is closed under colimits in $\mathcal{F}(\mathcal{E}^n, \mathcal{D})$, so Corollary T.5.5.2.9 implies that the inclusion $\mathcal{X}' \to \mathcal{F}(\mathcal{E}^n, \mathcal{D})$ admits a right adjoint $U$. We claim that $\mathcal{X}' = \mathcal{F}(\mathcal{E}^n, \mathcal{D})$. To prove this, it suffices to show that $U$ is conservative. This is clear: if $\alpha : g \to g'$ is a morphism in $\mathcal{F}(\mathcal{E}^n, \mathcal{D})$ such that $U(\alpha)$ is an equivalence, then $e_{\mathcal{C}}(\alpha)$ is an equivalence for each $\mathcal{C} \in \mathcal{E}^n$. Consequently, to prove that $\mathcal{X} = \mathcal{F}(\mathcal{E}^n, \mathcal{D})$, it will suffice to prove that $\mathcal{X}' \subseteq \mathcal{X}$. Because $\mathcal{X}$ is closed under small colimits in $\mathcal{F}(\mathcal{E}^n, \mathcal{D})$, it will suffice to show that $\mathcal{X}$ contains every object of the form $g = \mathcal{C}_1(D)$, where $\mathcal{C} = (C_1, \ldots, C_n) \in \mathcal{E}^n$ and $D \in \mathcal{D}$. Let $G : \mathcal{P}(\mathcal{E})^n \to \mathcal{D}$ be a left Kan extension of $g$ along $j$. Unwinding the definitions, we see that $G$ is given by the formula $G(X_1, \ldots, X_n) = (\prod_i X_i(C_i)) \otimes D$. In particular, $G \circ \delta$ is the functor given by

$$X \mapsto (\prod_i X(C_i)) \otimes D \cong \text{Map}_{\mathcal{P}(\mathcal{E})}(X_0, X) \otimes D,$$

where $X_0 \in \mathcal{P}^{\leq n}(\mathcal{E})$ denotes the coproduct of the functors represented by the objects $C_i \in \mathcal{E}$. It follows that $G \circ \delta$ is the left Kan extension of a constant functor (taking the value $D$) on the $\omega$-category $\{X_0\} \subseteq \mathcal{P}^{\leq n}(\mathcal{E})$, and therefore belongs to $\mathcal{E}'$ as desired.

**6.1.6 Norm Maps**

Let $\mathcal{C}$ and $\mathcal{D}$ be pointed $\omega$-categories, where $\mathcal{C}$ admits finite colimits and $\mathcal{D}$ is a differentiable $\omega$-category. According to Theorem 6.1.2.5, every reduced $n$-excisive functor from $\mathcal{C}$ to $\mathcal{D}$ can be described (in an essentially unique way) as the fiber of an “attaching map” $\nu : F \to G$ in $\mathcal{F}(\mathcal{C}, \mathcal{D})$, where $F$ is reduced and $(n - 1)$-excisive and $G$ is $n$-homogeneous. Consequently, the classification of all $n$-excisive functors from $\mathcal{C}$ to $\mathcal{D}$ can be broken into three problems:

(a) Classify all $(n - 1)$-excisive functors from $\mathcal{C}$ to $\mathcal{D}$.

(b) Classify all $n$-homogeneous functors from $\mathcal{C}$ to $\mathcal{D}$.

(c) Given $F \in \text{Exc}_{n-1}^{\ast}\mathcal{C}, \mathcal{D})$ and $G \in \text{Homog}^n(\mathcal{C}, \mathcal{D})$, classify all natural transformations $\nu : F \to G$. 

6.1. THE CALCULUS OF FUNCTORS

We can regard (a) as a simpler instance of the same problem (note that if \( n = 0 \), then \( \text{Exc}^n(\mathcal{C}, \mathcal{D}) \) is a contractible Kan complex), and (b) is addressed in §6.1.4. In this section, we will discuss problem (c) in the special case where \( \mathcal{C} \) and \( \mathcal{D} \) are stable, and \( \mathcal{D} \) admits countable limits. In this case, every \( n \)-homogeneous functor \( G : \mathcal{C} \to \mathcal{D} \) can be described by the formula \( C \mapsto g(C, C, \ldots, C)_{\Sigma_n} \), where \( g : \mathcal{C}^{(n)} \to \mathcal{D} \) is an symmetric \( n \)-ary functor from \( \mathcal{C} \) to \( \mathcal{D} \) which is exact in each variable. In this situation, we will show that there is a universal example of an \((n - 1)\)-excisive functor \( F \) equipped with a natural transformation \( F \to G \).

We can describe \( F \) explicitly as the functor which carries an object \( C \in \mathcal{C} \) to the fiber of the norm map

\[
\text{Nm} : g(C, C, \ldots, C)_{\Sigma_n} \to g(C, C, \ldots, C)^{\Sigma_n}.
\]

We begin with a general discussion. Let \( M \) be an abelian group equipped with an action of a group \( G \). We can associate to \( M \) the subgroup \( M^G = \{ x \in M : (\forall g \in G)[g(x) = x]\} \) consisting of \( G \)-invariant elements, as well as the quotient group \( M_G = M / K \), where \( K \) is the subgroup of \( M \) generated by all elements of the form \( g(x) - x \). When the group \( G \) is finite, there is a canonical norm map

\[
\text{Nm} : M_G \to M^G,
\]

which is induced by the map from \( M \) to itself given by \( x \mapsto \sum_{g \in G} g(x) \). Our first goal in this section is to describe an analogous construction in the \( \infty \)-categorical setting.

**Notation 6.1.6.1.** Let \( \mathcal{C} \) be an \( \infty \)-category and \( X \) a Kan complex. We let \( \mathcal{C}^X \) denote the \( \infty \)-category \( \text{Fun}(X, \mathcal{C}) \) of all maps from \( X \) to \( \mathcal{C} \). If \( f : X \to Y \) is a map of Kan complexes, then composition with \( f \) induces a map \( f^* : \mathcal{C}^Y \to \mathcal{C}^X \). Assume that \( \mathcal{C} \) admits limits and colimits indexed by the simplicial sets \( X \times Y_{/y} \), for each \( y \in Y \). Then \( f^* \) admits left and right adjoints, which we denote by \( f_* \) and \( f_! \), respectively.

**Example 6.1.6.2.** Let \( G \) be a group and \( BG \) its classifying space (which we regard as a Kan complex). If \( \mathcal{C} \) is an \( \infty \)-category, we define a \( G \)-equivariant object of \( \mathcal{C} \) is an object of \( \mathcal{C}^{BG} \). Let \( f : BG \to \Delta^n \) be the projection map. If \( \mathcal{C} \) admits small limits and colimits, then we have functors \( f_* : \mathcal{C}^{BG} \to \mathcal{C} \). We will denote these functors by \( M \mapsto M^G \) and \( M \mapsto M_G \), respectively.

We can now formulate our problem more precisely. Let \( G \) be a finite group, \( f : BG \to \Delta^0 \) the projection map, and \( \mathcal{C} \) be a sufficiently nice \( \infty \)-category. We wish to associate to the pair \((G, \mathcal{C})\) a natural transformation \( \text{Nm} : f_! \to f_* \). That is, we wish to construct a natural map \( M_G \to M^G \) for each \( G \)-equivariant object \( M \in \mathcal{C} \).

It will be convenient to construct this natural transformation more generally for any map \( f : X \to Y \) having reasonably simple homotopy fibers. We will proceed in several steps, each time allowing slightly more general homotopy fibers.

**Lemma 6.1.6.3.** Suppose we are given a homotopy pullback diagram of Kan complexes \( \sigma : \)

\[
\begin{array}{ccc}
X' & \xrightarrow{f'} & Y' \\
\downarrow g' & & \downarrow g' \\
X & \xrightarrow{f} & Y.
\end{array}
\]

Let \( \mathcal{C} \) be an \( \infty \)-category, and assume that for each \( y \in Y \) the \( \infty \)-category \( \mathcal{C} \) admits limits indexed by the Kan complex \( X \times_Y Y_{/y} \). Then the diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C}^Y & \longrightarrow & \mathcal{C}^X \\
\downarrow & & \downarrow \\
\mathcal{C}^{Y'} & \longrightarrow & \mathcal{C}^{X'}
\end{array}
\]

is right adjointable.
Proof. Let \( \mathcal{F} : X \to \mathcal{C} \) be a functor; we wish to show that the canonical map \( g^* f_* \mathcal{F} \to f^* g^* \mathcal{F} \) is an equivalence in \( \mathcal{C}' \). Unwinding the definition, we must show that for each vertex \( y' \in Y' \), the map
\[
\lim (\mathcal{F} | X \times_Y Y_{y'}) \to \lim (\mathcal{F} | X' \times_{Y'} Y'_{y'})
\]
is an equivalence in \( \mathcal{C} \). This follows from the fact that the map \( X' \times_{Y'} Y'_{y'} \to X \times_Y Y_{y'} \) is a homotopy equivalence, since we have assumed that \( \sigma \) is a homotopy pullback diagram. \( \square \)

**Construction 6.1.6.4.** Let \( \mathcal{C} \) be an \( \infty \)-category which has both an initial object and a final object. It follows that for any map of Kan complexes \( f : X \to Y \) with \((-1\)-truncated homotopy fibers, the pullback functor \( f^* : \mathcal{C}' \to \mathcal{C}^X \) admits left and right adjoints \( f! \) and \( f_* \), given by left and right Kan extension along \( f \).

Let \( X \times_Y X \) denote the homotopy fiber product of \( X \) with itself over \( Y \) and let \( \delta : X \to X \times_X X \) be the diagonal map. Since \( f \) is \((-1\)-truncated, \( \delta \) is a homotopy equivalence. It follows that the Kan extension functors \( \delta_!, \delta_* : \mathcal{C}^X \to \mathcal{C}^{X \times_X X} \) are both homotopy inverse to \( \delta^* \), so there is a canonical equivalence \( \delta_* \to \delta_! \). Let \( p_0, p_1 : X \times_X X \to X \) be the projection onto the first and second factor, respectively. We have a natural transformation of functors
\[
p_0^* \to \delta_* \delta_! p_0^* \simeq \delta_* \simeq \delta_! \simeq \delta_! \delta^* p_1^* \to p_1^*
\]
which is adjoint to a natural transformation \( \beta : \text{id}_{\mathcal{C}^X} \to (p_0)_! p_1^* \). Since we have a homotopy pullback diagram
\[
\begin{array}{ccc}
X \times_Y X & \xrightarrow{p_0} & X \\
\downarrow & & \downarrow f \\
X & \xrightarrow{f} & Y,
\end{array}
\]
Lemma 6.1.6.3 implies that the canonical map \( f^* f_* \to (p_0)_! p_1^* \) is an equivalence, so that \( \beta \) determines a natural transformation \( \text{id}_{\mathcal{C}^X} \to f^* f_* \), which is in turn adjoint to a map \( \text{Nm}_f : f_! \to f_* \). We will refer to \( \text{Nm}_f \) as the *norm map* determined by \( f \).

**Example 6.1.6.5.** Let \( \mathcal{C} \) be an \( \infty \)-category with initial and final objects and let \( f : X \to Y \) be a homotopy equivalence of Kan complexes. Then the natural transformation \( \text{Nm}_f : f_! \to f_* \) of Construction 6.1.6.4 is the equivalence determined by the observation that \( f_! \) and \( f_* \) are both homotopy inverse to \( f^* \); in other words, it is determined by the requirement that the induced map \( f^* f_! \to f^* f_* \) is homotopy inverse to the composition of counit and unit maps
\[
f^* f_* \to \text{id}_{\mathcal{C}^X} \to f^* f_!.
\]

**Example 6.1.6.6.** Let \( Y = \Delta^0 \) and let \( \mathcal{C} \) be an \( \infty \)-category with initial and final objects. If \( f : X \to Y \) is a \((-1\)-truncated map of Kan complexes, then \( X \) is either empty or contractible. If \( X \) is contractible, then the norm map \( \text{Nm}_f \) is the equivalence described in Example 6.1.6.5. If \( X = \emptyset \), then \( \mathcal{C}^X \simeq \Delta^0 \) and the functors \( f_! \) and \( f_* \) can be identified with initial and final objects of \( \mathcal{C} \simeq \mathcal{C}^Y \), respectively. In this case, the norm map \( \text{Nm}_f \) is determined up to a contractible space of choices, since it is a map from an initial object of \( \mathcal{C} \) to a final object of \( \mathcal{C} \).

**Proposition 6.1.6.7.** Let \( \mathcal{C} \) be an \( \infty \)-category with an initial and final object. The following conditions are equivalent:

1. For every map of Kan complexes \( f : X \to Y \) with \((-1\)-truncated homotopy fibers, the norm map \( \text{Nm}_f : f_! \to f_* \) is an equivalence.
2. Condition (1) holds whenever \( Y = \Delta^0 \).
3. The \( \infty \)-category \( \mathcal{C} \) is pointed.
which classifies a collection of maps \( \phi \) with the map can identify objects of \( C \) a finite set (regarded as a discrete simplicial set), and let Example 6.1.6.11. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite products and coproducts. It follows that for any map of Kan complexes \( f : X \to Y \) whose homotopy fibers are 0-truncated and have finitely many path components, the pullback functor \( f^* : \mathcal{C}^Y \to \mathcal{C}^X \) admits left and right adjoints \( f_! \) and \( f_* \), given by left and right Kan extension along \( f \).

Let \( X \times_Y X \) denote the homotopy fiber product of \( X \) with itself over \( Y \) and let \( \delta : X \to X \times_Y X \) be the diagonal map. Since \( f \) is 0-truncated, the map \( \delta \) is \((-1)\)-truncated, so that Construction 6.1.6.4 defines a norm map \( Nm_\delta : \delta_! \to \delta_* \). Assume that \( \mathcal{C} \) is pointed. Proposition 6.1.6.7 implies that \( Nm_\delta \) is an equivalence, and therefore admits a homotopy inverse \( Nm_\delta^{-1} : \delta_* \to \delta_! \).

Let \( p_0, p_1 : X \times_Y X \to X \) be the projection onto the first and second factor, respectively. We have a natural transformation of functors

\[
p_0^* \to \delta_* \delta^* p_0^* \xrightarrow{Nm_{\delta_!}^{-1}} \delta_* \simeq \delta_! \simeq \delta_! \delta^* \to \to p_1^*
\]

which is adjoint to a natural transformation \( \beta : \text{id}_{\mathcal{C}^X} \to (p_0)_*, p_1^* \). Since we have a homotopy pullback diagram

\[
\begin{array}{ccc}
X \times_Y X & \xrightarrow{p_0} & X \\
\downarrow p_1 & & \downarrow f \\
X & \xrightarrow{f} & Y,
\end{array}
\]

Lemma 6.1.6.3 implies that the canonical map \( f^* f_* \to (p_0)_*, p_1^* \) is an equivalence, so that \( \beta \) determines a map \( \text{id}_{\mathcal{C}^X} \to f^* f_* \), which is adjoint to a natural transformation \( Nm_f : f_! \to f_* \). We will refer to \( Nm_f \) as the norm map determined by \( f \).

Remark 6.1.6.9. In the situation of Construction 6.1.6.8, assume that \( f \) is \((-1)\)-truncated. Then our definition of \( Nm_f \) is unambiguous: in other words, the natural transformations \( Nm_f : f_! \to f_* \) described in Constructions 6.1.6.4 and 6.1.6.8 agree. This follows immediately from Example 6.1.6.5.

Remark 6.1.6.10. Suppose we are given a homotopy pullback diagram

\[
\begin{array}{ccc}
X' & \xrightarrow{f'} & Y' \\
\downarrow p' & & \downarrow p \\
X & \xrightarrow{f} & Y
\end{array}
\]

where the homotopy fibers of \( f \) are 0-truncated and have finitely many homotopy groups. Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite products and coproducts. Using Lemma 6.1.6.3, it is not difficult to show that the natural transformation \( f_! \circ p'^* \to f'_! \circ p'^* \) determined by \( Nm_f' \) is homotopic to the composition

\[
f'_! \circ p'^* \to p^* \circ f_! \xrightarrow{Nm_f} p^* \circ f_* \to f'_* \circ p'^*.
\]

Example 6.1.6.11. Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite products and coproducts, let \( S \) be a finite set (regarded as a discrete simplicial set), and let \( f : S \to \Delta^0 \) be the canonical projection map. We can identify objects of \( \mathcal{C}^S \) with tuples \( C = (C_s \in \mathcal{C})_{s \in S} \). The norm map \( f_!(C) \to f_*(C) \) can be identified with the map

\[
\prod_{s \in S} C_s \to \prod_{t \in S} C_t,
\]

which classifies a collection of maps \( \phi_{s,t} : C_s \to C_t \) in \( \mathcal{C} \) where \( \phi_{s,t} = \text{id} \) if \( s = t \) and the zero map otherwise.
Proposition 6.1.6.12. Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite products and coproducts. The following conditions are equivalent:

1. For every map of Kan complexes \( f : X \to Y \) whose homotopy fibers are discrete and have finitely many connected components, the norm map \( \text{Nm}_f : f_! \to f_* \) is an equivalence.

2. Condition (1) holds whenever \( Y = \Delta^0 \).

3. For every finite collection of objects \( \{C_s \in \mathcal{C}\}_{s \in S} \), the map

\[
\prod_{s \in S} C_s \to \prod_{t \in S} C_t
\]

described in Example 6.1.6.11 is an equivalence.

Proof. The implication (1) \( \Rightarrow \) (2) is obvious and the converse follows from Remark 6.1.6.10. The equivalence of (2) and (3) follows from Example 6.1.6.11. \( \square \)

Definition 6.1.6.13. We will say that an \( \infty \)-category \( \mathcal{C} \) is semiadditive if it satisfies the equivalent conditions of Proposition 6.1.6.12.

Remark 6.1.6.14. Let \( \mathcal{C} \) be a semiadditive \( \infty \)-category. Suppose we are given a pair of objects \( C, D \in \mathcal{C} \) and a finite collection of maps \( \{\phi_s : C \to D\}_{s \in S} \). Then we can define a new map \( \phi : C \to D \) by the composition

\[
C \to \prod_{s \in S} C \xrightarrow{\phi_s \in S} \prod_{s \in S} D \cong \prod_{s \in S} D \to D,
\]

where the first map is the diagonal of \( C \) and the last the codiagonal of \( D \). This construction determines a map

\[
\prod_{s \in S} \text{Map}_\mathcal{C}(C, D) \to \text{Map}_\mathcal{C}(C, D),
\]

which endows \( \text{Map}_\mathcal{C}(C, D) \) with the structure of a commutative monoid up to homotopy. We will denote the image of a collection of morphisms \( \{\phi_s\}_{s \in S} \) by \( \sum_{s \in S} \phi_s \).

It is possible to make a much stronger assertion: the addition on \( \text{Map}_\mathcal{C}(C, D) \) is not only commutative and associative up to homotopy, but up to coherent homotopy. That is, each mapping space in \( \mathcal{C} \) can be regarded as a commutative algebra object of \( \mathcal{S} \), and the composition of morphisms in \( \mathcal{C} \) is multilinear. Since we do not need this for the time being, we omit the proof.

Remark 6.1.6.15. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite products and coproducts. Since products and coproducts in \( \mathcal{C} \) are also products and coproducts in the homotopy category \( h\mathcal{C} \), we see that \( \mathcal{C} \) is semiadditive if and only if (the nerve of) the category \( h\mathcal{C} \) is semiadditive.

Example 6.1.6.16. Let \( \mathcal{A} \) be an additive category (see Definition 1.1.2.1). Then the \( \infty \)-category \( N(\mathcal{A}) \) is semiadditive.

Example 6.1.6.17. Let \( \mathcal{C} \) be a stable \( \infty \)-category. Then the homotopy category \( h\mathcal{C} \) is additive (Lemma 1.1.2.10). Combining this with Example 6.1.6.16 and Remark 6.1.6.15, we deduce that \( \mathcal{C} \) is semiadditive.

Definition 6.1.6.18. Let \( X \) be a Kan complex. We will say that \( X \) is a finite groupoid if the following conditions are satisfied:

1. The set of connected components \( \pi_0 X \) is finite.

2. For every point \( x \in X \), the fundamental group \( \pi_1(X, x) \) is finite.

3. The homotopy groups \( \pi_n(X, x) \) vanish for \( n \geq 2 \).
More generally, we say that a map of Kan complexes \( f : X \to Y \) is a \textit{relative finite groupoid} if the homotopy fibers of \( f \) are finite groupoids.

**Construction 6.1.6.19.** Let \( \mathcal{C} \) be a semiadditive \( \infty \)-category which admits limits and colimits indexed by finite groupoids. It follows that for any map of Kan complexes \( f : X \to Y \) which is a relative finite groupoid, the pullback functor \( f^* : \mathcal{C}^Y \to \mathcal{C}^X \) admits left and right adjoints \( f_l \) and \( f_s \), given by left and right Kan extension along \( f \).

Let \( X \times_Y X \) denote the homotopy fiber product of \( X \) with itself over \( Y \) and let \( \delta : X \to X \times_Y X \) be the diagonal map. Since \( f \) is a relative finite groupoid, the homotopy fibers of \( \delta \) are homotopy equivalent to finite discrete spaces. Construction 6.1.6.19 determines a natural transformation \( \text{Nm} : \delta_l \to \delta_s \). Since \( \mathcal{C} \) is semiadditive, the natural transformation \( \text{Nm} \) is an equivalence and therefore admits a homotopy inverse \( \delta^{-1} : \delta_s \to \delta_l \).

Let \( p_0, p_1 : X \times_Y X \to X \) be the projection onto the first and second factor, respectively. We have a natural transformation of functors

\[
\begin{align*}
p_0^* & \to \delta_s \delta^* p_0^* \\
\delta^{-1} & \simeq \delta_l \simeq \delta_l \delta^* p_1^* \to p_1^*
\end{align*}
\]

which is adjoint to a natural transformation \( \beta : \text{id}_{\mathcal{C}^X} \to (p_0)_* p_1^* \). Since we have a homotopy pullback diagram

\[
\begin{array}{ccc}
X \times_Y X & \xrightarrow{p_0} & X \\
\downarrow f \downarrow & & \downarrow f \downarrow \\
X & \xrightarrow{f} & Y,
\end{array}
\]

Lemma 6.1.6.3 implies that the canonical map \( f^* f_* \to (p_0)_* p_1^* \) is an equivalence, so that \( \beta \) determines a map \( \text{id}_{\mathcal{C}^X} \to f^* f_* \), which is adjoint to a natural transformation \( \text{Nm}_f : f_l \to f_s \). We will refer to \( \text{Nm}_f \) as the \textit{norm map} determined by \( f \).

**Remark 6.1.6.20.** In the situation of Construction 6.1.6.19, assume that \( f \) is 0-truncated. Then the definition of \( \text{Nm}_f \) given in Construction 6.1.6.19 agrees with that given in Construction 6.1.6.8 (and, if \( f \) is \((-1\))-truncated, with that given in Construction 6.1.6.4): this follows easily from Remark 6.1.6.9.

**Remark 6.1.6.21.** In the situation of Construction 6.1.6.19, suppose we are given a homotopy pullback diagram

\[
\begin{array}{ccc}
X' & \xrightarrow{f'} & Y' \\
\downarrow p' \downarrow & & \downarrow p \downarrow \\
X & \xrightarrow{f} & Y.
\end{array}
\]

Using Lemma 6.1.6.3, we deduce that the natural transformation \( f_l' \circ p'^* \to f_s' \circ p'^* \) determined by \( \text{Nm}_{f'} \) is homotopic to the composition

\[
f_l' \circ p'^* \to p^* \circ f_l \xrightarrow{\text{Nm}_f} p^* \circ f_s \to f_s' \circ p'\text{.}
\]

**Example 6.1.6.22.** Let \( G \) be a finite group. Then the classifying space \( BG \) is a finite groupoid. Let \( f : BG \to \Delta^0 \) be the projection map. If \( \mathcal{C} \) is semiadditive \( \infty \)-category which admits limits and colimits indexed by finite groupoids, then Construction 6.1.6.19 determines a natural transformation \( \text{Nm}_f : f_l \to f_s \).

In particular, for every \( G \)-equivariant object \( M \in \mathcal{C} \), we obtain a canonical map \( \text{Nm} : M_G \to M^G \).

**Remark 6.1.6.23.** Let \( \mathcal{C} \) be a semiadditive \( \infty \)-category which admits limits and colimits indexed by finite groupoids, and let \( G \) be a finite group. Let \( M \) be a \( G \)-equivariant object of \( \mathcal{C} \), and abuse notation by identifying \( M \) with its image in \( \mathcal{C} \). We have canonical maps \( e : M \to M_G \) and \( e' : M^G \to M \). Unwinding the definitions, we see that the composition

\[
M \xrightarrow{e} M_G \xrightarrow{\text{Nm}} M^G \xrightarrow{e'} M
\]
is given by $\sum_{g \in G} \phi_g$, where for each $g \in G$ we let $\phi_g : M \to M$ be the map given by evaluation on the 1-simplex of $BG$ corresponding to $g$; here the sum is formed with respect to the addition described in Remark 6.1.6.14.

If $\mathcal{E}$ is equivalent to the nerve of an ordinary category, then the map $M \to MG$ is a categorical epimorphism and the map $MG \to M$ is a categorical monomorphism. It follows that the map $Nm : MG \to MG$ is determined (up to homotopy) by the formula $e' \circ N \circ e \simeq \sum_g \phi_g$. Moreover, the map $Nm$ exists by virtue of the observation that the map $\sum_g \phi_g : M \to M$ is invariant under left and right composition with the maps $\phi_g$.

**Definition 6.1.6.24.** Let $\mathcal{E}$ be a stable $\infty$-category which admits countable limits and colimits. Let $G$ be a finite group, and let $M$ be a $G$-equivariant object of $\mathcal{E}$. We will denote the cofiber of the norm map $Nm : MG \to MG$ by $M^G$. We refer to the formation $M \mapsto M^G$ as the Tate construction.

**Remark 6.1.6.25.** Let $\mathcal{E}$ be a semiadditive $\infty$-category which admits limits and colimits indexed by finite groupoids. Assume that for every finite group $G$ and every $G$-equivariant object $M$ of $\mathcal{E}$, the norm map $Nm : MG \to MG$ is an equivalence (if $\mathcal{E}$ is stable, this is equivalent to the requirement that the Tate construction $M^G$ vanish). It follows that for every relative finite groupoid $f : X \to Y$, the norm map $Nm_f : f_! \to f_*$ is an equivalence of functors from $\mathcal{E}^X$ to $\mathcal{E}^Y$. We can then repeat Construction 6.1.6.19 to define a norm map $Nm_f : f_! \to f_*$ for maps $f : X \to Y$ whose homotopy fibers are finite 2-groupoids. If $\mathcal{E}$ also admits limits and colimits indexed by finite 2-groupoids, then we can repeat Construction 6.1.6.19 to define a norm map $Nm_f : f_! \to f_*$ whenever $f$ is a relative finite 2-groupoid. This condition is satisfied, for example, if $\mathcal{E}$ is a $Q$-linear $\infty$-category (here $Q$ denotes the field of rational numbers), but is generally not satisfied for stable $\infty$-categories defined in positive or mixed characteristics. However, it is always satisfied in the setting of $K(n)$-local stable homotopy theory. We will study this construction in more detail in a future work.

**Example 6.1.6.26.** Let $\mathcal{E}$ be a semiadditive $\infty$-category which admits limits and colimits indexed by finite groupoids. Let $G$ be a finite group, let $i : \Delta^0 \to BG$ be the inclusion of the base point and let $f : BG \to \Delta^0$ be the projection map. Let $M \in \mathcal{E} \simeq \mathcal{E}^\Delta^0$ and let $N = i_M \in \mathcal{E}^{BG}$, so that $N = i_M \simeq \prod_{g \in G} M \simeq i_M$. Unwinding the definitions, we see that the norm map $f_!(N) \to f_*(N)$ is given by the composition

$$f_!(N) = f_! i_M \simeq (id_M) \simeq (id_M) \simeq f_* i_M \simeq f_*(N)$$

and is therefore an equivalence. If $\mathcal{E}$ is stable, we conclude that the Tate construction $N^G$ is a zero object of $\mathcal{E}$.

Let us now return to the calculus of functors. Suppose we are given a symmetric $n$-ary functor $F : \mathcal{E}^{(n)} \to \mathcal{D}$, where $\mathcal{D}$ is a stable $\infty$-category which admits countable limits and colimits. Restricting to the diagonal, $F$ determines a diagram $(F^0) : B\Sigma_n \to \text{Fun}(\mathcal{E}, \mathcal{D})$. Taking the colimit and limit of this diagram, we obtain functors $(F^0)_{\Sigma_n} : \mathcal{E} \to \mathcal{D}$, and a natural transformation $Nm : (F^0)_{\Sigma_n} \to (F^0)^{\Sigma_n}$. We will denote the cofiber of this natural transformation by $(F^0)^{\Sigma_n}$.

**Proposition 6.1.6.27.** Let $\mathcal{E}$ be an $\infty$-category which admits finite colimits and has a final object, and let $\mathcal{D}$ be a stable $\infty$-category which admits finite limits and colimits. Let $F \in \text{SymFun}_{\text{fin}}(\mathcal{E}, \mathcal{D})$. Then the functor $(F^0)^{\Sigma_n}$ is $(n-1)$-excisive.

**Proof.** The functor $(F^0)_{\Sigma_n}$ is $n$-homogeneous by Proposition 6.1.5.4. Since the collection of $n$-excisive functors from $\mathcal{E}$ to $\mathcal{D}$ is stable under countable limits, Proposition 6.1.3.4 implies that $(F^0)_{\Sigma_n}$ is $n$-excisive. It follows that $(F^0)^{\Sigma_n}$ is also $n$-excisive. Consequently, to prove that the cross effect $cr_n(F^0)^{\Sigma_n}$ vanishes (Proposition 6.1.4.10). Let $(F^0) : B\Sigma_n \to \text{Fun}(\mathcal{E}, \mathcal{D})$ be as above, so that $cr_n(F^0)$ determines a map $B\Sigma_n \to \text{Fun}(\mathcal{E}^n, \mathcal{D})$. This diagram has both a colimit and a limit, which we will denote by $(cr_n(F^0))^{\Sigma_n}$ and $(cr_n(F^0))^{\Sigma_n}$, respectively. Moreover, we have a transfer map

$$Nm : (cr_n(F^0))_{\Sigma_n} \to (cr_n(F^0))^{\Sigma_n}$$
whose cofiber is the cross-effect $cr_n(F \delta)^{\Sigma_n}$. It will therefore suffice to show that $Nm$ is an equivalence. In view of Example 6.1.6.26, it will suffice to show that the diagram $\text{cr}_n \circ (F \delta)$ is an induced representation of the symmetric group $\Sigma_n$: that is, that it is given by a left Kan extension along a map $\Delta^0 \to B\Sigma_n$. This follows immediately from Proposition 6.1.4.13.

\textbf{Remark 6.1.6.28.} Let $\mathcal{C}$ and $\mathcal{D}$ be stable $\infty$-categories, and assume that $\mathcal{D}$ admits countable limits and colimits. Suppose we are given a symmetric $n$-ary functor $F : \mathcal{C}^{(n)} \to \mathcal{D}$, and consider the fiber sequence

$$(F \delta)_{\Sigma_n} \to (F \delta)^{\Sigma_n} \to (F \delta)^{1\Sigma_n}$$

constructed above. Proposition 6.1.4.14 implies that $(F \delta)_{\Sigma_n}$ is $n$-homogeneous: that is, it is $n$-excisive and $\text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}((F \delta)_{\Sigma_n}, G)$ is contractible for every $(n - 1)$-excisive functor $G : \mathcal{C} \to \mathcal{D}$. Replacing $\mathcal{C}$ and $\mathcal{D}$ by their opposite $\infty$-categories (which does not change the notion of $k$-excisive functor; see Corollary 6.1.1.17), the same argument shows that $(F \delta)^{\Sigma_n}$ is $n$-cohomogeneous: that is, it is $n$-excisive and the mapping space $\text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(G, (F \delta)^{\Sigma_n})$ is contractible whenever $G$ is $(n - 1)$-excisive. It follows that for any $(n - 1)$-excisive functor $G$, the canonical map

$$\text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(G, (F \delta)^{\Sigma_n}) \to \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(G, (F \delta)_{\Sigma_n}[-1])$$

is a homotopy equivalence.

\textbf{Remark 6.1.6.29.} Let $\mathcal{C}$ and $\mathcal{D}$ be stable $\infty$-categories, let $n > 0$ be an integer, and assume that $\mathcal{D}$ admits countable limits and colimits. Combining Remark 6.1.6.28, Proposition 6.1.6.27, and Theorem 6.1.2.5, we deduce that giving a reduced $(n - 1)$-excisive functor $F : \mathcal{C} \to \mathcal{D}$ is equivalent to giving the following data:

(a) A reduced $(n - 1)$-excisive $E : \mathcal{C} \to \mathcal{D}$ (which will be given by $P_{n-1}(F)$).

(b) A functor $K \in \text{SymFun}_{(n)}^{(n)}(\mathcal{C}, \mathcal{D})$ (which is a preimage of $\text{fib}(F \to P_{n-1}F)$ under the equivalence of Proposition 6.1.4.14).

(c) A natural transformation of $(n - 1)$-excisive functors $\alpha : E \to (K \delta)^{\Sigma_n}$ (which is equivalent to the data of a map $E \to (K \delta)_{\Sigma_n}[-1]$, by Remark 6.1.6.28).

From the data of (a), (b), and (c), we can recover an $n$-excisive functor $F$ by taking the fiber of the composite map $E \Rightarrow (K \delta)^{\Sigma_n} \to (K \delta)_{\Sigma_n}[-1]$, which can also be described as the fiber product

$$E \times_{(K \delta)^{\Sigma_n}} (K \delta)_{\Sigma_n}.$$ 

\subsection{Differentiation}

Let $\mathcal{C}$ be an $\infty$-category which admits finite limits. In §1.4.2, we introduced the stable $\infty$-category $\text{Sp}(\mathcal{C})$ of spectrum objects of $\mathcal{C}$. In this section, we will discuss the extent to which the construction $\mathcal{C} \mapsto \text{Sp}(\mathcal{C})$ is functorial in $\mathcal{C}$. For example, suppose that $F : \mathcal{C} \to \mathcal{D}$ is a functor between $\infty$-categories which admits finite limits. Under what conditions does $F$ determine a functor from $\text{Sp}(\mathcal{C})$ to $\text{Sp}(\mathcal{D})$? The most obvious case to consider is when the functor $F$ is left exact. In this case, pointwise composition with $F$ determines a functor $\partial F : \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{D})$. This functor $f$ fits into a commutative diagram

$$
\begin{array}{ccc}
\text{Sp}(\mathcal{C}) & \overset{\partial F}{\longrightarrow} & \text{Sp}(\mathcal{D}) \\
\downarrow^{\Omega^\infty} & & \downarrow^{\Omega^\infty} \\
\mathcal{C} & \overset{F}{\longrightarrow} & \mathcal{D}.
\end{array}
$$

There is a dual situation which is also important. Suppose $\mathcal{C}$ and $\mathcal{D}$ are presentable $\infty$-categories, and that the functor $F$ preserves small colimits. Applying Corollary T.5.5.2.9, we deduce that $F$ admits a
right adjoint $G$. Since $G$ is left exact, we can apply the above reasoning to obtain an induced functor $\partial G : \text{Sp}(\mathcal{D}) \to \text{Sp}(\mathcal{C})$. We can use Corollary T.5.5.2.9 again to deduce that $\partial G$ admits a left adjoint $\partial F$. This left adjoint fits into a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\text{Sp}(\mathcal{C}) & \xrightarrow{\partial F} & \text{Sp}(\mathcal{D}) \\
\sigma^\infty_+ & \downarrow & \sigma^\infty_+ \\
\mathcal{C} & \xrightarrow{F} & \mathcal{D}.
\end{array}
$$

This raises a number of questions. For example, suppose that a functor $F : \mathcal{C} \to \mathcal{D}$ preserves small colimits and finite limits. In this case, we can apply either of the above constructions to produce a functor $\text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{D})$: do the resulting functors coincide (up to homotopy)? On the other hand, suppose that $F$ satisfies neither condition; can one still hope to find an exact functor $\partial F : \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{D})$ which is somehow related to $F$?

To address these questions, it is convenient to reformulate them in terms that do not mention spectrum objects at all. Let $\mathcal{C}$ and $\mathcal{D}$ be presentable pointed $\infty$-categories. Composition with the functors $\sigma^\infty_+ : \mathcal{C} \to \text{Sp}(\mathcal{C})$ and $\Omega_+^\infty : \text{Sp}(\mathcal{D}) \to \mathcal{D}$ determines a forgetful functor $\theta : \text{Fun}(\text{Sp}(\mathcal{C}), \text{Sp}(\mathcal{D})) \to \text{Fun}(\mathcal{C}, \mathcal{D})$, where $\text{Fun}^l(\text{Sp}(\mathcal{C}), \text{Sp}(\mathcal{D}))$ denotes the $\infty$-category of colimit-preserving functors from $\text{Sp}(\mathcal{C})$ to $\text{Sp}(\mathcal{D})$ (that is, the $\infty$-category of exact functors which preserve filtered colimits). Under mild assumptions on $\mathcal{D}$, the functor $\theta$ is fully faithful, and its essential image is a full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those reduced, excisive functors which preserve filtered colimits. Consequently, we may rephrase our problem as follows: given a functor $F : \mathcal{C} \to \mathcal{D}$, can we choose a reduced, excisive functor $F' : \mathcal{C} \to \mathcal{D}$ which preserves filtered colimits and is, in some sense, a best approximation to the original functor $F$?

These questions can be readily addressed using ideas introduced in §6.1. Let us suppose that $F : \mathcal{C} \to \mathcal{D}$ is a reduced functor between compactly generated pointed $\infty$-categories, which preserves small filtered colimits. According to Theorem 6.1.1.10, there exists a natural transformation $\alpha : F \to P_1 F$, which is universal among natural transformations from $F$ to an excisive functor. Corollary 6.1.2.9 implies that $P_1 F$ is given by the composition

$$
\mathcal{C} \xrightarrow{f} \text{Sp}(\mathcal{D}) \xrightarrow{\Omega^\infty_+} \mathcal{D},
$$

where $f$ is reduced and excisive (and therefore right exact). The functor $P_1 F$ preserves small filtered colimits (Remark 6.1.31), so that $f$ preserves small filtered colimits and therefore all small colimits. It follows from Corollary 1.4.4.5 that the functor $f$ factors as a composition

$$
\mathcal{C} \xrightarrow{\sigma^\infty_+} \text{Sp}(\mathcal{C}) \xrightarrow{\partial(F)} \text{Sp}(\mathcal{D}),
$$

where $\partial(F)$ is an exact functor between stable $\infty$-categories. We can then regard $\alpha$ as a natural transformation from $F$ to $\Omega^\infty_+ \circ \partial F \circ \sigma^\infty_+$. We will refer to the functor $\partial(F)$ as the derivative of $F$.

Our first objective in this section is to study the passage from $F$ to $\partial(F)$. In §6.2.1, we will give a concrete description of $\partial(F)$, analogous to the formula $P_1 F \simeq \lim_\leftarrow \Omega^\infty_+ \circ \sigma^\infty_+ \circ F$ of Example 6.1.28. As an application, we prove a version of the Klein-Rognes chain rule, which asserts that if $G : \mathcal{D} \to \mathcal{E}$ is another reduced functor between compactly generated pointed $\infty$-categories which commutes with filtered colimits, then there is a canonical equivalence $\partial(G \circ F) \simeq \partial(G) \circ \partial(F)$ of functors from $\text{Sp}(\mathcal{E})$ to $\text{Sp}(\mathcal{C})$ (see Theorem 6.2.1.22 and Corollary 6.2.1.24). We can informally summarize the situation informally as follows: there is a functor of $\infty$-categories which carries each compactly generated pointed $\infty$-category $\mathcal{C}$ to the stable $\infty$-category $\text{Sp}(\mathcal{C})$, and to each reduced functor $F : \mathcal{C} \to \mathcal{D}$ which commutes with filtered colimits its derivative $\partial(F)$. In §6.2.2, we will give a precise formulation and proof of this assertion (Theorem 6.2.2.1), using the a relative version of the stabilization construction $\mathcal{C} \mapsto \text{Sp}(\mathcal{C})$ (see Construction 6.2.2.2).

In §6.2.3, we will study the inclusion $\text{Exc}_\infty(\mathcal{C}, \mathcal{D}) \hookrightarrow \text{Fun}(\mathcal{C}, \mathcal{D})$. Under some mild hypotheses, we show that this functor admits a left adjoint, which carries a functor $F : \mathcal{C} \to \mathcal{D}$ to its differential $DF : \mathcal{C} \to \mathcal{D}$. If $F$ is reduced, then $DF$ can be identified with the 1-excisive approximation $P_1(F)$ introduced in §6.1.1.
6.2. DIFFERENTIATION

In the general case, we have $DF \simeq P_1(\text{cored}(F))$, where the coreduction of $F$ is given by the formula $\text{cored}(F)(C) = \text{cofib}(F(\ast) \rightarrow F(C))$. Our main result is that there is a close connection between the derivative $\partial(F)$ and the differential $DF$ for a large class of (possibly nonreduced) functors $F$ (Corollary 6.2.3.24).

Throughout this section, we will study differentiation not only for one-variable functors $F : \mathcal{C} \rightarrow \mathcal{D}$, but also for multifunctors $F : \prod_{s \in S} \mathcal{C}_s \rightarrow \mathcal{D}$. One motivation for this generality is that it gives a new perspective on the smash product monoidal structure on spectra constructed in §4.8.2: for each $n \geq 0$, the iterated smash product functor $\otimes : \text{Sp}^n \rightarrow \text{Sp}$ can be identified with the derivative of the iterated Cartesian product functor $\times : S^n \rightarrow S$. In §6.2.4, we will use this observation to obtain a generalization of the smash product to $\text{Sp}(\mathcal{C})$, where $\mathcal{C}$ is an arbitrary compactly generated ∞-category. This generalization will play an important role in our discussion of the chain rule in §6.3. To construct it, we will need to generalize the stabilization construction of §6.2.2 to the case of multifunctors. Our treatment of this generalization is somewhat technical; we give the construction in §6.2.5, and characterize the result by a universal property in §6.2.6.

### 6.2.1 Derivatives of Functors

Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between ∞-categories which admit finite limits. We will define the derivative of $F$ to be an exact functor $\text{Sp}(\mathcal{C}) \rightarrow \text{Sp}(\mathcal{D})$ which is, in some sense, the best possible “linear” approximation to $f$. For later applications, we give a definition in the setting of functors of several variables.

**Definition 6.2.1.1.** Let $\{\mathcal{C}_s\}_{s \in S}$ be a finite collection of ∞-categories which admit finite limits, $\mathcal{D}$ an ∞-category which admits finite limits, and suppose we are given functors

$$F : \prod_{s \in S} \mathcal{C}_s \rightarrow \mathcal{D} \quad f : \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \rightarrow \text{Sp}(\mathcal{D}).$$

We will say that a natural transformation

$$\alpha : F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \rightarrow \Omega^\infty_{\mathcal{D}} \circ f$$

exhibits $f$ as a derivative of $F$ if the following conditions are satisfied:

1. The functor $f$ is multilinear (that is, it is exact in each variable).
2. For every multilinear functor $g : \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \rightarrow \text{Sp}(\mathcal{D})$, composition with $\alpha$ induces a homotopy equivalence

$$\text{Map}_{\text{Fun}}(\prod_{s \in S} \text{Sp}(\mathcal{C}_s), \text{Sp}(\mathcal{D}))(f, g) \rightarrow \text{Map}_{\text{Fun}}(\prod_{s \in S} \text{Sp}(\mathcal{C}_s), \mathcal{D})(F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s}, \Omega^\infty_{\mathcal{D}} \circ g).$$

**Notation 6.2.1.2.** Let $F : \prod_{s \in S} \mathcal{C}_s \rightarrow \mathcal{D}$ be as in Definition 6.2.1.1. If there exists a natural transformation $\alpha : F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \rightarrow \Omega^\infty_{\mathcal{D}} \circ f$ which exhibits $f$ as a derivative of $F$, then $f$ is determined by $F$, up to canonical equivalence. We will emphasize the dependence of $F$ on $f$ by writing $f$ as $\partial F$. In the special case where $S$ has a single element, we will denote $f$ simply by $\partial F$.

**Warning 6.2.1.3.** The derivative $\partial$ of a functor $F : \prod_{s \in S} \mathcal{C}_s \rightarrow \mathcal{D}$ depends not only on $F$, but also on the product decomposition of $\prod_{s \in S} \mathcal{C}_s$. For example, the derivative $\partial F$ is generally quite different from the functor $\partial F$, obtained by viewing $F$ as a functor of one variable from $\mathcal{C} = \prod_{s \in S} \mathcal{C}_s$ into $\mathcal{D}$.

**Example 6.2.1.4.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a left exact functor between ∞-categories which admit finite limits. Then composition with $F$ induces a functor $f : \text{Sp}(\mathcal{C}) \rightarrow \text{Sp}(\mathcal{D})$, and we have an evident equivalence
Example 6.2.1.5. In the situation of Definition 6.2.1.1, suppose that \( S \) is empty, so that we can identify a functor \( F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D} \) with an object \( D \in \mathcal{D} \) and a functor \( f : \prod_{s \in S} \operatorname{Sp}(\mathcal{C}_s) \to \operatorname{Sp}(\mathcal{D}) \) with an object \( X \in \operatorname{Sp}(\mathcal{D}) \). A morphism \( \alpha : D \to \Omega^\infty_{\mathcal{D}}(X) \) exhibits \( f \) as a derivative of \( F \) if and only if it has the following universal property: for every spectrum object \( Y \in \operatorname{Sp}(\mathcal{D}) \), composition with \( \alpha \) induces a homotopy equivalence

\[
\operatorname{Map}_{\operatorname{Sp}(\mathcal{D})}(X, Y) \to \operatorname{Map}_{\mathcal{D}}(D, \Omega^\infty_{\mathcal{D}} Y).
\]

The requirement that every functor \( \prod_{s \in S} \mathcal{C}_s \to \mathcal{D} \) admits a derivative is then equivalent to the requirement that the functor \( \Omega^\infty_{\mathcal{D}} : \operatorname{Sp}(\mathcal{D}) \to \mathcal{D} \) admits a left adjoint \( \Sigma^\infty_{\mathcal{D}} : \mathcal{D} \to \operatorname{Sp}(\mathcal{D}) \).

Remark 6.2.1.6. Let \( \{ \mathcal{C}_s \}_{s \in S} \) be a finite collection of \( \infty \)-categories which admit finite limits, \( \mathcal{D} \) an \( \infty \)-category which admits finite limits, and \( F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D} \) a functor. For each \( s \in S \), let \( \mathcal{C}_{s,*} \) denote the \( \infty \)-category of pointed objects of \( \mathcal{C}_s \), so that the forgetful functor \( \mathcal{C}_{s,*} \to \mathcal{C}_s \) induces an equivalence of \( \infty \)-categories \( u_s : \operatorname{Sp}(\mathcal{C}_{s,*}) \to \operatorname{Sp}(\mathcal{C}_s) \) (Remark 1.4.2.18). Let \( F_* \) denote the composite map

\[
\prod_{s \in S} \mathcal{C}_{s,*} \to \prod_{s \in S} \mathcal{C}_s \xrightarrow{F} \mathcal{D},
\]

and let \( u \) be the product of the functors \( u_s \). Then a natural transformation \( \alpha : F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \to \Omega^\infty_{\mathcal{D}} \circ f \) exhibits \( f \) as a derivative of \( F \) if and only if the induced transformation

\[
F_* \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_{s,*}} \to \Omega^\infty_{\mathcal{D}} \circ f \circ u
\]

exhibits \( f \circ u \) as a derivative of \( F_* \).

Remark 6.2.1.7. Let \( \{ \mathcal{C}_s \}_{s \in S} \) be finite collection of \( \infty \)-categories which admit finite limits, let \( \mathcal{D} \) be an \( \infty \)-category which admits finite limits so that we have a commutative diagram

\[
\begin{array}{ccc}
\operatorname{Sp}(\mathcal{D}_s) & \xrightarrow{u} & \operatorname{Sp}(\mathcal{D}) \\
\downarrow & & \downarrow \circ \\
\mathcal{D}_s & \xrightarrow{v} & \mathcal{D}.
\end{array}
\]

Suppose we are given functors

\[
F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}_s \quad f : \prod_{s \in S} \operatorname{Sp}(\mathcal{C}_s) \to \operatorname{Sp}(\mathcal{D}_s).
\]

For any functor \( g : \prod_{s \in S} \operatorname{Sp}(\mathcal{C}_s) \to \operatorname{Sp}(\mathcal{D}_s) \) which preserves final objects, the canonical maps

\[
\operatorname{Map}_{\operatorname{Fun}[\prod_{s \in S} \operatorname{Sp}(\mathcal{C}_s), \mathcal{D}_s]}(F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s}, \Omega^\infty_{\mathcal{D}_s} \circ g) \to \operatorname{Map}_{\operatorname{Fun}[\prod_{s \in S} \operatorname{Sp}(\mathcal{C}_s), \mathcal{D}_s]}(v \circ F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s}, \Omega^\infty_{\mathcal{D}_s} \circ u \circ g)
\]

and

\[
\operatorname{Map}_{\operatorname{Fun}[\prod_{s \in S} \operatorname{Sp}(\mathcal{C}_s), \mathcal{D}_s]}(\Omega^\infty_{\mathcal{D}_s} \circ f, \Omega^\infty_{\mathcal{D}_s} \circ g) \to \operatorname{Map}_{\operatorname{Fun}[\prod_{s \in S} \operatorname{Sp}(\mathcal{C}_s), \mathcal{D}_s]}(\Omega^\infty_{\mathcal{D}_s} \circ u \circ f, \Omega^\infty_{\mathcal{D}_s} \circ u \circ g).
\]

If \( S \) is nonempty, then any multilinear functor \( g \) preserves final objects. It follows that a natural transformation \( \alpha : F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \to \Omega^\infty_{\mathcal{D}_s} \circ f \) exhibits \( f \) as a derivative of \( F \) if and only if it exhibits \( u \circ f \) as a derivative of \( v \circ f \).
6.2. DIFFERENTIATION

Remark 6.2.1.8. Let \( \{ \mathcal{C}_s \}_{s \in S} \) be a nonempty finite collection of pointed \( \infty \)-categories which admit finite limits, and let \( \mathcal{D} \) be another \( \infty \)-category which admits finite limits. Repeatedly applying Proposition 1.4.2.22, we see that composition with \( \Omega^\infty_{\mathcal{D}} \) induces an equivalence of \( \infty \)-categories

\[
\text{Exc}_s(\prod_{s \in S} \mathcal{C}_s, \text{Sp}(\mathcal{D})) \to \text{Exc}_s(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}).
\]

Consequently, condition (2) of Definition 6.2.1.1 is equivalent to the following:

(2') For every multilinear functor \( F : \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \to \mathcal{D} \), composition with \( \alpha \) induces a homotopy equivalence

\[
\text{Map}_\text{Fun}(\prod_{s \in S} \text{Sp}(\mathcal{C}_s), \mathcal{D})(\Omega^\infty_{\mathcal{D}} \circ f, g) \to \text{Map}_\text{Fun}(\prod_{s \in S} \text{Sp}(\mathcal{C}_s), \mathcal{D})(F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s}, G).
\]

We have the following basic existence result for derivatives:

Proposition 6.2.1.9. Let \( \{ \mathcal{C}_s \}_{s \in S} \) be a nonempty finite collection of \( \infty \)-categories which admit finite colimits, \( \mathcal{D} \) a differentiable \( \infty \)-category, and \( F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D} \) a functor which is reduced in each variable. Then \( F \) admits a derivative \( \bar{\partial} F : \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \to \text{Sp}(\mathcal{D}) \).

Proof. Let \( P_1 : \text{Fun}(\prod_{s \in S} \text{Sp}(\mathcal{C}_s), \mathcal{D}) \to \text{Exc}_s(\prod_{s \in S} \text{Sp}(\mathcal{C}_s), \mathcal{D}) \) be a left adjoint to the inclusion (obtained by iterated application of Theorem 6.1.1.10), and let \( F' = P_1(F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s}) \). Then \( F' \) is multilinear, so Proposition 1.4.2.22 implies that \( F' = \Omega^\infty_{\mathcal{D}} \circ f \) for some multilinear functor \( f : \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \to \text{Sp}(\mathcal{D}) \). It follows from Remark 6.2.1.8 that the canonical map

\[
F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \to F' \simeq \Omega^\infty_{\mathcal{D}} \circ f
\]

exhibits \( f \) as a derivative of \( F \).

Our next goal is to obtain a more explicit construction for the derivative \( \bar{\partial} F \) of a reduced functor \( F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D} \). This will require a brief digression.

Notation 6.2.1.10. Let \( \mathcal{S}_* \) denote the \( \infty \)-category of pointed spaces. According to Remark 4.8.2.14, the smash product functor \( (X, Y) \to X \wedge Y \) endows a symmetric monoidal structure on \( \mathcal{S}_* \), which is characterized up to equivalence by the requirement that \( S^0 \in \mathcal{S}_* \) is the unit object and the smash product preserves small colimits separately in each variable. The full subcategory \( \mathcal{S}_*^{\text{fin}} \subseteq \mathcal{S}_* \) contains the unit object and is closed under smash products, and therefore inherits a symmetric monoidal structure from \( \mathcal{S}_* \). In particular, for every finite set \( S \), the iterated smash product determines a functor

\[
\wedge : \prod_{s \in S} \mathcal{S}_*^{\text{fin}} \to \mathcal{S}_*^{\text{fin}}.
\]

Proposition 6.2.1.11. Let \( T \) be a nonempty finite set, and let \( \mathcal{C} \) be an \( \infty \)-category which admits finite limits. Then composition with the smash product functor \( \wedge : \prod_{t \in T} \mathcal{S}_*^{\text{fin}} \to \mathcal{S}_*^{\text{fin}} \) induces an equivalence of \( \infty \)-categories

\[
\theta : \text{Sp}(\mathcal{C}) = \text{Exc}_s(\mathcal{S}_*^{\text{fin}}, \mathcal{C}) \to \text{Exc}_s(\prod_{t \in T} \mathcal{S}_*^{\text{fin}}, \mathcal{C}).
\]

Proof. Choose an element \( s \in T \), and let \( u : \mathcal{S}_*^{\text{fin}} \to \prod_{t \in T} \mathcal{S}_*^{\text{fin}} \) be the functor which is the identity on the \( s \)-th component, and takes the value \( S^0 \) on all other components. Composition with \( u \) induces a functor \( \theta' : \text{Exc}_s(\prod_{t \in T} \mathcal{S}_*^{\text{fin}}, \mathcal{C}) \to \text{Exc}_s(\mathcal{S}_*^{\text{fin}}, \mathcal{C}) = \text{Sp}(\mathcal{C}) \). The composite functor

\[
\mathcal{S}_*^{\text{fin}} \to \prod_{t \in T} \mathcal{S}_*^{\text{fin}} \xrightarrow{\theta'} \mathcal{S}_*^{\text{fin}}
\]

is equivalent to the identity, so that \( \theta' \circ \theta \) is an equivalence of \( \infty \)-categories. To prove that \( \theta \) is an equivalence of \( \infty \)-categories, it will suffice to prove that \( \theta' \) is an equivalence of \( \infty \)-categories. This follows by repeated application of Proposition 1.4.2.21.
Corollary 6.2.1.12. Let $T$ be a nonempty finite set and let $\mathcal{C}$ be a differentiable $\infty$-category. Then composition with the smash product functor $\land : \prod_{t \in T} S^\infty_{s_t} \to S^\infty_s$ induces a fully faithful embedding $\text{Sp}(\mathcal{C}) \to \text{Fun}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{C})$, which admits a left adjoint $L^T_\mathcal{C}$.

Proof. Proposition 6.2.1.11 implies that the functor $\text{Sp}(\mathcal{C}) \to \text{Fun}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{C})$ is a fully faithful embedding whose essential image is $\text{Exc}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{C})$. It will therefore suffice to show that the inclusion

$$\text{Exc}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{C}) \hookrightarrow \text{Fun}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{C})$$

admits a left adjoint. This left adjoint is given by the functor $P(1,...,1)$ of Proposition 6.1.3.6. \qed

Remark 6.2.1.13. Let $\mathcal{C}$ be a differentiable $\infty$-category, let $T$ be a nonempty set, and let

$$L^T_\mathcal{C} : \text{Fun}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{C}) \to \text{Sp}(\mathcal{C})$$

be as in Corollary 6.2.1.12. Let $Z_{\geq 0}^T$ be the collection of all finite sequences of natural numbers $\{n_t \in Z_{\geq 0}\}_{t \in T}$, and for $\bar{n} \in Z_{\geq 0}^T$ let $|\bar{n}| = \sum_{t \in T} n_t$. Using Example 6.1.1.28 and the proof of Proposition 6.2.1.11, we see that $\Omega^\infty \circ L^T_\mathcal{C}$ can be described explicitly by the formula

$$\Omega^\infty(L^T_\mathcal{C}F) = \lim_{\bar{n} \in Z_{\geq 0}^T} \Omega^{|\bar{n}|}F(\{S^{n_t}\}_{t \in T}) \in \mathcal{C}.$$  

Construction 6.2.1.14. Let $q : S \to T$ be a surjection of nonempty finite sets. For each $t \in T$, we let $S_t = q^{-1}\{t\} \subseteq S$ denote the inverse image of $t$ under the map $q$. Let $\{\mathcal{C}_t\}_{t \in T}$ be a collection of $\infty$-categories which admit finite limits and let $\mathcal{D}$ be a differentiable $\infty$-category. For every reduced functor $F : \prod_{t \in T} \mathcal{C}_t \to \mathcal{D}$, we let $F^+ : \prod_{t \in T} \text{Fun}_*(\prod_{s \in S_t} S^\infty_{s_t}, \mathcal{C}_t) \to \text{Fun}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{D})$ denote the functor which carries a collection of functors $\{X_t : \prod_{s \in S_t} S^\infty_{s_t} \to \mathcal{C}_t\}_{t \in T}$ to the composite functor

$$\prod_{s \in S} S^\infty_{s_t}(X_t) = \prod_{t \in T} \prod_{s \in S_t} S^\infty_{s_t} \to \prod_{t \in T} \mathcal{C}_t \to \mathcal{D}.$$  

We let $F' : \prod_{t \in T} \text{Sp}(\mathcal{C}_t) \to \text{Sp}(\mathcal{D})$ denote the functor given by the composition

$$\prod_{t \in T} \text{Sp}(\mathcal{C}_t) \to \prod_{t \in T} \text{Fun}_*(\prod_{s \in S_t} S^\infty_{s_t}, \mathcal{C}_t) \xrightarrow{F^+} \text{Fun}_*(\prod_{t \in T} S^\infty_{s_t}, \mathcal{D}) \xrightarrow{L^T_\mathcal{D}} \text{Sp}(\mathcal{D}),$$

where $L^T_\mathcal{D}$ is defined as in Corollary 6.2.1.12.

Note that the notation of Construction 6.2.1.14 is somewhat abusive: the functor $F^+$ depends not only on the functor $F$, but also on a choice of surjective map $q : S \to T$. However, this ambiguity is mostly harmless: under some mild assumptions, we will show that the functor $F'$ is a derivative of $F$ (Proposition 6.2.1.19), and therefore canonically independent of $q$.

Remark 6.2.1.15. Let $\mathcal{J}$ be a filtered $\infty$-category with only countably many simplices. Then there exists a left cofinal map $N(Z_{\geq 0}) \to \mathcal{J}$. To prove this, we first invoke Proposition T.5.3.1.16 to choose a left cofinal map $N(A) \to \mathcal{J}$, where $A$ is a filtered partially ordered; note that the proof of Proposition T.5.3.1.16 produces a countable partially ordered set $A$ in the case where $\mathcal{C}$ has only countably many simplices. Let $A = \{a_0, a_1, a_2, \ldots\}$. Let $b_0 = a_0$, and for each $n > 1$ choose an element $b_n \in A$ which is an upper bound for the set $\{b_{n-1}, a_n\}$. The sequence $b_0 \leq b_1 \leq b_2 \leq \ldots$ determines a map $N(Z_{\geq 0}) \to N(A)$; Theorem T.4.1.3.1 implies that this map is left cofinal.

Remark 6.2.1.16. Using Remark 6.2.1.15, we deduce the following:
(1) Let $\mathcal{C}$ be an $\infty$-category. Then $\mathcal{C}$ admits countable filtered colimits if and only if it admits sequential colimits. (In particular, if $\mathcal{C}$ also admits finite colimits and sequential colimits, then $\mathcal{C}$ admits all countable colimits.)

(2) Let $F : \mathcal{C} \to \mathcal{D}$ be a functor where the $\infty$-category $\mathcal{C}$ satisfies the equivalent conditions of (1). Then $F$ preserves countable filtered colimits if and only if $F$ preserves sequential colimits.

**Example 6.2.1.17.** Let $\mathcal{C}$ be a differentiable $\infty$-category. Then $\mathcal{C}$ admits sequential colimits, so that $\text{Fun}(\mathcal{S}^\text{fin}_*, \mathcal{C})$ also admits sequential colimits. Since sequential colimits in $\mathcal{C}$ are left exact, the full subcategory $\text{Sp}(\mathcal{C}) \subseteq \text{Fun}(\mathcal{S}^\text{fin}_*, \mathcal{C})$ is closed under sequential colimits. It follows from Remark 6.2.1.16 that $\text{Sp}(\mathcal{C})$ admits countable filtered colimits, and that the forgetful functor $\Omega^\infty : \text{Sp}(\mathcal{C}) \to \mathcal{C}$ preserves countable filtered colimits. Since $\text{Sp}(\mathcal{C})$ is a stable $\infty$-category (Corollary 1.4.2.17), it admits finite colimits. It follows that $\text{Sp}(\mathcal{C})$ admits all countable colimits (Proposition T.4.4.3.2). If $\mathcal{D}$ is another differentiable $\infty$-category, then a functor $F : \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{D})$ preserves countable colimits if and only if it is exact (that is, it preserves finite colimits) and preserves sequential colimits.

**Proposition 6.2.1.18.** Let $\{\mathcal{C}_t\}_{t \in T}$ be a nonempty finite collection of differentiable $\infty$-categories, let $\mathcal{D}$ be a differentiable $\infty$-category, and let $F : \prod_{t \in T} \mathcal{C}_t \to \mathcal{D}$ be a functor which is reduced in each variable and preserves sequential colimits. For every surjection $q : S \to T$ of finite sets, the functor $F^q : \prod_{t \in T} \text{Sp}(\mathcal{C}_t) \to \text{Sp}(\mathcal{D})$ of Construction 6.2.1.14 preserves countable colimits separately in each variable. In particular, $F^q$ is multilinear.

**Proof.** The functor $F^q$ is given by a composition

$$
\prod_{t \in T} \text{Sp}(\mathcal{C}_t) \xrightarrow{i} \prod_{t \in T} \text{Fun}_*(\prod_{s \in S_t} \mathcal{S}^\text{fin}_*, \mathcal{C}_t) \xrightarrow{F^q} \text{Fun}_*(\prod_{t \in T} \mathcal{S}^\text{fin}_*, \mathcal{D}) \xrightarrow{L^T} \text{Sp}(\mathcal{D}).
$$

The functor $i$ preserves sequential colimits since $\text{Exc}_*(\prod_{s \in S_t} \mathcal{S}^\text{fin}_*, \mathcal{C}_t)$ is closed under sequential colimits in $\text{Fun}_*(\prod_{s \in S_t} \mathcal{S}^\text{fin}_*, \mathcal{C}_t)$ (because sequential colimits in $\mathcal{C}$ are left exact). The functor $F^q$ preserves sequential colimits because $F$ does, and the functor $L^T$ preserves sequential colimits because it is a left adjoint. It follows that $F^q$ preserves sequential colimits.

To complete the proof, it will suffice to show that the functor $F^q$ is exact in each variable (Example 6.2.1.17). Fix an element $t_0 \in T$ and spectrum objects $\{Y_t \in \text{Sp}(\mathcal{C}_t)\}_{t \in T - \{t_0\}}$, and let $G : \text{Sp}(\mathcal{C}_{t_0}) \to \text{Sp}(\mathcal{D})$ be the functor given by the formula $G(X) = F^q(X, \{Y_t\}_{t \in T - \{t_0\}})$. We wish to show that $G$ is exact. In view of Corollary 1.4.2.14, it will suffice to show that for every object $X \in \text{Sp}(\mathcal{C}_{t_0})$, the canonical map $\nu : \Sigma_{\text{Sp}(\mathcal{D})} G(X) \to G(\Sigma_{\text{Sp}(\mathcal{C})} X)$ is an equivalence in $\text{Sp}(\mathcal{D})$. Note that $\Sigma_{\text{Sp}(\mathcal{C})} X \simeq X \circ \Sigma_{\mathcal{S}^\text{fin}_*}$. Choose an element $s_0 \in S$ such that $q(s) = t_0$, and let $U : \prod_{s \in S} \mathcal{S}^\text{fin}_* \to \prod_{s \in S} \mathcal{S}^\text{fin}_*$ be the functor given by the suspension on the $s_0$th coordinate, and the identity on the remaining coordinates. Then composition with $U$ induces a functor from $\text{Exc}_*(\prod_{s \in S} \mathcal{S}^\text{fin}_*, \mathcal{D})$ to itself, which fits into a commutative diagram

$$
\begin{align*}
\text{Sp}(\mathcal{D}) & \xrightarrow{\Sigma_{\text{Sp}(\mathcal{D})}} \text{Sp}(\mathcal{D}) \\
\text{Exc}_*(\prod_{s \in S} \mathcal{S}^\text{fin}_*, \mathcal{D}) & \xrightarrow{\circ U} \text{Exc}_*(\prod_{s \in S} \mathcal{S}^\text{fin}_*, \mathcal{D})
\end{align*}
$$

where the vertical maps are given by the equivalence of Proposition 6.2.1.11. Let $Z : \prod_{s \in S} \mathcal{S}^\text{fin}_* \to \mathcal{D}$ be the functor given by the composition

$$
\prod_{s \in S} \mathcal{S}^\text{fin}_* \simeq \prod_{t \in T} \left( \prod_{s \in S_t} \mathcal{S}^\text{fin}_* \right) \widehat{\times}_{\text{Sp}(\mathcal{C})} \prod_{t \in T} \mathcal{S}^\text{fin}_* \xrightarrow{X, (Y_t)} \prod_{t \in T} \mathcal{C}_t \xrightarrow{F} \mathcal{D},
$$

and let $P_{\bar{1}} : \text{Fun}_*(\prod_{s \in S} \mathcal{S}^\text{fin}_*, \mathcal{D}) \to \text{Exc}_*(\prod_{s \in S} \mathcal{S}^\text{fin}_*, \mathcal{D})$ be a left adjoint to the inclusion. Unwinding the definitions, we can identify $\nu$ with the canonical map $P_{\bar{1}}(Z) \circ U \to P_{\bar{1}}(Z \circ U)$, which is an equivalence by virtue of Remark 6.1.1.30. $\square$
Let \( F : \prod_{t \in T} \mathcal{C}_t \rightarrow \mathcal{D} \) be as in Proposition 6.2.1.18 and let \( q : S \rightarrow T \) be a surjection of finite sets. For \( \{X_t \in \text{Sp}(\mathcal{C}_t)\}_{t \in T} \), we have a canonical map

\[
F(\{\Omega^\infty X_t\}_{t \in T}) = F^+((\{X_t\}_{t \in T}),(S^0,S^0,\ldots,S^0) \rightarrow \Omega^\infty F^+((X_t))
\]

This construction determines a natural transformation \( \alpha : F \circ \prod_{t \in T} \Omega^\infty_{\mathcal{C}_t} \rightarrow \Omega^\infty_D \circ F^+ \).

**Proposition 6.2.1.19.** Let \( \{\mathcal{C}_t\}_{t \in T} \) be a nonempty finite collection of differentiable \( \infty \)-categories, let \( \mathcal{D} \) be a differentiable \( \infty \)-category, and let \( F : \prod_{t \in T} \mathcal{C}_t \rightarrow \mathcal{D} \) be a reduced functor which preserves sequential colimits. For every surjection of finite sets \( q : S \rightarrow T \), the natural transformation \( \alpha : F \circ \prod_{t \in T} \Omega^\infty_{\mathcal{C}_t} \rightarrow \Omega^\infty_D \circ F^+ \) defined above exhibits \( F^+ \) as a derivative of \( F \).

**Proof.** Let \( P_T : \text{Fun}_* (\prod_{t \in T} \text{Sp}(\mathcal{C}_t), \mathcal{D}) \rightarrow \text{Exc}_* (\prod_{t \in T} \text{Sp}(\mathcal{C}_t), \mathcal{D}) \) be a left adjoint to the inclusion. Since the functor \( F^+ \) is multilinear, the natural transformation \( \alpha \) factors as a composition

\[
F \circ \prod_{t \in T} \Omega^\infty_{\mathcal{C}_t} \xrightarrow{\alpha'} P_T (F \circ \prod_{t \in T} \Omega^\infty_{\mathcal{C}_t}) \xrightarrow{\alpha''} \Omega^\infty_D \circ F^+.
\]

To prove that \( \alpha \) exhibits \( F^+ \) as a derivative of \( F \), it will suffice to show that \( \alpha'' \) is an equivalence (Remark 6.2.1.8). Fix a collection of spectrum objects \( \{X_t \in \text{Sp}(\mathcal{C}_t)\}_{t \in T} \). For \( \bar{n} \in \mathbb{Z}^S_{\geq 0} \) and \( t \in T \), we let \( \bar{n}_t \) denote the restriction of \( \bar{n} \) to the subset \( S_t \subseteq S \). Note that the construction \( \bar{n} \mapsto \{\bar{n}_t\}_{t \in T} \) induces a cofinal map of partially ordered sets \( \mathbb{Z}^S_{\geq 0} \rightarrow \mathbb{Z}^{S_t}_{\geq 0} \). Using Remark 6.2.1.13, we compute

\[
(\Omega^\infty_D \circ F^+)((X_t)) = (\Omega^\infty_D \circ L_D^S)(F^+((X_t))) \\
\approx \lim_{\bar{n} \in \mathbb{Z}^S_{\geq 0}} (\Omega^\infty_D^{|\bar{n}|} F(\{X(S)|\bar{n}_t|\})) \\
\approx \lim_{\bar{n} \in \mathbb{Z}^S_{\geq 0}} (\Omega^\infty_D^{|\bar{n}|} F \circ \prod_{t \in T} \Omega^\infty_{\mathcal{C}_t}) \circ \prod_{t \in T} \Sigma^{|\bar{n}_t|}_{\text{Sp}(C_t)} (X_t) \\
\approx P_T(F \circ \Omega^\infty_{\mathcal{C}_t})(\{X_t\}).
\]

When using Proposition 6.2.1.19 to compute derivatives of functors, the following result is often useful:

**Proposition 6.2.1.20.** Let \( q : S \rightarrow T \) be a surjective map of nonempty finite sets, let \( \{\mathcal{C}_t\}_{t \in T} \) be a collection of differentiable \( \infty \)-categories, let \( \mathcal{D} \) be a differentiable \( \infty \)-category, and let \( F : \prod_{t \in T} \mathcal{C}_t \rightarrow \mathcal{D} \) be a reduced functor which preserves sequential colimits. For each \( t \in T \), let \( S_t = q^{-1}\{t\} \subseteq S \), and let

\[
F^+ : \prod_{t \in T} \text{Fun}_* (\prod_{s \in S_t} S^E_{s}, \mathcal{C}_t) \rightarrow \text{Fun}_* (\prod_{s \in S} S^E_{s}, \mathcal{D})
\]

denote the functor given by composition with \( F \). Then \( F^+ \) carries \( \prod_{t \in T} \text{L}_{S_t}^{S^E_t} \)-equivalences to \( \text{L}_{D^S}^{S^E_t} \)-equivalences.

**Proof.** Let \( P_T^t : \text{Fun}_* (\prod_{s \in S} S^E_{s}, \mathcal{D}) \rightarrow \text{Exc}_* (\prod_{s \in S} S^E_{s}, \mathcal{D}) \) be a left adjoint to the inclusion, and for each \( t \in T \) let \( P_T^t : \text{Fun}_* (\prod_{s \in S_t} S^E_{s}, \mathcal{C}_t) \rightarrow \text{Exc}_* (\prod_{s \in S} S^E_{s}, \mathcal{C}_t) \) be a left adjoint to the inclusion. Suppose we are given a collection of morphisms \( \{\alpha_t : X_t \rightarrow Y_t\}_{t \in T} \) in the \( \infty \)-categories \( \text{Fun}_* (\prod_{s \in S} S^E_{s}, \mathcal{C}_t) \) such that each \( P_T^t(\alpha_t) \) is an equivalence. We wish to show that the induced map \( P_T^t F^+((X_t)) \rightarrow P_T^t F^+((Y_t)) \) is an equivalence. Fix a finite collection of pointed spaces \( \{K_s \in S\} \). Using the description of \( P_T^t \) supplied by Example 6.1.1.28, we are reduced to proving that the canonical map

\[
\gamma : \lim_{\bar{n} \in \mathbb{Z}^S_{\geq 0}} \Omega^{|\bar{n}|}_{D} F(\{X_t((\Sigma^m K_s)_{s \in S_t})\}_{t \in T}) \rightarrow \lim_{\bar{n} \in \mathbb{Z}^S_{\geq 0}} \Omega^{|\bar{n}|}_{D} F(\{Y_t((\Sigma^m K_s)_{s \in S_t})\}_{t \in T})
\]
is an equivalence in $\mathcal{D}$. For $\vec{n} \in \mathbb{Z}_{\geq 0}^S$, let $\vec{n}_t$ denote the restriction of $\vec{n}$ to the subset $S_t \subseteq S$. We have a commutative diagram

$$
\begin{align*}
\lim_{\vec{m}, \vec{n} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle X_t(\{\Sigma^m K_s\}_{s \in S_t}) \rangle_{t \in T}) & \longrightarrow \lim_{\vec{m}, \vec{n} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle Y_t(\{\Sigma^m K_s\}_{s \in S_t}) \rangle_{t \in T}) \\
\lim_{\vec{m}, \vec{n} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle \Omega^{[\vec{n}_t]}_{\mathcal{C}_t} X_t(\{\Sigma^m+n K_s\}_{s \in S_t}) \rangle_{t \in T}) & \longrightarrow \lim_{\vec{m}, \vec{n} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle \Omega^{[\vec{n}_t]}_{\mathcal{C}_t} Y_t(\{\Sigma^m+n K_s\}_{s \in S_t}) \rangle_{t \in T}) \\
\lim_{\vec{m}, \vec{n} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle \Omega^{[\vec{n}_t]}_{\mathcal{C}_t} X_t(\{\Sigma^m+n K_s\}_{s \in S_t}) \rangle_{t \in T}) & \longrightarrow \lim_{\vec{m}, \vec{n} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle \Omega^{[\vec{n}_t]}_{\mathcal{C}_t} Y_t(\{\Sigma^m+n K_s\}_{s \in S_t}) \rangle_{t \in T}).
\end{align*}
$$

A simple cofinality argument shows that the vertical composite maps are equivalences, so that we can regard $\gamma$ as a retract of $\gamma'$ in the $\infty$-category $\text{Fun}(\Delta^1, \mathcal{D})$. It will therefore suffice to show that $\gamma'$ is an equivalence. Since the functors $\Omega_{\mathcal{D}}$ and $F$ commute with sequential colimits, it will suffice to show that each of the maps

$$
\lim_{\vec{m} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle X_t(\{\Sigma^m+n K_s\}_{s \in S_t}) \rangle_{t \in T}) \longrightarrow \lim_{\vec{m} \in \mathbb{Z}_{\geq 0}^S} \Omega_{\mathcal{D}}^{[|\vec{m}|]} F(\langle Y_t(\{\Sigma^m+n K_s\}_{s \in S_t}) \rangle_{t \in T}),
$$

which follows immediately from our assumption that $P^f_1(\alpha_t)$ is an equivalence. \hfill \square

We conclude this section by describing an application of Propositions 6.2.1.19 and 6.2.1.20.

**Notation 6.2.1.21.** Let $\{\mathcal{C}_s\}_{s \in S}$ and $\mathcal{D}$ be differentiable $\infty$-categories. We let $\text{Fun}_{\mathcal{D}}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})$ spanned by those functors which are reduced in each variable and preserve sequential colimits. If each $\mathcal{C}_s$ admits finite colimits, we let $\text{Exc}_{\mathcal{D}}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})$ spanned by those functors which are multilinear and preserve sequential colimits.

**Theorem 6.2.1.22 (Chain Rule for First Derivatives).** Suppose we are given a surjective map of nonempty finite sets $p : S \to T$, differentiable $\infty$-categories $\{\mathcal{C}_s\}_{s \in S}$, $\{\mathcal{D}_t\}_{t \in T}$, and $\mathcal{E}$, and functors functors $\{F_t \in \text{Fun}_{\mathcal{D}_t}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}_t)\}_{t \in T}$ and $g \in \text{Fun}_{\mathcal{D}_t}(\prod_{s \in S} \text{Sp}(\mathcal{E}), \text{Sp}(\mathcal{D}_t))$. Let $\{f_t \in \text{Exc}_{\mathcal{D}_t}(\prod_{s \in S} \text{Sp}(\mathcal{E}), \text{Sp}(\mathcal{D}_t))\}_{t \in T}$ and $g \in \text{Exc}_{\mathcal{D}_t}(\prod_{s \in S} \text{Sp}(\mathcal{E}), \text{Sp}(\mathcal{D}_t))$ be functors equipped with natural transformations

$$
F_t \circ \prod_{s \in S_t} \Omega_{\mathcal{C}_s}^{\infty} \longrightarrow \Omega_{\mathcal{C}_s}^{\infty} \circ f_t, \quad G \circ \prod_{t \in T} \Omega_{\mathcal{D}_t}^{\infty} \longrightarrow \Omega_{\mathcal{D}_t}^{\infty} \circ g
$$

which exhibit $g$ as a derivative of $G$ and each $f_t$ as a derivative of $F_t$. Then the composite transformation

$$
\gamma : G \circ \prod_{t \in T} \Omega_{\mathcal{D}_t}^{\infty} \longrightarrow \prod_{t \in T} \Omega_{\mathcal{D}_t}^{\infty} \circ f_t \longrightarrow \Omega_{\mathcal{D}_t}^{\infty} \circ g \circ \prod_{t \in T} f_t
$$

exhibits the functor $g \circ \prod_{t \in T} f_t : \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \to \text{Sp}(\mathcal{E})$ as a derivative of $G \circ \prod_{t \in T} F_t$.

**Remark 6.2.1.23.** We can state Theorem 6.2.1.22 more informally as follows: given composable multifunctors $F_t : \prod_{s \in S_t} \mathcal{C}_s \to \mathcal{D}_t$ and $G : \prod_{t \in T} \mathcal{D}_t \to \mathcal{E}$ which are reduced in each variable and preserve sequential colimits, we have a canonical equivalence

$$
\delta(G) \circ \prod_{t \in T} F_t \simeq \delta(G) \circ \prod_{t \in T} \delta F_t.
$$
Corollary 6.2.1.24 (Klein-Rognes). Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be differentiable $\infty$-categories, and let $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{E}$ be reduced functors which preserve sequential colimits. Let $\alpha : F \circ \Omega^\infty_{\mathcal{C}} \to \Omega^\infty_{\mathcal{D}} \circ f$ be a natural transformation which exhibits a functor $f : \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{D})$ as a derivative of $F$, and let $\beta : G \circ \Omega^\infty_{\mathcal{D}} \to \Omega^\infty_{\mathcal{E}} \circ g$ be a natural transformation which exhibits $g : \text{Sp}(\mathcal{D}) \to \text{Sp}(\mathcal{E})$ as a derivative of $G$. Then the composite map

$$\gamma : G \circ F \circ \Omega^\infty_{\mathcal{C}} \xrightarrow{\alpha} G \circ \Omega^\infty_{\mathcal{D}} \circ f \xrightarrow{\beta} \Omega^\infty_{\mathcal{E}} \circ g \circ f$$

exhibits $g \circ f$ as a derivative of $G \circ F$.

Remark 6.2.1.25. For a proof of Corollary 6.2.1.24 in the setting of classical homotopy theory, we refer the reader to [86].

Corollary 6.2.1.26. Let $\{\mathcal{C}_s\}_{s \in S}$ be a nonempty finite collection of differentiable $\infty$-categories, let $\mathcal{D}$ and $\mathcal{E}$ be differentiable $\infty$-categories, and suppose we are given functors $F \in \text{Fun}_*(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})$, $G \in \text{Fun}_*(\mathcal{D}, \mathcal{E})$.

Assume that $G$ is left exact, so that pointwise composition with $G$ induces a functor $g : \text{Sp}(\mathcal{D}) \to \text{Sp}(\mathcal{E})$. Let $\alpha : F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \to \Omega^\infty_{\mathcal{D}} \circ f$ be a natural transformation which exhibits $f$ as a derivative of $F$. Then the induced map

$$G \circ F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \circ \alpha \to G \circ \Omega^\infty_{\mathcal{D}} \circ f = \Omega^\infty_{\mathcal{E}} \circ g \circ f$$

exhibits $g \circ f$ as a derivative of $G \circ F$. In particular, we have a canonical equivalence

$$\partial(G \circ F) \simeq g \circ \partial(F).$$

Proof. Combine Theorem 6.2.1.22 with Example 6.2.1.4 (one can also deduce this result directly from the construction of the derivative supplied by the proof of Proposition 6.2.1.9).

Proof of Theorem 6.2.1.22. Let $F^+_t$ and $G^+$ be defined as in Construction 6.2.1.14. Using Proposition 6.2.1.19, we may assume that the functors $F_t$ and $G$ are given by the compositions

$$\prod_{s \in S_t} \text{Sp}(\mathcal{C}_s) \xrightarrow{i_t} \prod_{s \in S_t} \text{Fun}_*(\mathcal{S}^\text{fin}_{t_s}, \mathcal{C}_s) \xrightarrow{F^+_t} \text{Fun}_*(\prod_{s \in S_t} \mathcal{S}^\text{fin}_{t_s}, \mathcal{D}_t) \xrightarrow{L^S_{\mathcal{D}_t}} \text{Sp}(\mathcal{D}_t)$$

$$\prod_{t \in T} \text{Sp}(\mathcal{D}_t) \xrightarrow{j} \prod_{t \in T} \text{Fun}_*(\prod_{s \in S_t} \mathcal{S}^\text{fin}_{t_s}, \mathcal{D}_t) \xrightarrow{G^+} \text{Fun}_*(\prod_{s \in S_t} \mathcal{S}^\text{fin}_{t_s}, \mathcal{E}) \xrightarrow{L^S_{\mathcal{E}}} \text{Sp}(\mathcal{E}).$$

The natural transformation $\gamma$ can be written as a composition

$$G \circ \prod_{t \in T} F_t \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \xrightarrow{\gamma'} \Omega^\infty_{\mathcal{E}} \circ L^S_{\mathcal{E}} \circ G^+ \circ \prod_{t \in T} F^+_t \circ \prod_{t \in T} i_t$$

$$\xrightarrow{\gamma''} \Omega^\infty_{\mathcal{E}} \circ L^S_{\mathcal{E}} \circ G^+ \circ j \circ \prod_{t \in T} L^S_{\mathcal{D}_t} \circ \prod_{t \in T} F^+_t \circ \prod_{t \in T} i_t.$$

Proposition 6.2.1.19 implies that $\gamma'$ exhibits the functor $L^S_{\mathcal{E}} \circ G^+ \circ \prod_{t \in T} F^+_t \circ \prod_{t \in T} i_t$ as a derivative of $G \circ \prod_{t \in T} F_t$. To complete the proof, it will suffice to show that $\gamma''$ is an equivalence. Note that $\gamma''$ is induced by a natural transformation

$$\beta : L^S_{\mathcal{E}} \circ G^+ \to L^S_{\mathcal{E}} \circ G^+ \circ j \circ \prod_{t \in T} L^S_{\mathcal{D}_t}$$

of functors from $\prod_{t \in T} \text{Fun}(\prod_{s \in S_t} \mathcal{S}^\text{fin}_{t_s}, \mathcal{D}_t)$ to $\text{Sp}(\mathcal{E})$. Proposition 6.2.1.20 implies that $\beta$ is an equivalence. \qed
6.2. DIFFERENTIATION

6.2.2 Stabilization of Differentiable Fibrations

Let $\mathbf{Cat}_{\infty}^*$ denote the subcategory of $\mathbf{Cat}_{\infty}$ whose objects are differentiable $\infty$-categories and whose morphisms are reduced functors which preserve sequential colimits. Let $\mathbf{Cat}_{\infty}^{\text{Ex},*}$ denote the subcategory of $\mathbf{Cat}_{\infty}$ whose objects are stable $\infty$-categories which admit countable colimits and whose morphisms are functors which preserve countable colimits. We can define a functor

$$\Phi_0 : h\mathbf{Cat}_{\infty}^* \rightarrow h\mathbf{Cat}_{\infty}^{\text{Ex},*},$$

given on objects by $\mathcal{C} \mapsto \text{Sp}(\mathcal{C})$ and on morphisms by $F \mapsto \partial F$. It follows from Example 6.2.1.4 and Corollary 6.2.1.24 that this construction preserves identity morphisms and composition of morphisms, up to homotopy.

Our main goal in this section is to prove the following result:

**Theorem 6.2.2.1.** The functor $\Phi_0 : h\mathbf{Cat}_{\infty}^* \rightarrow h\mathbf{Cat}_{\infty}^{\text{Ex},*}$ lifts to a functor of $\infty$-categories $\Phi : \mathbf{Cat}_{\infty}^* \rightarrow \mathbf{Cat}_{\infty}^{\text{Ex},*}$.

Our basic strategy for proving Theorem 6.2.2.1 is to construct the coCartesian fibration $X \rightarrow \mathbf{Cat}_{\infty}^*$ classified by the composite map $\mathbf{Cat}_{\infty}^* \xrightarrow{\Phi} \mathbf{Cat}_{\infty}^{\text{Ex},*} \hookrightarrow \mathbf{Cat}_{\infty}$.

We can obtain $X$ by stabilizing the fibration $Y \rightarrow \mathbf{Cat}_{\infty}^*$ classified by the inclusion $\mathbf{Cat}_{\infty}^* \hookrightarrow \mathbf{Cat}_{\infty}$.

**Construction 6.2.2.2.** Let $p : \mathcal{C} \rightarrow S$ be an inner fibration of simplicial sets. For each $s \in S$, we let $\mathcal{C}_s$ denote the $\infty$-category $\mathcal{C} \times S\{s\}$. Assume that each of the $\infty$-categories $\mathcal{C}_s$ admits finite limits. We define simplicial sets $\text{Stab}(p) \subseteq \text{PStab}(p) \subseteq \text{PStab}(p) \rightarrow S$ as follows:

- For every map of simplicial sets $K \rightarrow S$, we have a canonical bijection
  $$\text{Hom}_S(K, \text{PStab}(p)) \simeq \text{Hom}_S(K \times S_{\text{fin}}^*, \mathcal{C}_s).$$

  In particular, we can identify vertices of $\text{PStab}(p)$ with pairs $(s, X)$, where $s$ is a vertex of $S$ and $X : S_{\text{fin}}^* \rightarrow \mathcal{C}_s$ is a functor.

- We let $\text{PStab}_*(p)$ denote the full simplicial subset of $\text{PStab}(p)$ spanned by those pairs $(s, X)$ for which $X$ is a reduced functor.

- We let $\text{Stab}(p)$ denote the full simplicial subset of $\text{PStab}(p)$ spanned by those pairs $(s, X)$ where $X$ is a spectrum object of $\mathcal{C}_s$.

**Remark 6.2.2.3.** Suppose we are given a pullback diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{C}' & \rightarrow & \mathcal{C} \\
\downarrow{p'} & & \downarrow{p} \\
S' & \rightarrow & S
\end{array}
$$

where the vertical maps are inner fibrations whose fibers admit finite limits. We then have canonical isomorphisms

$$\text{PStab}(p') \simeq S' \times_S \text{PStab}(p) \quad \text{PStab}_*(p) \simeq S' \times_S \text{PStab}_*(p) \quad \text{Stab}(p') \simeq S' \times_S \text{Stab}(p).$$

**Remark 6.2.2.4.** In the situation of Construction 6.2.2.2, we have a canonical isomorphism $\text{Stab}(p)_s \simeq \text{Sp}(\mathcal{C}_s)$ for each vertex $s \in S$. In other words, we can think of the construction $p \mapsto \text{Stab}(p)$ as a relative version of the construction $\mathcal{C} \mapsto \text{Sp}(\mathcal{C})$. 
Proposition 6.2.2.5. Let $p : \mathcal{C} \to S$ be an inner fibration of simplicial sets, where each fiber $\mathcal{C}_s$ admits finite limits. Then the maps
\[ \text{Stab}(p) \to \text{PStab}_s(p) \to \text{PStab}(p) \to S \]
are inner fibrations.

Proof. The map $\text{PStab}(p) \to S$ is a pullback of the map $\text{Fun}(S^\text{fin}_0, \mathcal{C}) \to \text{Fun}(S^\text{fin}_0, S)$, and therefore an inner fibration by Corollary T.2.3.2.5. The maps $\text{Stab}(p) \to \text{PStab}_s(p) \to \text{PStab}(p)$ are inclusions of full simplicial subsets, and therefore automatically inner fibrations.

Definition 6.2.2.6. Let $p : \mathcal{C} \to S$ be a map of simplicial sets. We will say that $p$ is a locally differentiable fibration if the following conditions are satisfied:

(a) The map $p$ is a locally coCartesian fibration of simplicial sets.

(b) For each fiber $s \in S$, the $\infty$-category $\mathcal{C}_s$ is differentiable.

(c) For each edge $s \to s'$ in $S$, the induced functor $\mathcal{C}_s \to \mathcal{C}_{s'}$ preserves sequential colimits.

We will say that a locally differentiable fibration is reduced if it satisfies the following further condition:

(d) For each edge $s \to s'$ in $S$, the induced functor $\mathcal{C}_s \to \mathcal{C}_{s'}$ is reduced.

We will say that a locally differentiable fibration $p$ is a differentiable fibration if it is locally differentiable and a coCartesian fibration.

Remark 6.2.2.7. Let $p : \mathcal{C} \to S$ be a coCartesian fibration of simplicial sets, classified by a map $\chi : S \to \text{Cat}_{\infty}$. Then $p$ is a reduced differentiable fibration if and only if $\chi$ factors through the subcategory $\text{Cat}_{\infty}^* \subseteq \text{Cat}_{\infty}$.

Proposition 6.2.2.8. Let $p : \mathcal{C} \to S$ be an inner fibration of simplicial sets, and assume that each fiber $\mathcal{C}_s$ of $p$ admits finite limits.

1. Assume that $p$ is a coCartesian fibration. Then the induced map $q : \text{PStab}(p) \to S$ is a coCartesian fibration. Moreover, an edge $e : (s, X) \to (s', X')$ in $\text{PStab}(p)$ is $q$-coCartesian if and only if, for every finite pointed space $K \in S^\text{fin}_*$, the resulting edge $e(K) : X(K) \to X'(K)$ is a $p$-coCartesian edge of $\mathcal{C}$.

2. Assume that $p$ is a coCartesian fibration and that, for each edge $s \to s'$ in $S$, the induced functor $\mathcal{C}_s \to \mathcal{C}_{s'}$ is reduced. Then the map $q' : \text{PStab}_s(p) \to S$ is a coCartesian fibration. Moreover, an edge $e$ of $\text{PStab}_s(p)$ is $q'$-coCartesian if and only if it is $q$-coCartesian, when regarded as an edge of $\text{PStab}(p)$.

3. If $p$ is a reduced locally differentiable fibration, then the induced map $q'' : \text{Stab}(p) \to S$ is a locally coCartesian fibration.

4. If $p$ is a reduced differentiable fibration, then $q'' : \text{Stab}(p) \to S$ is a coCartesian fibration.

Proof. Assertion (1) follows from Proposition T.3.1.2.1, and (2) follows immediately from (1). We now prove (3). Since $q''$ is an inner fibration by Proposition 6.2.2.5, we may reduce to the case where $S = \Delta^1$. Then the map $p : \mathcal{C} \to \Delta^1$ is a coCartesian fibration classifying a reduced functor $F : \mathcal{C}_0 \to \mathcal{C}_1$ which preserves sequential colimits. Let $X \in \text{Sp}(\mathcal{C}_0) \subseteq \text{Fun}(S^\text{fin}_0, \mathcal{C}_0)$; we wish to show that there exists a morphism $\alpha : F \circ X \to Y$ in $\text{Fun}_*(S^\text{fin}_0, \mathcal{C}_1)$, where $Y \in \text{Sp}(\mathcal{C}_1)$ and composition with $\alpha$ induces a homotopy equivalence $\text{Map}_{\text{Sp}(\mathcal{C}_1)}(Y, Z) \to \text{Map}_{\text{Fun}_*}(S^\text{fin}_0, \mathcal{C}_1)(F \circ X, Z)$. To prove the existence of $Y$, it suffices to note that the inclusion $\text{Fun}_*(S^\text{fin}_0, \mathcal{C}_1) \subseteq \text{Sp}(\mathcal{C}_1)$ admits a left adjoint (Corollary 6.2.1.12).
6.2. DIFFERENTIATION

We now prove (4). Assume that $p$ is a reduced differentiable fibration. Since $q'' : \text{Stab}(p) \to S$ is a locally coCartesian fibration by (3), it will suffice to show that the collection of locally $q''$-coCartesian edges is closed under composition (Proposition T.2.4.2.8). Suppose we are given a 2-simplex

![Diagram]

in $\text{Stab}(p)$, where $X \in \text{Sp}(C_x)$, $Y \in \text{Sp}(C_y)$, and $Z \in \text{Sp}(C_z)$, and the morphisms $\alpha$ and $\beta$ are locally $q''$-coCartesian. We wish to show that $\gamma$ is locally $q''$-coCartesian. The images of $\alpha$ and $\beta$ in $S$ determine functors $F : C_x \to C_y$ and $G : C_y \to C_z$. Let $L_y : \text{Fun}_s(S^{\text{fin}}_y, C_y) \to \text{Sp}(C_y)$ and $L_z : \text{Fun}_s(S^{\text{fin}}_z, C_z) \to \text{Sp}(C_z)$ denote left adjoints to the inclusion functors. Using the first part of the proof, we may assume without loss of generality that $Y = L_y(F \circ X)$ and $Z = L_z(G \circ Y)$. Then $\alpha$ and $\beta$ determine a natural transformation $\delta : G \circ F \circ X \to L_z(G \circ L_y(F \circ X))$. To prove that $\gamma$ is locally $q''$-coCartesian, it will suffice to show that $L_z(\delta)$ is an equivalence. Equivalently, we wish to show that composition with $G$ carries the map $F \circ Z \to L_y(F \circ X)$ to an $L_z$-equivalence, which follows from Proposition 6.2.1.20.

**Notation 6.2.2.9.** Let $p : C \to S$ be an inner fibration whose fibers $C_s$ admit finite limits. We let $\Omega^\infty_p : \text{Stab}(p) \to C$ denote the functor given by evaluation on the 0-sphere $S^0 \in S^{\text{fin}}$.

**Proposition 6.2.2.10.** Let $p : C \to S$ be a reduced locally differentiable fibration. Let $e : s \to s'$ be an edge of $S$, so that $e$ induces functors

$$F : C_s \to C_{s'}, \quad f : \text{Sp}(C_s) \simeq \text{Stab}(p)_s \to \text{Stab}(p)_{s'} \simeq \text{Sp}(C_{s'}).$$

Then the functor $\Omega^\infty_p : \text{Stab}(p) \to C$ induces a natural transformation

$$F \circ \Omega^\infty_p \to \Omega^\infty_p \circ f$$

which exhibits $f$ as a derivative of $F$.

**Proof.** Combine Proposition 6.2.1.19 with the proof of Proposition 6.2.2.8. \[ \square \]

**Corollary 6.2.2.11.** Let $p : C \to S$ be a reduced locally differentiable fibration. Then for each edge $s \to s'$ in $S$ the induced functor $\text{Stab}(p)_s \to \text{Stab}(p)_{s'}$ preserves countable colimits. In particular, it is an exact functor between stable $\infty$-categories.

**Proof.** Combine Propositions 6.2.2.10 and 6.2.1.18. \[ \square \]

**Proof of Theorem 6.2.2.1.** The inclusion functor $\text{Cat}^\ast_{\infty} \hookrightarrow \text{Cat}_{\infty}$ classifies a reduced differentiable fibration $p : Y \to \text{Cat}^\ast_{\infty}$ (Remark 6.2.2.7). Let $X = \text{Stab}(p)$. Then the projection map $q : X \to \text{Cat}^\ast_{\infty}$ is a coCartesian fibration (Proposition 6.2.2.8), classified by a functor $\Phi : \text{Cat}^\ast_{\infty} \to \text{Cat}_{\infty}$. Using Remark 6.2.2.4 and Proposition 6.2.2.10, we see that $\Phi$ is given on objects by $C \mapsto \text{Sp}(C)$ and on morphisms by $F \mapsto \Phi F$. It follows immediately that $\Phi$ factors through the subcategory $\text{Cat}^\ast_{\infty}^{\text{Ex}} \subseteq \text{Cat}_{\infty}$, and that $\Phi$ is a lift of the functor $\Phi_0 : \text{hCat}^\ast_{\infty} \to \text{hCat}^\ast_{\infty}^{\text{Ex}}$ described in the introduction to this section. \[ \square \]

**Remark 6.2.2.12.** Theorem 6.2.2.1 can be improved upon: if we take into account non-invertible natural transformations, we can regard $\text{Cat}^\ast_{\infty}$ and $\text{Cat}^\ast_{\infty}^{\text{Ex}}$ as $(\infty, 2)$-categories, and the functor $\Phi$ can be extended to a functor of $(\infty, 2)$-categories. This can be deduced formally from the fact that the construction $p \mapsto \text{Stab}(p)$ is defined on (reduced) locally differentiable fibrations, rather than merely on (reduced) differentiable fibrations.

Proposition 6.2.2.8 has a counterpart for Cartesian fibrations:

**Proposition 6.2.2.13.** Let $p : C \to S$ be a Cartesian fibration of simplicial sets, and assume that each fiber $C_s$ of $p$ admits finite limits.
(1) The induced map \( q : \text{PStab}(p) \to S \) is a coCartesian fibration. Moreover, an edge \( e : (s, X) \to (s', X') \) in \( \text{PStab}(p) \) is \( q \)-Cartesian if and only if, for every finite pointed space \( K \in S_{\text{fin}} \), the resulting edge \( e(K) : X(K) \to X'(K) \) is a \( p \)-coCartesian edge of \( \mathcal{C} \).

(2) Assume that, for each edge \( s \to s' \) in \( S \), the induced functor \( \mathcal{C}_{s'} \to \mathcal{C}_s \) is reduced. Then the map \( q' : \text{PStab}_s(p) \to S \) is a Cartesian fibration. Moreover, an edge \( e \) of \( \text{PStab}_s(p) \) is \( q' \)-Cartesian if and only if it is \( q \)-coCartesian, when regarded as an edge of \( \text{PStab}(p) \).

(3) Assume that, for each edge \( s \to s' \) in \( S \), the induced functor \( \mathcal{C}_{s'} \to \mathcal{C}_s \) is left exact. Then the map \( q'' : \text{Stab}(p) \to S \) is a Cartesian fibration. Moreover, an edge \( e \) of \( \text{Stab}(p) \) is \( q'' \)-Cartesian if and only if it is \( q \)-Cartesian, when regarded as an edge of \( \text{PStab}(p) \).

Proof. Assertion (1) follows from Proposition T.3.1.2.1, and assertions (2) and (3) follow immediately from (1). \( \square \)

Corollary 6.2.2.14. Let \( p : \mathcal{C} \to S \) be a locally Cartesian fibration of simplicial sets. Assume that each fiber \( \mathcal{C}_s \) of \( p \) admits finite limits and that each edge \( s \to s' \) in \( S \) induces a left exact functor \( \mathcal{C}_{s'} \to \mathcal{C}_s \). Then:

(1) The induced map \( q : \text{Stab}(\mathcal{C}) \to S \) is a locally Cartesian fibration.

(2) The forgetful functor \( \Omega^\infty_p : \text{Stab}(p) \to \mathcal{C} \) carries locally \( q \)-Cartesian morphisms to locally \( p \)-Cartesian morphisms.

(3) Let \( e : s \to s' \) be an edge of \( S \), so that \( e \) induces functors

\[
F : \mathcal{C}_{s'} \to \mathcal{C}_s \quad f : \text{Sp}(\mathcal{C}_{s'}) \simeq \text{Stab}(p)_{s'} \to \text{Stab}(p)_s \simeq \text{Sp}(\mathcal{C}_s).
\]

Then \( \Omega^\infty_p \) induces an equivalence

\[
F \circ \Omega^\infty_{\mathcal{C}_{s'}} \simeq \Omega^\infty_{\mathcal{C}_s} \circ f,
\]

which exhibits \( f \) as a derivative of \( F \).

Proof. Assertion (1) follows from Propositions 6.2.2.13 and 6.2.2.5, assertion (2) follows from Proposition 6.2.2.13, and assertion (3) follows from (2) and Example 6.2.1.4. \( \square \)

It follows from the above analysis that differentiation preserves adjunctions:

Proposition 6.2.2.15. Suppose we are given a pair of adjoint functors

\[
\mathcal{C} \xrightarrow{F} \mathcal{D} \xleftarrow{G} \mathcal{D},
\]

where \( \mathcal{C} \) and \( \mathcal{D} \) are differentiable \( \infty \)-categories. Assume that \( F \) is reduced. Then:

(1) The functor \( F \) preserves sequential colimits.

(2) The functor \( G \) preserves finite limits.

(3) The functors \( F \) and \( G \) admit derivatives \( \partial F, \partial G \).

(4) The functors \( \partial F \) and \( \partial G \) are adjoint to one another.

Proof. Assertions (1) and (2) follow from Proposition T.5.2.3.5, and assertion (3) follows from Example 6.2.1.4 and Proposition 6.2.1.9. To prove (4), we note that an adjunction between \( F \) and \( G \) determines a correspondence of \( \infty \)-categories \( p : \mathcal{M} \to \Delta^1 \), with \( \mathcal{C} \simeq \mathcal{M} \times \Delta^1 \{0\} \) and \( \mathcal{D} \simeq \mathcal{M} \times \Delta^1 \{1\} \). Then \( p \) is a reduced differentiable fibration, so that the induced map \( q : \text{Stab}(p) \to \Delta^1 \) is a coCartesian fibration associated to the functor \( \partial F : \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{D}) \) (Proposition 6.2.2.10). Since \( p \) is also a Cartesian fibration, using (2) and Corollary 6.2.2.14 we conclude that \( q \) associated to the functor \( \partial G : \text{Sp}(\mathcal{D}) \to \text{Sp}(\mathcal{C}) \). It follows that the correspondence \( \text{Stab}(p) \to \Delta^1 \) realizes an adjunction between the functors \( \partial F \) and \( \partial G \). \( \square \)
Corollary 6.2.2.16. Suppose given a pair of adjoint functors
\[
\mathcal{C} \xrightarrow{F} \mathcal{D} \xleftarrow{G} \mathcal{E}
\]
between differentiable ∞-categories. Assume that \(F\) is reduced, and let \(g : \text{Sp}(\mathcal{D}) \to \text{Sp}(\mathcal{C})\) be the functor given by pointwise application of \(G\). Then:

1. The functor \(g\) admits a left adjoint \(f : \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{D})\).
2. If the functor \(G\) preserves sequential colimits, then the composite functor \(g \circ f\) is equivalent to the derivative \(\partial(G \circ F)\).
3. If \(\mathcal{D}\) is monadic over \(\mathcal{C}\), then the adjunction \(\text{Sp}(\mathcal{C}) \xrightarrow{f} \text{Sp}(\mathcal{D}) \xleftarrow{g} \text{Sp}(\mathcal{E})\) exhibit \(\mathcal{D}\) as monadic over \(\text{Sp}(\mathcal{C})\).

Proof. The functor \(g\) is a derivative of \(G\) (Example 6.2.1.4), so that assertion (1) follows from Proposition 6.2.2.15. Assertion (2) follows from Corollary 6.2.1.24, and assertion (3) follows from (1) and Example 4.7.4.10.

The following consequence of Corollary 6.2.2.16 will play an important role in §7.3:

Corollary 6.2.2.17. Suppose given an adjunction \(\mathcal{C} \xrightarrow{F} \mathcal{D} \xleftarrow{G} \mathcal{E}\) between differentiable ∞-categories. Assume that \(\mathcal{F}\) is reduced, \(G\) preserves sequential colimits, and that \(G\) exhibits \(\mathcal{D}\) as monadic over \(\mathcal{C}\). If the unit map \(\text{id}_\mathcal{C} \to G \circ F\) induces an equivalence \(\partial\text{id}_\mathcal{C} \to \partial(G \circ F)\), then \(G\) induces an equivalence of ∞-categories \(\text{Sp}(\mathcal{D}) \to \text{Sp}(\mathcal{C})\).

We conclude this section by characterizing the construction \(p \mapsto \text{Stab}(p)\) by a universal property. As a first step, let us introduce a definition which summarizes the important properties of \(\text{Stab}(p)\):

Definition 6.2.2.18. Let \(p : \mathcal{C} \to \mathcal{S}\) be a reduced locally differentiable fibration of simplicial sets. We will say that a map of simplicial sets \(\mathcal{U} : \mathcal{C} \to \mathcal{C}\) exhibits \(\mathcal{C}\) as a stabilization of \(p\) if the following conditions are satisfied:

1. The composite map \(q = p \circ \mathcal{U} : \mathcal{C} \to \mathcal{S}\) is a locally coCartesian fibration.
2. For each vertex \(s \in \mathcal{S}\), the ∞-category \(\mathcal{C}_s\) is stable.
3. For each vertex \(s \in \mathcal{S}\), the functor \(\mathcal{U}_s : \mathcal{C}_s \to \mathcal{C}_s\) is left exact. Consequently, \(\mathcal{U}_s\) admits an essentially unique factorization \(\mathcal{C}_s \xrightarrow{\mathcal{V}_s} \text{Sp}(\mathcal{C}_s) \xrightarrow{\Omega^\infty_{\mathcal{C}_s}} \mathcal{C}_s\), where \(\mathcal{V}_s\) is an exact functor (Corollary 1.4.2.23).
4. For each vertex \(s \in \mathcal{S}\), the functor \(\mathcal{V}_s : \mathcal{C}_s \to \text{Sp}(\mathcal{C}_s)\) is an equivalence of ∞-categories, and therefore admits a homotopy inverse which we will denote by \(\mathcal{V}_s^{-1}\).
5. Let \(e : s \to s'\) be an edge of \(\mathcal{S}\), so that \(e\) induces functors
\[
F : \mathcal{C}_s \to \mathcal{C}_{s'} \quad \mathcal{F} : \mathcal{C}_s \to \mathcal{C}_{s'}.
\]

Then the natural transformation
\[
F \circ \Omega^\infty_{\mathcal{C}_s} \simeq F \circ \mathcal{U}_s \circ \mathcal{V}_s^{-1} \to U_{s'} \circ \mathcal{F} \circ \mathcal{V}_s^{-1} \simeq \Omega^\infty_{\mathcal{C}_{s'}} \circ (\mathcal{V}_s \circ \mathcal{F} \circ \mathcal{V}_s^{-1})
\]
exhibits \(\mathcal{V}_{s'} \circ \mathcal{F} \circ \mathcal{V}_s^{-1}\) as a derivative of \(F\).

Example 6.2.2.19. Let \(p : \mathcal{C} \to \mathcal{S}\) be a reduced locally differentiable fibration of simplicial sets. Then the map \(\Omega^\infty_p : \text{Stab}(p) \to \mathcal{C}\) of Notation 6.2.2.9 exhibits \(\text{Stab}(p)\) as a stabilization of \(p\).
Stabilizations of a reduced locally differentiable fibration enjoy the following universal property:

**Theorem 6.2.2.20.** Let \( p : \mathcal{C} \rightarrow S \) be a reduced locally differentiable fibration of simplicial sets and let \( U : \overline{\mathcal{C}} \rightarrow \mathcal{C} \) be a map which exhibits \( \overline{\mathcal{C}} \) as a stabilization of \( p \). Let \( q : \mathcal{D} \rightarrow S \) be a locally coCartesian fibration of simplicial sets. Suppose that each fiber \( \mathcal{D}_s \) of \( q \) is a pointed \( \infty \)-category which admits finite colimits and each edge \( s \rightarrow s' \) of \( S \) induces a functor \( \mathcal{D}_s \rightarrow \mathcal{D}_{s'} \) which is reduced and right exact. Let \( \mathcal{X} \) denote the full subcategory of \( \text{Fun}_S(\mathcal{D}, \mathcal{C}) \) spanned by those maps \( F : \mathcal{D} \rightarrow \mathcal{C} \) which induce a reduced excisive functor \( F_s : \mathcal{D}_s \rightarrow \mathcal{C}_s \) for each \( s \in S \), and define \( \overline{\mathcal{X}} \subseteq \text{Fun}_S(\mathcal{D}, \overline{\mathcal{C}}) \) similarly. Then composition with \( U \) induces an equivalence of \( \infty \)-categories \( \overline{\mathcal{X}} \rightarrow \mathcal{X} \).

**Remark 6.2.2.21.** For most applications of Theorem 6.2.2.20, we will take \( q \) to be a locally coCartesian fibration whose fibers are stable \( \infty \)-categories.

**Remark 6.2.2.22.** We can regard Theorem 6.2.2.20 as a relative version of Proposition 1.4.2.22.

**Corollary 6.2.2.23.** Let \( p : \mathcal{C} \rightarrow S \) be a reduced locally differentiable fibration, and let \( U : \overline{\mathcal{C}} \rightarrow \mathcal{C} \) be a map which exhibits \( \overline{\mathcal{C}} \) as a stabilization of \( p \). Then \( U \) factors as a composition

\[
\overline{\mathcal{C}} \xrightarrow{U'} \text{Stab}(p) \xrightarrow{\Omega^\infty_p} \mathcal{C},
\]

where \( U' \) is an equivalence of local coCartesian fibrations over \( S \) (that is, \( U' \) induces an equivalence of \( \infty \)-categories \( \overline{\mathcal{C}}_s \rightarrow \text{Stab}(p)_s \simeq \text{Sp}(\mathcal{C}_s) \) for each \( s \in S \), and carries locally \((p \circ U)\)-coCartesian edges of \( \overline{\mathcal{C}} \) to locally \((p \circ \Omega^\infty_p)\)-coCartesian edges of \( \text{Stab}(p) \).

**Remark 6.2.2.24.** The conclusions of Corollary 6.2.2.23 guarantee that \( U' \) admits a homotopy inverse fiberwise over \( S \); see Lemma B.2.4. In other words, \( \text{Stab}(p) \) is the unique stabilization of the reduced locally differentiable fibration \( p : \mathcal{C} \rightarrow S \), up to fiberwise homotopy equivalence over \( S \).

**Proof of Corollary 6.2.2.23.** Since \( U \) exhibits \( \overline{\mathcal{C}} \) as a stabilization of \( p \), each fiber \( \overline{\mathcal{C}}_s \) is equivalent to \( \text{Stab}(\mathcal{C}_s) \) and is therefore a stable \( \infty \)-category which admits countable colimits. Moreover, every edge \( s \rightarrow s' \) induces a functor \( \overline{\mathcal{C}}_s \rightarrow \overline{\mathcal{C}}_{s'} \) which is equivalent to the derivative of the underlying functor \( \mathcal{C}_s \rightarrow \mathcal{C}_{s'} \), and therefore preserves countable colimits (Proposition 6.2.1.18). Note that composition with \( \Omega^\infty_p \) induces a categorical fibration of \( \infty \)-categories \( \text{Fun}_S(\overline{\mathcal{C}}, \text{Stab}(p)) \rightarrow \text{Fun}_S(\overline{\mathcal{C}}, \mathcal{C}) \). Since \( \Omega^\infty \) exhibits \( \text{Stab}(p) \) as a stabilization of \( p \) (Example 6.2.19), Theorem 6.2.2.20 implies that \( U \) factors as a composition \( \Omega^\infty_p \circ U'' \), where \( U'' : \overline{\mathcal{C}} \rightarrow \text{Stab}(p) \) is a map which induces a left exact functor \( U'_s : \overline{\mathcal{C}}_s \rightarrow \text{Stab}(p)_s \simeq \text{Sp}(\mathcal{C}_s) \) for each vertex \( s \in S \). Since \( \overline{\mathcal{C}} \) satisfies condition (4) of Definition 6.2.2.18, we deduce that each of the functors \( U'_s \) is an equivalence of \( \infty \)-categories. Condition (5) of Definition 6.2.2.18 guarantees that \( U' \) carries locally \((p \circ U)\)-coCartesian edges to locally \((p \circ \Omega^\infty_p)\)-coCartesian edges.

Our proof of Theorem 6.2.2.20 will require an analogue of Proposition T.3.2.2.7, which describes the structure of locally coCartesian fibrations over a simplex. To state this result, we need to introduce a bit of notation.

**Notation 6.2.2.25.** Fix an integer \( n \geq 0 \). We can identify objects of the simplicial category \( \mathcal{C}[\Delta^{n+1}] \) with elements of the linearly ordered set \( [n+1] = \{0, \ldots, n+1\} \). For \( 0 \leq i \leq n \), we can identify vertices of \( \text{Map}_{\mathcal{C}[\Delta^{n+1}]}(i, n+1) \) with subsets \( S \subseteq \{i, i+1, \ldots, n\} \) which contain \( i \). The construction which assigns to each subset \( S \) its largest element extends uniquely to a map of simplicial sets \( \phi_i : \text{Map}_{\mathcal{C}[\Delta^{n+1}]}(i, n+1) \rightarrow \Delta^n \).

Let \( j_i : (\text{Set}_\Delta)^{\mathcal{C}[\Delta^n]} \rightarrow (\text{Set}_\Delta)^{\mathcal{C}[\Delta^{n+1}]} \) denote the functor given by left Kan extension along the inclusion \( j : \mathcal{C}[\Delta^n] \rightarrow \mathcal{C}[\Delta^{n+1}] \), and let \( M : (\text{Set}_\Delta)^{\mathcal{C}[\Delta^n]} \rightarrow \text{Set}_\Delta \) denote the composition of \( i \) with the functor \( (\text{Set}_\Delta)^{\mathcal{C}[\Delta^{n+1}]} \rightarrow \text{Set}_\Delta \) given by evaluation at \( n \). For every \( \mathcal{T} \in (\text{Set}_\Delta)^{\mathcal{C}} \), we can identify \( M(\mathcal{T}) \) with a quotient of the disjoint union \( \bigsqcup_{0 \leq i \leq n} \mathcal{T}(i) \times \text{Map}_{\mathcal{C}[\Delta^{n+1}]}(i, n+1) \). The maps \( \{\phi_i\}_{0 \leq i \leq n} \) determine a map of simplicial sets \( M(\mathcal{T}) \rightarrow \Delta^n \). This map depends functorially on \( \mathcal{T} \); we may therefore view \( M \) as defining a functor from \((\text{Set}_\Delta)^{\mathcal{C}[\Delta^n]} \) to \((\text{Set}_\Delta)/\Delta^n \). We will abuse notation by denoting this functor also by \( M \).
Remark 6.2.2.26. For every object \( \mathcal{F} \in (\text{Set}_\Delta)^{\Delta^n} \) and every \( 0 \leq i \leq n \), there is a canonical isomorphism \( M(\mathcal{F}) \times_{\Delta^n} \{ i \} \simeq \mathcal{F}(i) \). Moreover, the marking on this simplicial set provided by \( M(\mathcal{F})^+ \) is trivial: only degenerate edges of \( \mathcal{F}(i) \) are marked.

Proposition 6.2.2.27. Let \( \mathcal{F} \in \text{Set}_\Delta^{\Delta^n} \), and suppose we are given a commutative diagram

\[
\begin{array}{ccc}
M(\mathcal{F}) & \xrightarrow{f} & \mathcal{E} \\
\downarrow q & & \downarrow \alpha \downarrow \Delta^n \\
\Delta^n & & \\
\end{array}
\]

with the following properties:

1. The map \( q \) is a locally coCartesian fibration.
2. Let \( v \) be a vertex of \( \mathcal{F}(i) \), and let \( S \subseteq S' \subseteq \{ i, \ldots, n \} \) be subsets containing \( i \), so that there is an edge \( e \) joining the vertex \((v, S)\) to the vertex \((v, S')\) in the simplicial set \( \mathcal{F}(i) \times \text{Map}_{\Delta^{n+1}}(i, n+1) \). If \( S' - S \) consists of a single element, then the image of \( e \) under the map

\[
\mathcal{F}(i) \times \text{Map}_{\Delta^{n+1}}(i, n+1) \rightarrow M(\mathcal{F}) \xrightarrow{q} \mathcal{E}
\]

is a \( q \)-coCartesian morphism in \( \mathcal{E} \).
3. For \( 0 \leq i \leq n \), the composite map

\[
\mathcal{F}(i) \rightarrow M(\mathcal{F}) \times_{\Delta^n} \{ i \} \rightarrow \mathcal{E} \times_{\Delta^n} \{ i \}
\]

is a categorical equivalence.

Then \( f \) is a categorical equivalence.

Proof. The proof proceeds by induction on \( n \). If \( n = 0 \) the result is obvious, so we may suppose \( n > 0 \). Let \( \mathcal{F}_0 = \mathcal{F} \mid \mathcal{E}[\Delta^{n-1}] \). Unwinding the definition, we have a canonical isomorphism of simplicial sets

\[
\alpha : M(\mathcal{F}) \simeq (M(\mathcal{F}) \times \Delta^1) \coprod_{M(\mathcal{F}_0) \times \{ 1 \}} \mathcal{F}(n)
\]

Let \( q \) denote the composition \( \mathcal{E} \rightarrow \Delta^n \xrightarrow{q_0} \Delta^1 \), where \( q_0^{-1}(0) = \Delta^{n-1} \subseteq \Delta^n \). The map \( q \) is a coCartesian fibration of simplicial sets. The desired result now follows by combining the inductive hypothesis with Proposition T.3.2.2.10.

Proposition 6.2.2.28. Let \( \mathcal{E} \rightarrow \Delta^n \) be a locally coCartesian fibration of \( \infty \)-categories. Then there exists a projectively cofibrant diagram \( \mathcal{F} \in (\text{Set}_\Delta)^{\Delta^n} \) and a map \( f : M(\mathcal{F}) \rightarrow \mathcal{E} \) which satisfies the hypotheses of Proposition 6.2.2.27.

Proof. The proof goes by induction on \( n \). The result is obvious if \( n = 0 \), so assume \( n > 0 \). Let \( \mathcal{E}_0 = \mathcal{E} \times_{\Delta^n} \Delta^{n-1} \). The inductive hypothesis guarantees the existence of a projectively cofibrant diagram \( \mathcal{F}_0 \in (\text{Set}_\Delta)^{\Delta^{n-1}} \) and a map \( f_0 : M(\mathcal{F}_0) \rightarrow \mathcal{E}_0 \) satisfying the hypotheses of Proposition 6.2.2.27. Let \( q : \mathcal{E} \rightarrow \Delta^1 \) be defined as in the proof of Proposition 6.2.2.27. Then \( q \) is a coCartesian fibration, and \( f_0 \) determines a map of simplicial sets \( h_0 : M(\mathcal{F}_0) \times \{ 0 \} \rightarrow \mathcal{E} \times_{\Delta^1} \{ 0 \} \). We can therefore choose a \( q \)-coCartesian extension of \( h_0 \) to a map \( h : M(\mathcal{F}_0) \times \Delta^1 \rightarrow \mathcal{E} \), where \( h \mid M(\mathcal{F}_0) \times \{ 1 \} \) determines a map \( h_1 : M(\mathcal{F}_0) \rightarrow \mathcal{E} \times_{\Delta^n} \{ n \} \). Choose a factorization of \( h_1 \) as a composition

\[
M(\mathcal{F}_0) \xrightarrow{\delta'} X \xrightarrow{\delta''} \mathcal{E} \times_{\Delta^n} \{ n \},
\]

where \( \delta' \) is a cofibration of simplicial sets and \( \delta'' \) is a categorical equivalence. The map \( \delta' \) determines an extension of \( \mathcal{F}_0 \) to a functor \( \mathcal{F} \in (\text{Set}_\Delta)^{\Delta^n} \) with \( \mathcal{F}(n) = X \), and the maps \( h \) and \( \delta'' \) can be amalgamated to a map of marked simplicial sets \( M(\mathcal{F}) \rightarrow \mathcal{E} \) with the desired properties.
Lemma 6.2.2.29. Suppose given a commutative diagram of simplicial sets

\[ \begin{array}{ccc}
\mathcal{C} & \xrightarrow{U} & \mathcal{C} \\
\downarrow{p} \quad \uparrow{\Delta^n} & & \quad \downarrow{\Delta^n} \\
\mathcal{C} & & \mathcal{C}
\end{array} \]

where \( p \) is a reduced locally differentiable fibration and \( U \) exhibits \( \mathcal{C} \) as a stabilization of \( p \). Let \( \mathcal{D} \) be a pointed \( \mathcal{\infty} \)-category which admits finite colimits and a final object, let \( V \subseteq \text{Fun}(\mathcal{D}, \mathcal{C}) \) denote the full subcategory spanned by those functors given by reduced, excisive maps \( \mathcal{D} \to \mathcal{C}_i \) for some \( 0 \leq i \leq n \), and define \( \overline{V} \subseteq \text{Fun}(\mathcal{D}, \overline{\mathcal{C}}) \) similarly. Then composition with \( U \) induces a categorical equivalence \( \overline{V} \to V \).

Proof. Compositon with the map \( p \) and evaluation at a final object of \( \mathcal{D} \) determines a functor \( q : V \to \Delta^n \). Let \( \overline{q} = q \circ U \). Using Lemma B.2.4, we are reduced to proving the following:

(i) The projection \( \overline{q} : \mathcal{V} \to S \) is a locally \( q \)-coCartesian fibration.

(ii) The projection \( q : V \to S \) is a locally \( q \)-coCartesian fibration.

(iii) The map \( \overline{V} \to V \) carries locally \( \overline{q} \)-coCartesian edges to \( q \)-coCartesian edges.

(iv) For every vertex \( s \in S \), the induced map \( \mathcal{V}_s \to V_s \) is an equivalence of \( \mathcal{\infty} \)-categories.

The map \( q \) admits a factorization

\[ V \to \text{Fun}(\mathcal{D}, \mathcal{C}) \times_{\text{Fun}(\mathcal{D}, \Delta^n)} \Delta^n \to \Delta^n. \]

The first map is the inclusion of a full subcategory, and therefore an inner fibration. The second map is a pullback of the projection \( \text{Fun}(\mathcal{D}, \mathcal{C}) \to \text{Fun}(\mathcal{D}, \Delta^n) \), and therefore an inner fibration by Corollary T.2.3.2.5. It follows that \( q \) is an inner fibration; likewise \( \overline{q} \) is an inner fibration. To prove the remaining assertions, it suffices to treat the case \( n = 1 \). In particular, we may assume that \( p \) and \( \overline{q} \) are \( q \)-coCartesian fibrations.

We now prove (i). Proposition T.3.1.2.1 implies that the projection \( \overline{q} : \text{Fun}(\mathcal{D}, \overline{\mathcal{C}}) \to \text{Fun}(\mathcal{D}, \Delta^1) \) is a \( \overline{q} \)-coCartesian fibration. Moreover, an edge \( f \to g \) in the fiber product \( \text{Fun}(\mathcal{D}, \overline{\mathcal{C}}) \) is \( \overline{q} \)-coCartesian if and only if, for each \( D \in \mathcal{D} \), the induced edge \( f(D) \to g(D) \) is an \( \overline{p} \)-coCartesian edge of \( \overline{\mathcal{C}} \). Since every edge \( s \to s' \) induces an exact functor \( \overline{\mathcal{C}}_s \to \overline{\mathcal{C}}_{s'} \), we conclude that if \( f \in \mathcal{W} \), then \( g \in \mathcal{W} \). This proves that \( \overline{q} = \overline{q}|_{\mathcal{W}} \) is a \( \overline{q} \)-coCartesian fibration, and that an edge of \( \overline{\mathcal{W}} \) is \( \overline{q} \)-coCartesian if and only if it is \( \overline{q} \)-coCartesian.

Assertion (iv) follows immediately from Proposition 1.4.2.22. To prove (iii), write \( \mathcal{C} \) as the correspondence associated to a reduced functor \( \overline{F} : \mathcal{C}_0 \to \mathcal{C}_1 \) which preserves sequential colimits. Since \( U \) exhibits \( \mathcal{C} \) as a stabilization of \( p \), we can identify \( \overline{\mathcal{C}} \) with the correspondence associated to the derivative \( \partial F : \text{Sp}(\mathcal{C}_0) \to \text{Sp}(\mathcal{C}_1) \) of \( F \). Let \( G : \mathcal{D} \to \text{Sp}(\mathcal{C}_0) \) be a reduced, excisive functor and let \( e : G \to \partial F \circ G \) be the corresponding \( \overline{q} \)-coCartesian edge of \( \overline{\mathcal{C}} \); we wish to show that the image of \( e \) in \( V \) is \( q \)-coCartesian. Unwinding the definitions, we are reduced to proving that the canonical natural transformation \( F \circ \Omega^\infty_{\mathcal{C}_0} \circ G \to \Omega^\infty_{\mathcal{C}_1} \circ \partial F \circ G \) induces an equivalence \( P_!(F \circ \Omega^\infty_{\mathcal{C}_0} \circ G) \simeq \Omega^\infty_{\mathcal{C}_1} \circ \partial F \circ G \). This follows from Remark 6.1.1.30.

We now prove (ii). Suppose we are given an vertex \( f : \mathcal{D} \to \mathcal{C}_0 \) of \( V \); we wish to show that there exists a \( q \)-coCartesian morphism \( \alpha : f \to g \) in \( V \), for some \( g : \mathcal{D} \to \mathcal{C}_1 \). Using (iv), we may assume without loss of generality that \( f \) can be lifted to a vertex \( \overline{f} : \mathcal{D} \to \overline{\mathcal{C}}_0 \) in \( \overline{V} \). Using (i), we can choose an \( \overline{q} \)-coCartesian edge \( \overline{f} \to \overline{g} \) for some \( g : \mathcal{D} \to \overline{\mathcal{C}}_1 \). We now take \( \alpha \) to be the image of \( \overline{\alpha} \) in \( V \), which is \( q \)-coCartesian by virtue of (iii).

\[ \square \]

Proof of Theorem 6.2.2.20. According to Theorem B.0.20, there exists a model structure on the category of marked simplicial sets over \( S \) whose cofibrations are monomorphisms and whose fibrant objects are pairs \((X, E)\), where \( X \to S \) is a locally coCartesian fibration and \( E \) is the collection of locally coCartesian edges of \( X \). Without loss of generality, we may assume that the map \( U : \overline{\mathcal{C}} \to \mathcal{C} \) determines a fibration with respect to this model structure. We define a simplicial set \( Z \) by the following universal property: for every simplicial
set $K$, $\text{Hom}_{\text{Set}_\Delta}(K, Z)$ can be identified with the set of pairs $(b, \phi)$, where $b : K \to S$ is a map of simplicial sets and $\phi : K \times_S D \to K \times_S \mathcal{C}$ is a map which is compatible with the projection to $K$, and induces a reduced, excisive functor $D_{b(k)} \to C_{b(k)}$ for each vertex $k$ of $K$. Let $\mathcal{Z}$ be defined similarly, using $\mathcal{C}$ in place of $\mathcal{C}$. The map $\mathcal{X} \to \mathcal{X}$ is a pullback of the canonical map $\text{Fun}(S, \mathcal{Z}) \to \text{Fun}(S, Z)$. It will therefore suffice to show that the map $\mathcal{Z} \to \mathcal{Z}$ is a trivial Kan fibration. In other words, we need only show that every lifting problem of the form

$$
\begin{array}{ccc}
\partial \Delta^n & \to & \mathcal{Z} \\
\downarrow & & \downarrow \\
\Delta^n & \to & \mathcal{Z}
\end{array}
$$

admits a solution. Without loss of generality, we may replace $S$ by $\Delta^n$. Let $\mathcal{D}' = \mathcal{D} \times_{\Delta^n} \partial \Delta^n$. Unwinding the definitions, we are required to solve a lifting problem of the form

$$
\begin{array}{ccc}
\mathcal{D}' & \to & \mathcal{C} \\
\phi \downarrow & \nearrow & \downarrow \phi_0 \\
\mathcal{D} & \to & \mathcal{C}.
\end{array}
$$

Moreover, if $n = 0$, we must further guarantee that the functor $\phi$ is left exact.

Let us first consider the case $n = 0$. By assumption, the map $U$ is equivalent to the functor $\Omega_\infty^C : \text{Sp}(\mathcal{C}) \to \mathcal{C}$, and $\phi_0$ is a left exact functor whose domain is stable. Invoking Proposition 1.4.2.22, we deduce that $\phi_0 \simeq U \circ \phi'$, where $\phi' : \mathcal{D} \to \mathcal{C}$ is an exact functor. Since $U$ is a fibration, any equivalence of $U \circ \phi'$ with $\phi_0$ can be lifted to an equivalence of $\phi'$ with an exact functor $\phi : \mathcal{D} \to \mathcal{C}$ satisfying $U \circ \phi = \phi_0$.

We now treat the case $n > 0$. Since $q$ is a locally coCartesian fibration, Proposition 6.2.2.28 guarantees the existence of a simplicial functor $\mathcal{F} : \mathcal{C}[\Delta^n] \to \text{Set}_\Delta$ and a map $u : \mathcal{M}(\mathcal{F}) \to \mathcal{D}$ which induces categorical equivalences $\mathcal{F}(i) \to \mathcal{D} \times_{\Delta^n} \{i\}$ for $0 \leq i \leq n$. For every face $\sigma \subseteq \Delta^n$, let $W_{\sigma} = \mathcal{M}(\mathcal{F} | \mathcal{C} | \sigma)$. Finally, for every simplicial subset $S' \subseteq S$, let $W_{S'}$ denote the colimit $\text{colim}_{\sigma \in S'} W_{\sigma}$. For each $S' \subseteq S$, we have a canonical map $\psi_{S'} : W_{S'} \to Y \times_S S'$. Using Proposition 6.2.2.27, we deduce that $\psi_{S'}$ is a categorical equivalence whenever $S'$ is a simplex. Since the domain and codomain of $\psi_{S'}$ both carry pushout squares of simplicial subsets of $S$ to homotopy pushout squares of simplicial sets, we deduce that $\psi_{S'}$ is a categorical equivalence for all $S' \subseteq S$. Invoking Proposition T.A.2.3.1, we are reduced to solving the lifting problem depicted in the diagram

$$
\begin{array}{ccc}
W_{\partial \Delta^n} & \to & \mathcal{C} \\
\downarrow & & \downarrow U \\
W_{\Delta^n} & \to & \mathcal{C}.
\end{array}
$$

Let $C = (\Delta^1)^n$ denote an $n$-dimensional cube, and $\partial C$ its boundary. Then the left vertical map is a pushout of the inclusion $\langle \partial C \rangle \times \mathcal{F}(0) \subseteq C \times \mathcal{F}(0)$. Consequently, the above lifting problem is equivalent to providing a dotted arrow in the diagram

$$
\begin{array}{ccc}
(\partial C) \times \mathcal{F}(0) & \to & \mathcal{C} \\
\downarrow & & \downarrow U \\
C \times \mathcal{F}(0) & \to & \mathcal{C}.
\end{array}
$$

We may assume without loss of generality that the functor $\mathcal{F}$ is projectively fibrant (otherwise, we simply make a fibrant replacement for $\mathcal{F}$), so that $\mathcal{F}(0)$ is an $\infty$-category which is equivalent to the fiber $\mathcal{D} \times_{\Delta^n} \{0\}$. In particular, $\mathcal{F}(0)$ admits finite colimits and a final object. Let $V$ denote the full simplicial subset of $\text{Fun}(\mathcal{F}(0), \mathcal{C})$ spanned by those functors which belong to $\text{Exc}_{s}(\mathcal{F}(0), \mathcal{C})$ for some $0 \leq i \leq n$, and define $V$
similarly. We can now rewrite our lifting problem yet again:

\[
\begin{array}{ccc}
\partial C & \to & V \\
\downarrow & & \downarrow \\
C & \to & U'.
\end{array}
\]

To solve this lifting problem, it suffices to show that \(U'\) is a trivial Kan fibration. Our assumption on \(U\) guarantees that \(U'\) is a categorical fibration. We complete the proof by observing that Lemma 6.2.2.29 guarantees that \(U'\) is a categorical equivalence. 

\[\square\]

### 6.2.3 Differentials of Functors

Let \(F : \mathcal{C} \to \mathcal{D}\) be a functor between \(\infty\)-categories which admit finite limits. In §6.2.1, we defined the derivative \(\partial F\) of \(F\), as a functor from \(\text{Sp}(\mathcal{C})\) to \(\text{Sp}(\mathcal{D})\). In this section, we introduce a closely related notion, which we call the differential of \(F\).

**Definition 6.2.3.1.** Let \(\{\mathcal{C}_s\}_{s \in S}\) be a finite collection of \(\infty\)-categories which admit finite colimits and final objects, let \(\mathcal{D}\) be an \(\infty\)-category which admits finite limits, and suppose we are given functors \(F, F' : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}\). We will say that a natural transformation \(\beta : F \to F'\) exhibits \(F'\) as a differential of \(F\) if the following conditions are satisfied:

1. The functor \(F'\) is multilinear (that is, it is reduced and excisive in each variable).
2. For every multilinear functor \(G : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}\), composition with \(\beta\) induces a homotopy equivalence

\[
\text{Map}_{\text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})}(F', G) \to \text{Map}_{\text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})}(F, G).
\]

**Remark 6.2.3.2.** In the situation of Definition 6.2.3.1, if \(F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}\) admits a differential \(F'\), then the \(F'\) is determined by \(F\) up to canonical equivalence. We will sometimes indicate the dependence of \(F'\) on \(F\) by writing \(F' = DF\) or \(F' = D(F)\).

**Example 6.2.3.3.** In the situation of Definition 6.2.3.1, suppose that \(S\) is empty. Then every functor \(F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}\) is multilinear, so that a natural transformation \(\beta : F \to F'\) exhibits \(F'\) as a differential of \(F\) if and only \(\beta\) is an equivalence.

**Remark 6.2.3.4.** Let \(\{\mathcal{C}_s\}_{s \in S}\) and \(\mathcal{D}\) as in Definition 6.2.3.1, and suppose we are given functors

\[
F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D} \quad f : \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \to \text{Sp}(\mathcal{D}).
\]

If \(S\) is nonempty, then a natural transformation \(\alpha : F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s} \to \Omega^\infty_{\mathcal{D}} \circ f\) exhibits \(f\) as a derivative of \(F\) if and only if it exhibits \(\Omega^\infty_{\mathcal{D}} \circ f\) as a differential of \(F \circ \prod_{s \in S} \Omega^\infty_{\mathcal{C}_s}\) (see Remark 6.2.1.8). This relationship between derivatives and differentials breaks down when \(S\) is empty: see Examples 6.2.3.3 and 6.2.1.5.

**Example 6.2.3.5.** Let \(\{\mathcal{C}_s\}_{s \in S}\) be a finite collection of \(\infty\)-categories which admit finite colimits and final objects and let \(\mathcal{D}\) be a differentiable \(\infty\)-category. Let \(P_1 : \text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \to \text{Exc}_s(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})\) be a left adjoint to the inclusion (see Proposition 6.1.3.6). If \(F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}\) is a reduced functor, then \(P_1 F\) is also reduced. It follows that the canonical map \(F \to P_1 F\) exhibits \(P_1 F\) as a differential of \(F\). In particular, there exists a differential of \(F\).

We can construct differentials (and derivatives) of more general functors by first passing to the case of reduced functors. For this, we introduce a dual version of Construction 6.1.3.15.
6.2. DIFFERENTIATION

Construction 6.2.3.6. Let \( \{e_s\}_{s \in S} \) be \( \infty \)-categories which admit zero objects \(*_s \in e_s\), and let \( \mathcal{D} \) be an \( \infty \)-category which admits finite colimits and a final object \(*\). For \( 1 \leq i \leq n \), let \( U_i : e_i \to e_i \) denote the constant functor taking the value \(*_i\), and choose a natural transformation of functors \( \alpha_i : U_i \to \text{id}_{e_i} \). For each functor \( F : \prod_{s \in S} e_s \to \mathcal{D} \), consider the functor

\[
\overline{F} : \prod_{s \in S} e_s \times N(P(S)) \xrightarrow{\prod \alpha_i} \prod_{s \in S} e_s \xrightarrow{F} \mathcal{D}
\]

For each \( T \subseteq S \), we let \( F_T \) denote the restriction of \( \overline{F} \) to \( \prod_{s \in S} e_s \times \{T\} \), so that \( F_T \) is given by the formula

\[
F_T(\{X\}) = F(\{X'_i\}) \quad \text{where} \quad X'_i = \begin{cases} X_s & \text{if } s \in T \\ *_s & \text{if } s \notin T. \end{cases}
\]

The functor \( \overline{F} \) determines a natural transformation

\[
\beta : \lim_{T \subseteq S} F_T \to F_S = F.
\]

Let \( * \) denote the constant functor \( \prod_{s \in S} e_s \to \mathcal{D} \) taking the value \(* \in \mathcal{D} \). We let \( \text{cored}(F) \) denote the pushout

\[
\lim_{T \subseteq S} \prod_{T \subseteq S} F_T.
\]

We will refer to \( \text{cored}(F) \) as the coreduction of \( F \).

Remark 6.2.3.7. Let \( F : \prod_{s \in S} e_s \to \mathcal{D} \) be as in Construction 6.2.3.6. If \( S \) is empty, then the canonical map \( F \to \text{cored}(F) \) is an equivalence. Otherwise, \( \text{cored}(F) \) is a left Kan extension of \( F \).

We now prove (b). Let \( G : \prod_{s \in S} e_s \to \mathcal{D} \) be any reduced functor. Then the canonical map \( F \to \text{cored}(F) \) induces a homotopy equivalence

\[
\text{Map}_{\text{Fun}(\prod_{s \in S} e_s, \mathcal{D})}(\text{cored}(F), G) \to \text{Map}_{\text{Fun}(\prod_{s \in S} e_s, \mathcal{D})}(F, G).
\]

Proof. If \( S \) is empty, the result is obvious. Let us therefore assume that \( S \) is nonempty. If \( \mathcal{D} \) is pointed, the desired result follows immediately from Proposition 6.1.3.17. The proof in the general case is similar. Suppose we are given a collection of objects \( \bar{X} = \{X_s \in e_s\}_{s \in S} \) such that some \( X_s \) is a zero object of \( e_s \). Then for \( T \subseteq S \), the canonical map \( F_T(\bar{X}) \to F_{T - \{s\}}(\bar{X}) \) is an equivalence. It follows that the diagram

\[
\{F_T(\bar{X})\}_{T \subseteq S}
\]

is a left Kan extension of \( \{F_T(\bar{X})\}_{J \not\subseteq S} \). This proves (a).

We now prove (b). Let \( G : \prod_{s \in S} e_s \to \mathcal{D} \) be reduced. We have a pullback diagram of mapping spaces

\[
\text{Map}_{\text{Fun}(\prod_{s \in S} e_s, \mathcal{D})}(\text{cored}(F), G) \to \lim_{T \subseteq S} \text{Map}_{\text{Fun}(\prod_{s \in S} e_s, \mathcal{D})}(\bar{X}, G)
\]

\[
\text{Map}_{\text{Fun}(\prod_{s \in S} e_s, \mathcal{D})}(F, G) \to \lim_{T \subseteq S} \text{Map}_{\text{Fun}(\prod_{s \in S} e_s, \mathcal{D})}(F_T, G).
\]
where $\ast$ denotes the constant functor taking the value $\ast \in D$. To prove that the left vertical map is a homotopy equivalence, it suffices to prove that the right vertical map is a homotopy equivalence. For this, we show that for every proper subset $T \subseteq S$, the canonical map $\Map_{\Fun(\prod_{s \in S} C_s, D)}(\ast, G) \Map_{\Fun(\prod_{s \in S} C_s, D)}(F_T, G)$ is a homotopy equivalence. Choose an element $t \in S - T$, and let $\mathcal{C}$ denote the full subcategory of $\prod_{s \in S} C_s$ spanned by those objects whose $t$th coordinate is a zero object of $\mathcal{C}_t$. Then $\ast$ and $F_T$ are both left Kan extensions of their restrictions to $\mathcal{C}$. It will therefore suffice to show that the canonical map

$$\Map_{\Fun(\mathcal{C}, D)}(\ast, G) \Map_{\Fun(\mathcal{C}, D)}(F_T, G)$$

is a homotopy equivalence. This is clear, since $G|\mathcal{C}$ is a final object of $\Fun(\mathcal{C}, D)$. \hfill $\square$

**Corollary 6.2.3.9.** Let $\{\mathcal{C}_s\}_{s \in S}$ be a finite collection of pointed $\infty$-categories, let $D$ an $\infty$-category which admits finite colimits and a final object, and let $\Fun_s(\prod_{s \in S} \mathcal{C}_s, D)$ be the full subcategory of $\Fun(\prod_{s \in S} \mathcal{C}_s, D)$ spanned by the reduced functors. Then the inclusion

$$\Fun_s(\prod_{s \in S} \mathcal{C}_s, D) \to \Fun(\prod_{s \in S} \mathcal{C}_s, D)$$

admits a left adjoint, given by the construction $F \mapsto \text{cored}(F)$.

**Example 6.2.3.10.** Let $F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_n \to D$ be as in Construction 6.2.3.6. Suppose that there exist integers $1 \leq j < k \leq n$ such that, for every sequence of objects $\{X_i \in \mathcal{C}_i\}$, the diagram

$$
\begin{align*}
F(X_1, \ldots, X_{j-1}, \ast_j, X_{j+1}, \ldots, X_{k-1}, \ast_k, X_{k+1}, \ldots, X_n) \\
F(X_1, \ldots, X_{j-1}, \ast_j, X_{j+1}, \ldots, X_n) \\
F(X_1, \ldots, X_{k-1}, \ast_k, X_{k+1}, \ldots, X_n) \\
F(X_1, \ldots, X_n)
\end{align*}
$$

is a pushout square. Then the diagram of functors $\{F_T\}_{T \subseteq S}$ is a left Kan extension of its restriction to $N(\{T \in P(S) : T \cap \{j, k\} \neq \{j, k\}\})$, which contains $N(\{S - \{j\}, S - \{j, k\}, S - \{k\}\})$ as a left cofinal subset. It follows that the map $\beta : \lim_{T \subseteq S} F_T \to F_S = F$ is an equivalence, so that the coreduction $\text{cored}(F)$ is trivial.

**Proposition 6.2.3.11.** Let $\alpha : S \to T$ be a surjective map of finite sets, let $\{\mathcal{C}_s\}_{s \in S}$ and $\{\mathcal{D}_t\}_{t \in T}$ be pointed $\infty$-categories, and let $\mathcal{E}$ be an $\infty$-category which admits finite colimits and a final object. Suppose we are given functors

$$G_t : \prod_{\alpha(s) = t} \mathcal{C}_s \to \mathcal{D}_t \quad F : \prod_{t \in T} \mathcal{D}_t \to \mathcal{E}$$

where each $G_t$ is reduced. Then we have a canonical equivalence $\text{cored}(F \circ \prod_{t \in T} G_t) \simeq \text{cored}(F) \circ \prod_{t \in T} G_t$.

**Proof.** Since each $G_t$ is reduced, the functor $\text{cored}(F) \circ \prod_{t \in T} G_t$ factors as a composition

$$F \circ \prod_{t \in T} G_t \to \text{cored}(F \circ \prod_{t \in T} G_t) \xrightarrow{\beta} \text{cored}(F) \circ \prod_{t \in T} G_t.$$  

We wish to prove that $\beta$ is an equivalence. For this, it will suffice to show that $\text{cored}(F) \circ \prod_{t \in T} G_t$ satisfies the universal property of Proposition 6.2.3.8: that is, for every reduced functor $H : \prod_{s \in S} \mathcal{C}_s \to \mathcal{E}$ induces a homotopy equivalence

$$\theta : \Map_{\Fun(\prod_{s \in S} \mathcal{C}_s, \mathcal{E})}(\text{cored}(F) \circ \prod_{t \in T} G_t, H) \to \Map_{\Fun(\prod_{s \in S} \mathcal{C}_s, \mathcal{E})}(F \circ \prod_{t \in T} G_t, H).$$
Let $\mathcal{E}_*: \prod_{t \in T} \mathbb{D}_t \to \mathcal{E}$ be the constant functor taking the value $* \in \mathcal{E}$, where $*$ is a final object of $\mathcal{E}$. Then $\theta$ is the pullback of a map

$$\lim_{T' \subseteq T} \text{Map}(\prod_{s \in S} \mathbb{E}_s, \mathcal{E})(\mathsf{z} \circ \prod_{t \in T} G_t, H) \to \lim_{T' \subseteq T} \text{Map}(\prod_{s \in S} \mathbb{E}_s, \mathcal{E})(F_{T'} \circ \prod_{t \in T} G_t, H).$$

It will therefore suffice to show that for every proper subset $T' \subset T$, the map

$$\theta_{T'} : \text{Map}(\prod_{s \in S} \mathbb{E}_s, \mathcal{E})(\mathsf{z} \circ \prod_{t \in T} G_t, H) \to \text{Map}(\prod_{s \in S} \mathbb{E}_s, \mathcal{E})(F_{T'} \circ \prod_{t \in T} G_t, H)$$

is a homotopy equivalence. Choose an element $t \in T - T'$, choose an element $\overline{t} \in S$ with $\alpha(\overline{t}) = t$, and let $\mathcal{E} \subseteq \prod_{s \in S} \mathbb{E}_s$ be the full subcategory spanned by those objects whose $\overline{t}$th coordinate is a zero object of $\mathbb{E}_\overline{t}$. Then $F_{T'} \circ \prod_{t \in T} G_t$ and $\mathsf{z} \circ \prod_{t \in T} G_t$ are both left Kan extensions of their restrictions to $\mathcal{E}$. It will therefore suffice to show that the canonical map

$$\text{Map}(\mathcal{E}, \mathcal{E})(\mathsf{z} \circ \prod_{t \in T} G_t)|\mathcal{E}, H|\mathcal{E}) \to \text{Map}(\mathcal{E}, \mathcal{E})(F_{T'} \circ \prod_{t \in T} G_t)|\mathcal{E}, H|\mathcal{E})$$

is a homotopy equivalence. This is clear, since $H|\mathcal{E}$ is a final object of $\text{Fun}(\mathcal{E}, \mathcal{E})$.

**Remark 6.2.3.12.** Let $F : \prod_{s \in S} \mathbb{E}_s \to \mathbb{D}$ be as in Construction 6.2.3.6, and suppose we are given a collection of reduced functors $G_s : \mathbb{E}_s' \to \mathbb{D}'. Then we have a canonical equivalence

$$\text{cored}(F) \circ \prod_{s \in S} G_s \simeq \text{cored}(F \circ \prod_{s \in S} G_s).$$

**Proposition 6.2.3.13.** Let $\{\mathbb{E}_s\}_{s \in S}$ be a finite collection of $\infty$-categories, let $\mathbb{D}$ be a differentiable $\infty$-category which admits finite colimits, and let $F : \prod_{s \in S} \mathbb{E}_s \to \mathbb{D}$ be a functor. Then:

1. If each $\mathbb{E}_s$ admits finite colimits and a zero object, then there exists a differential of $F$.
2. If each $\mathbb{E}_s$ admits finite limits, then there exists a derivative of $F$.

**Proof.** We first prove (1). Set $G = \text{cored}(F)$. If $\beta : G \to G'$ exhibits $G'$ as a differential of $G$, then the composite functor $F \circ G \to F \circ G'$ exhibits $G'$ as a differential of $F$. Consequently, assertion (1) follows from Example 6.2.3.5.

If $S$ is empty, then assertion (2) follows from Example 6.2.1.5 and Proposition 6.2.3.16. Let us now prove (2) in the case where $F$ is nonempty. Using Remark 6.2.1.6, we can replace each $\mathbb{E}_s$ by the $\infty$-category of pointed objects $\mathbb{E}_s$, and thereby reduce to the case where each $\mathbb{E}_s$ is pointed. Let $G = \text{cored}(F)$ as above. If $\alpha : G \circ \prod_{s \in S} \Omega_{\mathbb{D}_s}^\infty \to \Omega_{\mathbb{D}}^\infty \circ g$ exhibits a functor $g : \prod_{s \in S} \text{Sp}(\mathbb{E}_s) \to \text{Sp}(\mathbb{D})$ as a derivative of $G$, then the composite map

$$F \circ \prod_{s \in S} \Omega_{\mathbb{E}_s}^\infty \to G \circ \prod_{s \in S} \Omega_{\mathbb{E}_s}^\infty \to \Omega_{\mathbb{D}}^\infty \circ g$$

exhibits $g$ as a derivative of $F$ (since $G' \circ \prod_{s \in S} \Omega_{\mathbb{D}_s}^\infty$ is a coreduction of $F' \circ \prod_{s \in S} \Omega_{\mathbb{D}_s}^\infty$, by Proposition 6.2.3.11). The desired result now follows from Proposition 6.2.1.9.

**Lemma 6.2.3.14.** Let $\{\mathbb{E}_s\}_{s \in S}$ be a nonempty finite collection of $\infty$-categories which admit finite colimits and final objects, let $\mathbb{D}$ be an $\infty$-category which admits finite colimits and a final object, and let $\mathcal{E}$ be a differentiable $\infty$-category. Let

$$P_1 : \text{Fun}(\mathbb{D}, \mathcal{E}) \to \text{Exc}(\mathbb{D}, \mathcal{E}) \quad P_\mathcal{E} : \text{Fun}(\prod_{s \in S} \mathbb{E}_s, \mathcal{E}) \to \text{Exc}(\prod_{s \in S} \mathbb{E}_s, \mathcal{E})$$

be left adjoints to the inclusion functors, and let $F : \prod_{s \in S} \mathbb{E}_s \to \mathbb{D}$ be a functor which is reduced and right exact in each variable. Then, for every reduced functor $G : \mathbb{D} \to \mathcal{E}$, we have a canonical equivalence $P_\mathcal{E}(G \circ F) \simeq P_1(G) \circ F$. 
Proof. Since $F$ is right exact in each variable and $G$ is excisive, the functor $P_1(G) \circ F$ is excisive in each variable. Consequently, the canonical map $\alpha : G \circ F \to P_1(G) \circ F$ induces a natural transformation $\beta : P_1(G \circ F) \to P_1(G) \circ F$. Let $H : \prod_{s \in S} \mathcal{E}_s \to \mathcal{E}$ be an arbitrary functor, so that composition with $\alpha$ induces a map
\[
\theta : \text{Map}_{\text{Fun}}(\prod_{s \in S} \mathcal{E}_s, \mathcal{E})(P_1(G) \circ F, H) \to \text{Map}_{\text{Fun}}(\prod_{s \in S} \mathcal{E}_s, \mathcal{E})(G \circ F, H).
\]
Fix an element $s \in S$, and regard $F$ as defining a functor
\[
f : \prod_{t \neq s} \mathcal{E}_t \to \text{Fun}(\mathcal{E}_s, \mathcal{D}).
\]
Applying Remark 6.1.1.30, we see that $P_1(G) \circ F$ classifies the functor
\[
\prod_{t \neq s} \mathcal{E}_t \xrightarrow{L} \text{Fun}(\mathcal{E}_s, \mathcal{D}) \xrightarrow{G_0} \text{Fun}(\mathcal{E}_s, \mathcal{E}) \xrightarrow{L} \text{Exc}(\mathcal{E}_s, \mathcal{E}),
\]
where $L : \text{Fun}(\mathcal{E}_s, \mathcal{E}) \to \text{Exc}(\mathcal{E}_s, \mathcal{E})$ denotes a left adjoint to the inclusion. It follows that the natural transformation $\theta$ is an homotopy equivalence whenever $H$ is excisive in the $s$th variable. In particular, it is an equivalence when $H$ is excisive in each variable, so that $\beta$ is an equivalence. \qed

Proposition 6.2.3.15. Let $\alpha : S \to T$ be a surjective map of finite sets. Suppose we are given pointed $\infty$-categories $\{\mathcal{E}_s\}_{s \in S}$, $\{\mathcal{D}_t\}_{t \in T}$ which admit finite colimits, and a differentiable $\infty$-category $\mathcal{E}$ which is pointed and admits finite colimits. Let $\gamma : F \to F'$ be a natural transformation between functors $F, F' : \prod_{t \in T} \mathcal{D}_t \to \mathcal{E}$ which exhibits $F'$ as a differential of $F$, and suppose we are given a collection of functors $G_t : \prod_{\alpha(s) = t} \mathcal{E}_s \to \mathcal{D}_t$ which are right exact in each variable. Then the induced natural transformation
\[
F \circ \prod_{t \in T} G_t \to F' \circ \prod_{t \in T} G_t
\]
exhibits $F' \circ \prod_{t \in T} G_t$ as a differential of $F \circ \prod_{t \in T} G_t$.

Proof. Using Proposition 6.2.3.11 we can replace $F$ by $\text{core}(F)$, and thereby reduce to the case where the functor $F$ is reduced. In this case, the desired result follows from repeated application of Lemma 6.2.3.14. \qed

Under some mild hypotheses, one can show that the derivative and differential of a functor $F : \prod_{s \in S} \mathcal{E}_s \to \mathcal{D}$ are interchangeable data. More precisely, we can recover the differential of $F$ as the composition
\[
\prod_{s \in S} \mathcal{E}_s \xrightarrow{\prod_{s \in S} \Sigma_{s}^{\infty}} \prod_{s \in S} \text{Sp}(\mathcal{E}_s) \xrightarrow{\beta_F} \text{Sp}(\mathcal{D}) \xrightarrow{\Omega_{\mathcal{E}}^{\infty}} \mathcal{D},
\]
where $\Sigma_{s}^{\infty}$ denotes a left adjoint to the functor $\Omega_{\mathcal{E}}^{\infty}$. We begin by studying some existence criteria for the functors $\Sigma_{s}^{\infty}$.

Proposition 6.2.3.16. Let $\mathcal{E}$ be a differentiable $\infty$-category which admits finite colimits. Then the functor $\Omega^{\infty} : \text{Sp}(\mathcal{E}) \to \mathcal{E}$ admits a left adjoint.

**Definition 6.2.3.17.** Let $\mathcal{E}$ be a differentiable $\infty$-category which admits finite colimits. We let $\Sigma^{\infty} : \mathcal{E} \to \text{Sp}(\mathcal{E})$ denote a left adjoint to the functor $\Omega^{\infty} : \text{Sp}(\mathcal{E}) \to \mathcal{E}$. We will refer to $\Sigma^{\infty}$ as the **infinite suspension** functor. In the special case where the $\infty$-category $\mathcal{E}$ is pointed, we will denote the functor $\Sigma^{\infty}$ simply by $\Sigma^\infty$ (or by $\Sigma_{+}^{\infty}$, if we wish to emphasize the dependence on $\mathcal{E}$).

**Remark 6.2.3.18.** The notation of Definition 6.2.3.17 is consistent with that of Proposition 1.4.4.4, in the special case where $\mathcal{E}$ is a presentable $\infty$-category.

The proof of Proposition 6.2.3.16 is based on the following lemma:
Lemma 6.2.3.19. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and a final object, and let \( \theta : \text{Fun}_*(S_*^{\text{fin}}, \mathcal{C}) \to \mathcal{C} \) be the functor given by evaluation on the 0-sphere \( S^0 \in S_*^{\text{fin}} \). Then \( \theta \) admits a left adjoint \( \Sigma^\infty : \mathcal{C} \to \text{Fun}_*(S_*^{\text{fin}}, \mathcal{C}) \).

Proof. Let \( \text{Fun}^{\text{Rex}}(S_*^{\text{fin}}, \mathcal{C}) \) denote the full subcategory of \( \text{Fun}(S_*^{\text{fin}}, \mathcal{C}) \) spanned by the right exact functors, so that evaluation on the one-point space \( * \in S_*^{\text{fin}} \) induces a trivial Kan fibration \( \text{Fun}^{\text{Rex}}(S_*^{\text{fin}}, \mathcal{C}) \to \mathcal{C} \) (see Remark 1.4.2.5). Choose a section of this trivial Kan fibration, which we will denote by \( f_\gamma \). Unwinding the definitions, we wish to prove that the canonical map

\[
\text{Map}_{\text{Fun}(S_*^{\text{fin}}, \mathcal{C})}(f_\gamma, g) \to \text{Map}_{\mathcal{C}}(f_\gamma, g(S^0)) \to \text{Map}_{\mathcal{C}}(g(S^0))
\]

which determines a natural transformation \( u : \text{id} \to \theta \circ \Sigma^\infty \). We claim that \( u \) is the unit map for an adjunction between \( \theta \) and \( F \). To prove this, fix an object \( C \in \mathcal{C} \) and a reduced functor \( g : S_*^{\text{fin}} \to \mathcal{C} \); we wish to show that \( u \) induces a homotopy equivalence

\[
\text{Map}_{\text{Fun}(S_*^{\text{fin}}, \mathcal{C})}(f_\gamma, g) \to \text{Map}_{\mathcal{C}}(f_\gamma, S^0) \to \text{Map}_{\mathcal{C}}(g(S^0)).
\]

Note that if \( h : S_*^{\text{fin}} \to \mathcal{C} \) is a constant functor, then \( h \) is a left Kan extension of its restriction to the final object of \( S_*^{\text{fin}} \). Since \( g \) is reduced, we deduce that \( \text{Map}_{\text{Fun}(S_*^{\text{fin}}, \mathcal{C})}(h, g) \) is contractible. Let \( \phi : S_*^{\text{fin}} \to S_*^{\text{fin}} \) be the forgetful functor. We then have a pullback diagram of functors

\[
\begin{array}{ccc}
C & \to & * \\
\downarrow & & \downarrow \\
f_\gamma \circ \phi & \to & f_\gamma \circ \phi
\end{array}
\]

where \( C : S_*^{\text{fin}} \to \mathcal{C} \) denotes the constant functor taking the value \( C \) and \( * \) is defined similarly. It follows that the restriction map \( \text{Map}_{\text{Fun}(S_*^{\text{fin}}, \mathcal{C})}(f_\gamma, g) \to \text{Map}_{\mathcal{C}}(f_\gamma, g(S^0)) \) is a homotopy equivalence. Note that \( \phi \) admits a left adjoint \( \psi \), which carries each finite space \( K \) to the space obtained from \( K \) by adding a disjoint base point. Unwinding the definitions, we wish to prove that the canonical map

\[
\text{Map}_{\text{Fun}(S_*^{\text{fin}}, \mathcal{C})}(f_\gamma, g) \simeq \text{Map}_{\mathcal{C}}(f_\gamma, S^0) \to \text{Map}_{\mathcal{C}}(g(S^0))
\]

is a homotopy equivalence. This follows from the fact that \( f_\gamma \) is a left Kan extension of its restriction along the inclusion \( \{ * \} \to S_*^{\text{fin}} \).

Proof of Proposition 6.2.3.16. The functor \( \Omega^\infty \) factors as a composition

\[
\text{Sp}(\mathcal{C}) \hookrightarrow \text{Fun}_*(S_*^{\text{fin}}, \mathcal{C}) \xrightarrow{\theta} \mathcal{C},
\]

where \( \theta \) is given by evaluation at \( S^0 \in S_*^{\text{fin}} \). The desired result now follows from Proposition 6.2.1.9 and Lemma 6.2.3.19.

Remark 6.2.3.20. Let \( S \) be a nonempty finite set and let \( \mathcal{D} \) be a differentiable \( \infty \)-category which admits finite colimits, and let \( L_\theta^S : \text{Fun}_*(\bigoplus_{s \in S} S_*^{\text{fin}}, \mathcal{D}) \to \text{Exc}_s(\bigoplus_{s \in S} S_*^{\text{fin}}, \mathcal{D}) \) be a left adjoint to the inclusion (see Construction 6.2.1.14). Then the inclusion \( \text{Fun}(\bigoplus_{s \in S} S_*^{\text{fin}}, \mathcal{D}) \to \text{Exc}_s(\bigoplus_{s \in S} S_*^{\text{fin}}, \mathcal{D}) \) admits a left adjoint, given by \( X \mapsto L_\theta^S \text{cored}(X) \).
Now suppose we are given a collection of pointed differentiable ∞-categories \( \{ C_s \}_{s \in S} \). For each functor \( F : \prod_{s \in S} C_s \to D \), let \( F^+ : \prod_{s \in S} \text{Fun}(\delta^\text{fin}_s, C) \to \text{Fun}(\prod_{s \in S} \delta^\text{fin}_s, D) \) be the functor given by composition with \( F \). For every collection of reduced functors \( X_s \in \text{Fun}(\delta^\text{fin}_s, C) \), Proposition 6.2.3.11 supplies an equivalence \( \text{cored}(F^+ (\{ X_s \})) \simeq \text{cored}(F)^+ (\{ X_s \}) \). Combining this observation with Proposition 6.2.1.19, we see that differential \( \partial F \simeq \partial \text{cored}(F) \) is given by the composition

\[
\prod_{s \in S} \text{Sp}(C_s) \hookrightarrow \prod_{s \in S} \text{Fun}(\delta^\text{fin}_s, C_s) \xrightarrow{F^+} \text{Fun}(\prod_{s \in S} \delta^\text{fin}_s, D) \to \text{Exc}_*(\prod_{s \in S} \delta^\text{fin}_s, D),
\]

where the last functor is a left adjoint to the inclusion.

The main result of this section is the following:

**Theorem 6.2.3.21.** Let \( \{ C_s \}_{s \in S} \) be a finite collection of pointed differentiable ∞-categories which admit finite colimits, and let \( D \) be a differentiable ∞-category. Then composition with the functors \( \Sigma^\infty_{C_s} : C_s \to \text{Sp}(C_s) \) induces an equivalence of ∞-categories

\[
\text{Exc}_*(\prod_{s \in S} \text{Sp}(C_s), D) \to \text{Exc}_*(\prod_{s \in S} C_s, D).
\]

Before giving the proof of Theorem 6.2.3.21, let us describe some of its consequences.

**Corollary 6.2.3.22.** Let \( \{ C_s \}_{s \in S} \) be a nonempty finite collection of pointed differentiable ∞-categories which admit finite colimits and let \( D \) be a differentiable ∞-category. Then the construction \( f \mapsto \Omega^\infty_D \circ f \circ \prod_{s \in S} \Sigma^\infty_{C_s} \) induces an equivalence of ∞-categories \( \phi : \text{Exc}_*(\prod_{s \in S} \text{Sp}(C_s), \text{Sp}(D)) \to \text{Exc}_*(\prod_{s \in S} C_s, D) \).

**Proof.** Using Theorem 6.2.3.21, we are reduced to proving that composition with \( \Omega^\infty_D \) induces an equivalence of ∞-categories

\[
\theta : \text{Exc}_*(\prod_{s \in S} C_s, \text{Sp}(D)) \to \text{Exc}_*(\prod_{s \in S} D).
\]

This follows from Proposition 1.4.2.22 together with the following assertion:

\((*)\) Let \( C \) be an ∞-category which admits countable colimits and let \( F : C \to \text{Sp}(D) \) be an excisive functor.

Then \( F \) preserves sequential colimits if and only if the functor \( \Omega^\infty_D \circ F \) preserves sequential colimits.

The “only if” direction is obvious, since the functor \( \Omega^\infty_D \) preserves sequential colimits (see Example 6.2.1.17). Conversely, suppose that \( \Omega^\infty_D \circ F \) preserves sequential colimits; we wish to prove that \( F \) preserves sequential colimits. Using Remark 1.4.2.25, we are reduced to proving that for each \( n \geq 0 \), the functor \( \Omega^\infty_D \circ F \simeq \Omega^\infty_D (\Sigma^n_D \circ \text{Sp}(D) \circ F) \) commutes with sequential colimits. Since \( F \) is excisive, we can rewrite this functor as \( \Omega^\infty_D \circ F \circ \Sigma^n_C \), which commutes with \( \Sigma^n_C \)-categories by virtue of the fact that the functors \( \Omega^\infty_D \circ F \) and \( \Sigma^n_C \) commute with sequential colimits.

**Remark 6.2.3.23.** In the situation of Corollary 6.2.3.22, one can give a homotopy inverse to \( \phi \) explicitly by the construction \( F \mapsto \partial F \). To see this, it suffices to show that for \( f \in \text{Exc}_*(\prod_{s \in S} \text{Sp}(C_s), \text{Sp}(D)) \), the canonical map

\[
\alpha : \Omega^\infty_D \circ f \circ \prod_{s \in S} \Sigma^\infty_{C_s} \circ \prod_{s \in S} \Omega^\infty_{C_s} \to \Omega^\infty_D \circ f
\]

exhibits \( f \) as a derivative of \( F = \Omega^\infty_D \circ f \circ \prod_{s \in S} \Sigma^\infty_{C_s} \). Since \( f \) is multilinear, it suffices to show that for each multilinear functor \( g : \prod_{s \in S} \text{Sp}(C_s) \to \text{Sp}(D) \), the map

\[
\text{Map}_\text{Fun}(\prod_{s \in S} \text{Sp}(C_s), \text{Sp}(D))(\Omega^\infty_D \circ f, g) \to \text{Map}_\text{Fun}(\prod_{s \in S} \text{Sp}(C_s), \text{Sp}(D))(\Omega^\infty_D \circ f \circ \prod_{s \in S} \Sigma^\infty_{C_s} \circ \prod_{s \in S} \Omega^\infty_{C_s}, g)
\]

\[
\to \text{Map}_\text{Fun}(\prod_{s \in S} C_s, \text{Sp}(D))(\Omega^\infty_D \circ f \circ \prod_{s \in S} \Sigma^\infty_{C_s} \circ \prod_{s \in S} \Omega^\infty_{C_s}, g)
\]

is a homotopy equivalence. This follows from Theorem 6.2.3.21.
Corollary 6.2.3.24. Let \( \{ \mathscr{C}_s \}_{s \in S} \) be a nonempty finite collection of pointed differentiable \( \infty \)-categories which admit finite colimits, let \( \mathcal{D} \) be a differentiable \( \infty \)-category, and suppose we are reduced functors

\[
F : \prod_{s \in S} \mathscr{C}_s \to \mathcal{D} \quad f : \prod_{s \in S} \text{Sp}(\mathscr{C}_s) \to \text{Sp}(\mathcal{D})
\]

where \( F \) preserves sequential colimits and \( f \) is exact in each variable. Let \( \alpha : F \circ \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \to \mathcal{D} \circ f \) be a natural transformation. The following conditions are equivalent:

(a) The natural transformation \( \alpha \) exhibits \( f \) as a derivative of \( F \).

(b) The composite transformation

\[
\beta : F \to F \circ \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \circ \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \circ \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \circ \prod_{s \in S} \text{Sp}(\mathcal{C}_s)
\]

exhibits \( \mathcal{D} \circ f \circ \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \) as a differential of \( f \).

Remark 6.2.3.25. In the situation of Corollary 6.2.3.24, suppose that the \( \infty \)-category \( \mathcal{D} \) admits finite colimits, so that the functor \( \prod_{s \in S} \text{Sp}(\mathcal{C}_s) \to \mathcal{D} \) admits a left adjoint \( \text{Sp}(\mathcal{C}_s) \to \mathcal{D} \) (Proposition 6.2.3.16). Using Proposition 1.4.2.22, we obtain the following additional variantions on (a) and (b):

(c) The composite transformation

\[
\gamma : \text{Sp}(\mathcal{C}_s) \to \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s)
\]

exhibits \( \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \) as a differential of \( \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \).

(d) The composite transformation

\[
\delta : \text{Sp}(\mathcal{C}_s) \to \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s)
\]

exhibits \( \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \) as a differential of the functor \( \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \circ \text{Sp}(\mathcal{C}_s) \).

In this situation, we will sometimes abuse terminology by saying that any of the natural transformations \( \beta \), \( \gamma \), and \( \delta \) exhibits \( f \) as a derivative of \( F \).

Theorem 6.2.3.21 is a close relative of Corollary 1.4.4.5. In fact, it is possible to deduce Theorem 6.2.3.21 from Corollary 1.4.4.5, by replacing the \( \infty \)-categories \( \mathcal{C}_s \) by \( \text{Ind}_\kappa(\mathcal{C}_s) \), where \( \kappa \) denotes the least uncountable cardinal. However, we will give a more direct proof which is based on the following lemma:

Lemma 6.2.3.26. Let \( \mathcal{C} \) be a pointed differentiable \( \infty \)-category which admits finite colimits, and let \( \mathcal{X} \) be a stable subcategory of \( \text{Sp}(\mathcal{C}) \) which contains the essential image of the functor \( \text{Sp}(\mathcal{C}) : \mathcal{C} \to \text{Sp}(\mathcal{C}) \). If \( \mathcal{X} \) is closed under sequential colimits, then \( \mathcal{X} = \text{Sp}(\mathcal{C}) \).

Proof. Example 6.2.1.4 implies that the identity functor \( \text{id}_{\text{Sp}(\mathcal{C})} \) is a derivative of the identity functor \( \text{id}_\mathcal{C} \). It follows that the counit map \( \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \to \text{id}_{\text{Sp}(\mathcal{C})} \) exhibits \( \text{id}_{\text{Sp}(\mathcal{C})} \) as the 1-excise approximation to \( \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \); that is, the identity functor \( \text{id}_{\text{Sp}(\mathcal{C})} \) is given by the colimit

\[
\lim_{n \to \infty} \Omega_\mathcal{C}^n \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C})
\]

In particular, for every spectrum object \( X \in \text{Sp}(\mathcal{C}) \), we have a canonical equivalence

\[
X \simeq \lim_{n \to \infty} \Omega_\mathcal{C}^n \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C})
\]

Since \( \mathcal{X} \) contains the essential image of \( \text{Sp}(\mathcal{C}) \) and is closed under desuspension, it contains each of the objects \( \Omega_\mathcal{C}^n \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \circ \text{Sp}(\mathcal{C}) \). Using the fact that that \( \mathcal{X} \) is closed under sequential colimits, we deduce that \( X \in \mathcal{X} \). \qed
Proof of Theorem 6.2.3.21. Working separately in each argument, we are reduced to proving the following assertion:

(*) Let $\mathcal{C}$ be a pointed differentiable $\infty$-category which admits finite colimits and $\mathcal{D}$ an arbitrary differentiable $\infty$-category. Then composition with the functor $\Sigma^\infty_{\mathcal{C}}$ induces an equivalence of $\infty$-categories

$$\text{Exc}_*(\text{Sp}(\mathcal{C}), \mathcal{D}) \rightarrow \text{Exc}_*(\mathcal{C}, \mathcal{D}).$$

Let $\phi : \text{Exc}_*(\text{Sp}(\mathcal{C}), \mathcal{D}) \rightarrow \text{Fun}(\mathcal{C}, \mathcal{D})$ denote the functor given by precomposition with $\Sigma^\infty_{\mathcal{C}}$, and write $\phi$ as a composition of functors

$$\text{Exc}_*(\text{Sp}(\mathcal{C}), \mathcal{D}) \rightarrow \text{Fun}_*(\text{Sp}(\mathcal{C}), \mathcal{D}) \circ \Sigma^\infty_{\mathcal{C}} \rightarrow \text{Fun}_*(\mathcal{C}, \mathcal{D}).$$

Each of these functors admits a left adjoint; it follows that $\phi$ admits a left adjoint $\psi$, given by the composition

$$\text{Exc}_*(\text{Sp}(\mathcal{C}), \mathcal{D}) \overset{\phi_0}{\underset{\phi_0}{\longrightarrow}} \text{Exc}_*(\text{Sp}(\mathcal{C}), \mathcal{D}) \circ \Sigma^\infty_{\mathcal{C}} \rightarrow \text{Fun}_*(\mathcal{C}, \mathcal{D}),$$

which is given by $F \mapsto \Omega_{\mathcal{D}}^\infty \circ \partial F$. Since the functor $\Sigma^\infty_{\mathcal{C}}$ is right exact, the functor $\phi$ factors through $\text{Exc}_*(\mathcal{C}, \mathcal{D})$. We therefore obtain an adjunction

$$\text{Exc}_*(\mathcal{C}, \mathcal{D}) \overset{\psi_0}{\underset{\psi_0}{\longrightarrow}} \text{Exc}_*(\text{Sp}(\mathcal{C}), \mathcal{D})$$

We wish to show that these functors are mutually inverse equivalences of categories. We begin by showing that the functor $\psi_0$ is fully faithful. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a reduced, excisive functor which commutes with sequential colimits; we wish to show that the unit map

$$u_F : F \rightarrow \phi_0 \psi_0 F = \Omega_{\mathcal{D}}^\infty \circ \partial F \circ \Sigma^\infty_{\mathcal{C}}$$

is an equivalence. Fix an object $C \in \mathcal{C}$; we wish to show that $u_F$ induces an equivalence $u_F(C) : F(C) \rightarrow \Omega_{\mathcal{D}}^\infty \circ \partial F \circ \Sigma^\infty_{\mathcal{C}}(C)$. Let $L_C : \text{Fun}_*(\mathcal{S}_{\mathcal{C}}^\infty, \mathcal{C}) \rightarrow \text{Sp}(\mathcal{C})$ and $L_D : \text{Fun}_*(\mathcal{S}_{\mathcal{D}}^\infty, \mathcal{D}) \rightarrow \text{Sp}(\mathcal{D})$ be left adjoints to the inclusion, and let $F^+ : \text{Fun}_*(\mathcal{S}_{\mathcal{D}}^\infty, \mathcal{C}) \rightarrow \text{Fun}_*(\mathcal{S}_{\mathcal{D}}^\infty, \mathcal{D})$ be the functor given by pointwise composition with $F$, and let $\Sigma^\infty_{\mathcal{C}} : \mathcal{C} \rightarrow \text{Fun}_*(\mathcal{S}_{\mathcal{C}}^\infty, \mathcal{C})$ be a left adjoint to the functor given by evaluation on $S^0 \in \mathcal{S}_{\mathcal{C}}$. Then $\Sigma^\infty_{\mathcal{C}} \simeq L_C \circ \Sigma^\infty_{\mathcal{C}}$. Applying Propositions 6.2.1.19 and 6.2.1.20, we obtain equivalences

$$\partial F(\Sigma^\infty_{\mathcal{C}}(C)) \simeq L_D F^+(\Sigma^\infty_{\mathcal{C}}(C)) \simeq L_D F^+ (\Sigma^\infty_{\mathcal{C}}(C)).$$

Combining this with Remark 6.2.1.13, we obtain an equivalence

$$(\Omega_{\mathcal{D}}^\infty \circ \partial F \circ \Sigma^\infty_{\mathcal{C}}) \simeq (\Omega_{\mathcal{D}}^\infty \circ L_D) F^+(\Sigma^\infty_{\mathcal{C}}(C)) \simeq \lim_n \Omega_{\mathcal{D}}^n (F^+(\Sigma^\infty_{\mathcal{C}}(C))(S^n)) \simeq \lim_n \Omega_{\mathcal{D}}^n F(\Sigma^\infty_{\mathcal{C}}(C)) \simeq (P_1 F)(C).$$

Under this equivalence, the $u_F(C)$ corresponds to the canonical map from $F(C)$ to $(P_1 F)(C)$, which is an equivalence by virtue of our assumption that $F$ is excisive.

To complete the proof that $\phi_0$ and $\psi_0$ are mutually inverse equivalences of $\infty$-categories, it will suffice to show that the functor $\phi_0$ is conservative. Let $\beta : f \rightarrow g$ be a morphism in $\text{Exc}_*(\text{Sym}(\mathcal{C}), \mathcal{D})$ which induces an equivalence $f \circ \Sigma^\infty_{\mathcal{C}} \rightarrow g \circ \Sigma^\infty_{\mathcal{C}}$; we wish to show that $\beta$ is an equivalence. Using Proposition 1.4.2.22, we can replace $\mathcal{D}$ by $\text{Sp}(\mathcal{D})$ and thereby reduce to the case where $\mathcal{D}$ is stable, so that $f$ and $g$ are exact functors. Let $\mathcal{X} \subseteq \text{Sp}(\mathcal{C})$ denote the full subcategory spanned by those objects $X$ for which $\beta$ induces an equivalence $\beta_X : f(X) \rightarrow g(X)$ in $\mathcal{D}$. Since $f$ and $g$ are exact functors which commute with sequential colimits, $\mathcal{X}$ is a stable subcategory of $\text{Sp}(\mathcal{C})$ which is closed under sequential colimits. Since $\mathcal{X}$ contains the essential image of the functor $\Sigma^\infty_{\mathcal{C}}$, we conclude from Lemma 6.2.3.26 that $\mathcal{X} = \text{Sp}(\mathcal{C})$.

In Example 6.2.1.4, we saw that the derivative of a left exact functor has a simple description. We conclude this section by establishing an analogue for right exact functors:
6.2. DIFFERENTIATION

Proposition 6.2.3.27. Let \( \{C_s\}_{s \in S} \) and \( \mathcal{D} \) be pointed differentiable \( \infty \)-categories which admit finite colimits, and suppose we are given functors

\[
F : \prod_{s \in S} C_s \to \mathcal{D} \quad \text{and} \quad f : \prod_{s \in S} \text{Sp}(C_s) \to \text{Sp}(\mathcal{D})
\]

which preserve countable colimits in each variable. Then a natural transformation \( \delta : \Sigma^\infty_\mathcal{D} \circ F \to f \circ \prod_{s \in S} \Sigma^\infty_{C_s} \) exhibits \( f \) as a derivative of \( F \) (see Remark 6.2.3.25) if and only if \( \delta \) is an equivalence.

Proof. Note that the hypotheses guarantee that \( F \) is reduced. Let

\[
F^+ : \prod_{s \in S} \text{Fun}_a(S^\text{fin}, C_s) \to \text{Fun}_a(\prod_{s \in S} S^\text{fin}_s, D)
\]

and \( L^S_{\mathcal{D}} : \text{Fun}_a(\prod_{s \in S} S^\text{fin}_s, \mathcal{D}) \to \text{Sp}(\mathcal{D}) \) be defined as in Construction 6.2.1.14, let \( L_{C_s} : \text{Fun}_a(S^\text{fin}, C_s) \to \text{Sp}(C_s) \) be left adjoints to the inclusion functors, and let \( \Sigma^\infty_{C_s} \) be defined as in Lemma 6.2.3.19. Repeated application of Lemma 6.2.3.19 shows that the functor \( \text{Fun}(\prod_{s \in S} S^\text{fin}_s, \mathcal{D}) \to \mathcal{D} \) given by evaluation at \((S^0, \ldots, S^0)\) admits a left adjoint \( U \). Moreover, we have a canonical equivalence \( U \circ F \simeq F^+ \circ \prod_{s \in S} \Sigma^\infty_{C_s} \). Using Propositions 6.2.1.20 and 6.2.1.19, we obtain equivalences

\[
\Sigma^\infty_\mathcal{D} \circ F \simeq L^S_{\mathcal{D}} \circ U \circ F \\
\simeq L^S_{\mathcal{D}} \circ F^+ \circ \prod_{s \in S} \Sigma^\infty_{C_s} \\
\simeq L^S_{\mathcal{D}} \circ F^+ \circ \prod_{s \in S} L_{C_s} \circ \prod_{s \in S} \Sigma^\infty_{C_s} \\
\simeq L^S_{\mathcal{D}} \circ F^+ \circ \prod_{s \in S} \Sigma^\infty_{C_s} \\
\simeq \tilde{\partial} F \circ \prod_{s \in S} \Sigma^\infty_{C_s}.
\]

This proves the “if” direction of our assertion.

Conversely, suppose that \( \delta \) is an equivalence. Let \( \tilde{\partial} F \) be a derivative of \( F \). Since \( f \circ \Sigma^\infty_{C} \) is excisive, Corollary 6.2.3.24 implies that \( \delta \) factors as a composition

\[
\Sigma^\infty_\mathcal{D} \circ F \overset{\delta'}{\to} \tilde{\partial} F \circ \prod_{s \in S} \Sigma^\infty_{C_s} \overset{\delta''}{\to} f \circ \prod_{s \in S} \Sigma^\infty_{C_s},
\]

where \( \delta' \) exhibits \( \tilde{\partial} F \) as a derivative of \( F \). The first part of the proof shows that \( \delta' \) is an equivalence, so that \( \delta'' \) is an equivalence by the two-out-of-three property. It follows that \( \delta \) exhibits \( f \) as a derivative of \( F \).

Example 6.2.3.28. Let \( F : S^n \to \text{Sp} \) be the functor given by

\[
F(X_1, \ldots, X_n) = \prod X_i.
\]

For \( n \geq 1 \), the functor \( \text{cored}(F) \) is given by the iterated smash product

\[
\text{cored}(F)(X_1, \ldots, X_n) = X_1 \wedge \cdots \wedge X_n.
\]

Since the suspension spectrum functor \( \Sigma^\infty : \text{Sp} \to \text{Sp} \) is symmetric monoidal, we have a commutative diagram

\[
\begin{array}{ccc}
S^n & \xrightarrow{\Sigma^\infty} & \text{Sp}^n \\
\wedge & \Downarrow & \Downarrow \\
S & \xrightarrow{\Sigma^\infty} & \text{Sp}.
\end{array}
\]
Applying Proposition 6.2.3.27, we can identify the derivative $\bar{\partial}(F) \simeq \bar{\partial}(\text{cored}(F))$ with the iterated smash product functor $\otimes : \text{Sp}^n \to \text{Sp}$.

**Variant 6.2.3.29.** Let $F : S^n \to S$ be the functor given by the Cartesian product. If $n \geq 1$, then we can use Remark 6.2.1.6, Remark 6.2.1.7, and Example 6.2.3.28 to identify the derivative $\bar{\partial}(F)$ with the iterated smash product functor $\otimes : \text{Sp}^n \to \text{Sp}$. This description is also correct in the case $n = \infty$. Example 6.2.1.5 allows us to identify $\bar{\partial}(F)$ with the sphere spectrum $S = \Sigma^\infty_+(*$) (which is the unit object for the smash product monoidal structure on Sp).

### 6.2.4 Generalized Smash Products

Let $\text{Sp} = \text{Sp}(S)$ denote the $\infty$-category of spectra. In §4.8.2, we showed that Sp admits a symmetric monoidal structure, with tensor product $\otimes : \text{Sp} \times \text{Sp} \to \text{Sp}$ given by the classical smash product of spectra. Our goal in this section is to address the following question:

**Question 6.2.4.1.** Let $\mathcal{C}$ be an $\infty$-category which admits finite limits, and let $\text{Sp}(\mathcal{C})$ denote the $\infty$-category of spectrum objects of $\mathcal{C}$. Can we equip the $\infty$-category $\text{Sp}(\mathcal{C})$ with some sort of smash product operation, generalizing the classical smash product of spectra?

We will attempt to answer Question 6.2.4.1 using the calculus of functors (more precisely, using the theory of derivatives developed in §6.1). According to Variant 6.2.3.29, the smash product functor $\otimes : \text{Sp} \times \text{Sp} \to \text{Sp}$ can be identified with the derivative of the Cartesian product functor $S \times S \to S$. This suggests the following generalization:

**Definition 6.2.4.2.** Let $\mathcal{C}$ be a differentiable $\infty$-category which admits finite colimits. We define $\otimes : \text{Sp}(\mathcal{C}) \times \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{C})$ to be the derivative of the Cartesian product functor $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$.

Let us now study the properties of the tensor product functor $\otimes : \text{Sp}(\mathcal{C}) \times \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{C})$. By construction, it is exact in each variable (in fact, it even preserves countable colimits separately in each variable). Moreover, it is evidently symmetric: that is, we have canonical equivalences $X \otimes Y \simeq Y \otimes X$, depending functorially on $X, Y \in \text{Sp}(\mathcal{C})$. The matter of associativity is more subtle. Consider the functors

$$F, G : \text{Sp}(\mathcal{C}) \times \text{Sp}(\mathcal{C}) \times \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{C}),$$

given by $F(X, Y, Z) = X \otimes (Y \otimes Z)$, $G(X, Y, Z) = (X \otimes Y) \otimes Z$. By construction, for every pair of spectrum objects $X, Y \in \text{Sp}(\mathcal{C})$, we have a canonical map

$$\alpha_{X,Y} : \Omega_c^\infty(X) \times \Omega_c^\infty(Y) \to \Omega_c^\infty(X \otimes Y),$$

depending functorially on $X$ and $Y$. We therefore obtain maps

$$\beta_{X,Y,Z} : \Omega_c^\infty(X) \times \Omega_c^\infty(Y) \times \Omega_c^\infty(Z) \xrightarrow{\alpha_{X,Y} \times \text{id}} \Omega_c^\infty(X \otimes Y) \otimes \Omega_c^\infty(Z) \xrightarrow{\text{id} \times \beta} \Omega_c^\infty(F(X, Y, Z)),$$

$$\gamma_{X,Y,Z} : \Omega_c^3(X) \times \Omega_c^\infty(Y) \times \Omega_c^\infty(Z) \xrightarrow{\alpha_{X,Y} \times \text{id}} \Omega_c^\infty(X \otimes Y) \otimes \Omega_c^\infty(Z) \xrightarrow{\text{id} \times \gamma} \Omega_c^\infty(G(X, Y, Z)).$$

Let $\otimes^3 : \text{Sp}(\mathcal{C}) \times \text{Sp}(\mathcal{C}) \times \text{Sp}(\mathcal{C}) \to \text{Sp}(\mathcal{C})$ denote the derivative of the three-fold Cartesian product functor $\mathcal{C} \times \mathcal{C} \times \mathcal{C} \to \mathcal{C}$. Since the functors $F$ and $G$ are exact in each variable, $\beta$ and $\gamma$ determine natural transformations $F \xrightarrow{\beta'} \otimes^3 \xrightarrow{\gamma'} G$. In particular, for every triple of spectrum objects $X, Y, Z \in \text{Sp}(\mathcal{C})$, we have maps

$$X \otimes (Y \otimes Z) \xrightarrow{\otimes^3} \{X, Y, Z\} \to (X \otimes Y) \otimes Z.$$

In the special case where $\mathcal{C} = S$, these maps are equivalences, and determine an associativity constraint $X \otimes (Y \otimes Z) \simeq (X \otimes Y) \otimes Z$. However, this depends crucially on special properties of the $\infty$-category of spaces (specifically, the fact that the formation of Cartesian products commutes with colimits in each variable). In general, the tensor product functor of Definition 6.2.4.2 is not associative; however, we can regard the functor $\otimes^3$ and the natural transformations $\beta'$ and $\gamma'$ as providing a weak form of the associative law. To discuss this type of structure more systematically, it will be convenient to introduce the following definition:
**Definition 6.2.4.3.** Let \( p : \mathcal{O} \rightarrow N(\mathcal{F}_{\text{fin}}) \) be an \( \infty \)-operad. We will say that \( \mathcal{O} \) is **corepresentable** if the map \( p \) is a locally coCartesian fibration.

**Remark 6.2.4.4.** Let \( p : \mathcal{O} \rightarrow N(\mathcal{F}_{\text{fin}}) \) be a corepresentable \( \infty \)-operad. For \( n \geq 0 \), the unique active morphism \( \langle n \rangle \rightarrow \langle 1 \rangle \) in \( \mathcal{F}_{\text{fin}} \) induces a functor

\[
\mathcal{O}^n \simeq \mathcal{O}^\langle n \rangle \rightarrow \mathcal{O}^\langle 1 \rangle = \mathcal{O},
\]

which we will denote by \( \{X_i\}_{1 \leq i \leq n} \mapsto \otimes^n \{X_i\} \). Since this construction is \( \Sigma_n \)-equivariant, it can be described more invariantly: for every finite set \( I \), we obtain a tensor product functor \( \otimes^I : \mathcal{O}^I \rightarrow \mathcal{O} \).

**Remark 6.2.4.5.** Let \( p : \mathcal{O} \rightarrow N(\mathcal{F}_{\text{fin}}) \) be an \( \infty \)-operad. Then \( p \) is corepresentable if and only if it satisfies the following conditions:

(* For every finite collection of objects \( \{X_i\}_{i \in I} \) of \( \mathcal{O} \), there exists an object \( Y \in \mathcal{O} \) and an operation \( \phi \in \text{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y) \) which is universal in the following sense: for every object \( Z \in \mathcal{O} \), composition with \( \phi \) induces a homotopy equivalence \( \text{Map}_\mathcal{O}(Y, Z) \rightarrow \text{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Z) \). Here \( Y = \otimes \{X_i\}_{i \in I} \), where \( \otimes \) denotes the functor of Remark 6.2.4.4.

**Remark 6.2.4.6.** Let \( \mathcal{O} \) be a corepresentable \( \infty \)-operad. The 0-fold tensor product \( \otimes^0 : \Delta^0 \simeq \mathcal{O} \rightarrow \mathcal{O} \) can be identified with an object \( E \in \mathcal{O} \). Note that \( \mathcal{O} \) is a unital \( \infty \)-operad (in the sense of Definition 2.3.1.1) if and only if \( E \) is an initial object of \( \mathcal{O} \).

**Remark 6.2.4.7.** Let \( p : \mathcal{O} \rightarrow N(\mathcal{F}_{\text{fin}}) \) be a corepresentable \( \infty \)-operad. Then the underlying \( \infty \)-category \( \mathcal{O} \) is equipped with a tensor product operation \( \otimes : \mathcal{O} \times \mathcal{O} \rightarrow \mathcal{O} \), given by the functor \( \otimes^2 \) of Remark 6.2.4.4. The tensor product \( \otimes \) is commutative (up to canonical equivalence), but is generally not associative. To every triple of objects \( X, Y, Z \in \mathcal{O} \), the locally coCartesian fibration \( \mathcal{O} \rightarrow N(\mathcal{F}_{\text{fin}}) \) associates a 3-fold tensor product \( \otimes^3 \{X, Y, Z\} \), which is equipped with canonical maps

\[
X \otimes (Y \otimes Z) \leftarrow \otimes^3 \{X, Y, Z\} \rightarrow (X \otimes Y) \otimes Z.
\]

These maps are equivalences if \( \mathcal{O} \) is a nonunital symmetric monoidal \( \infty \)-category, in general need not be.

**Remark 6.2.4.8.** Let \( \mathcal{O} \) be a corepresentable \( \infty \)-operad, and suppose we are given a map of finite sets \( \alpha : I \rightarrow J \). Let \( \{X_i\}_{i \in I} \) be a collection of objects of \( \mathcal{O} \). For \( j \in J \), set \( I_j = \alpha^{-1}\{j\} \subseteq I \), set \( Y_j = \otimes^I \{X_i\}_{i \in I_j} \), and set \( Z = \otimes^J \{Y_j\}_{j \in J} \). We have canonical operations

\[
\phi_j \in \text{Mul}_\mathcal{O}(\{X_i\}_{i \in I_j}, Y_j) \quad \psi \in \text{Mul}_\mathcal{O}(\{Y_j\}_{j \in J}, Z).
\]

Composing these, we obtain a point of \( \text{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Z) \), which is classified by a map \( \otimes^I \{X_i\}_{i \in I} \rightarrow Z \). This construction is functorial in each \( X_i \), and therefore defines a natural transformation of functors

\[
v_{\alpha} : \otimes^I \rightarrow \otimes^J \circ \prod_{j \in J} \otimes^{I_j}
\]

from \( \mathcal{O}^I \) to \( \mathcal{O} \). In particular, for objects \( X, Y, Z \in \mathcal{O} \), we have canonical maps

\[
\otimes^2(X, \otimes^2(Y, Z)) \leftarrow \otimes^3(X, Y, Z) \rightarrow \otimes^2(\otimes^2(X, Y), Z).
\]

**Example 6.2.4.9.** Every symmetric monoidal \( \infty \)-category is a corepresentable \( \infty \)-operad. Conversely, a corepresentable \( \infty \)-operad \( \mathcal{O} \) is a symmetric monoidal \( \infty \)-category if and only if, for every map of finite sets \( \alpha : I \rightarrow J \), the natural transformation

\[
v_{\alpha} : \otimes^I \rightarrow \otimes^J \circ \prod_{j \in J} \otimes^{I_j}
\]

of Remark 6.2.4.8 is an equivalence of functors from \( \mathcal{O}^I \) to \( \mathcal{O} \).
We now discuss the process of stabilizing a corepresentable \(\infty\)-operad.

**Definition 6.2.4.10.** Let \(p : O^\otimes \to N(Fin_\ast)\) be an \(\infty\)-operad. We will say that \(O^\otimes\) is stable if the following conditions are satisfied:

1. The \(\infty\)-operad \(O^\otimes\) is corepresentable (that is, \(p\) is a locally coCartesian fibration).
2. The underlying \(\infty\)-category \(O\) is stable.
3. For every finite set \(I\), the tensor product functor \(\otimes^I : O^I \to O\) is exact in each variable.

**Definition 6.2.4.11.** Let \(p : O^\otimes \to N(Fin_\ast)\) be an \(\infty\)-operad. We will say that \(O^\otimes\) is differentiable if the following conditions are satisfied:

1. The \(\infty\)-operad \(O^\otimes\) is corepresentable (that is, \(p\) is a locally coCartesian fibration).
2. The underlying \(\infty\)-category \(O\) is differentiable and admits finite colimits.
3. For every finite set \(I\), the tensor product functors \(\otimes^I : O^I \to O\) preserves sequential colimits.

**Definition 6.2.4.12.** Let \(p : O^\otimes \to N(Fin_\ast)\) be a differentiable \(\infty\)-operad. We will say that a map of \(\infty\)-operads \(q : \overline{O}^\otimes \to N(Fin_\ast)\) exhibits \(\overline{O}^\otimes\) as a stabilization of \(O^\otimes\) if the following conditions are satisfied:

1. The \(\infty\)-operad \(\overline{O}^\otimes\) is stable.
2. The underlying \(\infty\)-category \(\overline{O}\) is left exact.
3. For every finite set \(I\), the tensor product functor \(\otimes^I : O^I \to O\) factors (in an essentially unique way) as a composition \(\overline{O} \to \text{Sp}(\overline{O}) \to O\), where the functor \(e\) is exact.
4. The functor \(e : \overline{O} \to \text{Sp}(\overline{O})\) is an equivalence of \(\infty\)-categories; we let \(e^{-1}\) denote a homotopy inverse to \(e\).
5. For every finite set \(I\), let \(\otimes^I : O^I \to O\) and \(\overline{\otimes}^I : \overline{O}^I \to \overline{O}\) be defined as in Remark 6.2.4.4. Then \(q\) induces a natural transformation
   \[
   \otimes^I \circ (\Omega^\otimes_\ast)^I \to \Omega^\otimes_\ast \circ (e \circ \otimes^I \circ (e^{-1})^I)
   \]
   of functors from \(\text{Sp}(\overline{O})^I\) into \(O\) which exhibits \(e \circ \otimes^I \circ (e^{-1})^I\) as a derivative of the functor \(\otimes^I\).

**Example 6.2.4.13.** Let \(S^\times\) denote the Cartesian symmetric monoidal \(\infty\)-category whose underlying \(\infty\)-category is \(\ast\). Then \(S^\times\) is an initial object in the \(\infty\)-category of commutative algebra objects of \(\mathcal{P}_{L}\) (see Example 4.8.1.19). In particular, there is an essentially unique symmetric monoidal functor \(S^\times \to \text{Sp}\), where the underlying map of \(\infty\)-categories is given by the suspension spectrum functor \(\Sigma^\ast_\ast : \ast \to \text{Sp}\). The functor \(\Sigma^\ast_\ast\) is left adjoint to the functor \(\Omega^\infty : \text{Sp} \to \ast\). Applying Corollary 7.3.2.7, we see that \(\Omega^\infty\) underlies a map of \(\infty\)-operads \(q : \text{Sp}^\otimes \to S^\times\). Invoking the analysis of Example 6.2.3.28 and Variant 6.2.3.29, we deduce that \(q\) exhibits \(\text{Sp}^\otimes\) as the stabilization of the (differentiable) \(\infty\)-operad \(S^\times\).

The fundamental properties of Definition 6.2.4.12 are summarized in the following pair of results, which we will prove (in a more general form) in §6.2.5 and §6.2.6:

**Proposition 6.2.4.14.** Let \(C^\otimes\) be a differentiable \(\infty\)-operad. Then there exists a stable \(\infty\)-operad \(\overline{C}^\otimes\) and a map of \(\infty\)-operads \(q : \overline{C}^\otimes \to C^\otimes\) which exhibits \(\overline{C}^\otimes\) as a stabilization of \(C^\otimes\).

**Proposition 6.2.4.15.** Let \(q : \overline{C}^\otimes \to C^\otimes\) be a map of \(\infty\)-operads which exhibits the stable \(\infty\)-operad \(\overline{C}^\otimes\) as a stabilization of the differentiable \(\infty\)-operad \(C^\otimes\), and let \(O^\otimes\) be an arbitrary stable \(\infty\)-operad. Let \(\text{Alg}_{\otimes}^{ex}(C)\) denote the full subcategory of \(\text{Alg}_{\otimes}(C)\) spanned by those \(\infty\)-operad maps \(O^\otimes \to C^\otimes\) for which the underlying functor \(O \to C\) is left exact, and define \(\text{Alg}_{\otimes}^{ex}(C)\) similarly. Then composition with \(q\) induces an equivalence of \(\infty\)-categories \(\text{Alg}_{\otimes}^{ex}(\overline{C}) \to \text{Alg}_{\otimes}^{ex}(C)\).
Remark 6.2.4.16. It follows from Proposition 6.2.4.15 that the stabilization of a differentiable ∞-operad \( \mathcal{C}^\otimes \) is determined up to equivalence by \( \mathcal{C}^\otimes \).

Example 6.2.4.17. Let \( S_* \) denote the ∞-category of pointed spaces, which we regard as endowed with a symmetric monoidal structure via the smash product (see Remark 4.8.2.14). This symmetric monoidal structure is encoded by a coCartesian fibration \( S_*^\wedge \to N(\text{Fin}_*) \). The ∞-operad \( S_*^\wedge \) is differentiable, and therefore admits a stabilization \( q : \mathcal{C}^\otimes \to S_*^\wedge \) by Proposition 6.2.4.14. The underlying ∞-category \( \mathcal{C} \) of \( \mathcal{C}^\otimes \) can be identified with \( \text{Sp}(S_*) \simeq \text{Sp} \). It follows from the analysis of Example 6.2.3.28 that for every nonempty finite set \( I \), the associated tensor product functor \( \otimes^I : \mathcal{C}^\otimes \to \mathcal{C} \) is given by the iterated smash product of spectra. However, when \( I = \emptyset \) the tensor product functor \( \otimes^\emptyset : \Delta^0 \simeq \mathcal{C}^I \to \mathcal{C} \) is given by a zero object of \( \mathcal{C} \) (rather than the sphere spectrum). In particular, we see that \( \mathcal{C}^\otimes \) is a unital corepresentable ∞-operad (Remark 6.2.4.6), which is not a symmetric monoidal ∞-category. Informally speaking, the corepresentable ∞-operad \( \mathcal{C}^\otimes \) can be obtained from \( \text{Sp}^\otimes \) by “killing the unit object”.

Using Example 6.2.3.28, we also see that \( \mathcal{C}^\otimes \) can be identified with the stabilization of the differentiable ∞-operad \( S_*^\wedge \); the identification is induced by composing the map \( q : \mathcal{C}^\otimes \to S_*^\wedge \) with a map of ∞-operads \( S_*^\wedge \to S_*^\wedge \).

6.2.5 Stabilization of ∞-Operads

Let \( \mathcal{C}^\otimes \) be a differentiable ∞-operad (see Definition 6.2.4.11). In §6.2.4, we introduced the notion of a stabilization of \( \mathcal{C}^\otimes \). Our goal in this section is to prove Proposition 6.2.4.14, which asserts that \( \mathcal{C}^\otimes \) admits a stabilization. The proof will proceed by means of an explicit construction, which is closely related to the stabilization construction given in §6.2.2. However, the present case is considerably more complicated, because we must consider functors of several variables. For later use, it will be convenient to introduce one other complication: we will treat not only the case of a single differentiable ∞-operad, but a family of differentiable ∞-operads.

Definition 6.2.5.1. Let \( p : \mathcal{O}^\otimes \to S \times N(\text{Fin}_*) \) be a map of simplicial sets. We will say that \( p \) is a local S-family of ∞-operads if, for every \( n \)-simplex of \( S \), the induced map \( \Delta^n \times S \mathcal{O}^\otimes \to \Delta^n \times N(\text{Fin}_*) \) is a \( \Delta^n \)-family of ∞-operads, in the sense of Definition 2.3.2.10. We will say that \( p \) is a corepresentable local S-family of ∞-operads if \( p \) is a local S-family of ∞-operads, and the map \( p \) is a locally coCartesian fibration.

Warning 6.2.5.2. Let \( S \) be an ∞-category. If \( p : \mathcal{O}^\otimes \to S \times N(\text{Fin}_*) \) is an S-family of ∞-operads (in the sense of Definition 2.3.2.10), then \( p \) is a local S-family of ∞-operads. The converse is generally not true: Definition 6.2.5.1 does not require that \( p \) be a categorical fibration of simplicial sets. However, if every equivalence in \( S \) is a degenerate edge (for example, if \( S \) is the nerve of a partially ordered set), then every local S-family of ∞-operads is an S-family of ∞-operads. This follows from the characterization of categorical fibrations supplied by Corollary T.2.4.6.5.

Remark 6.2.5.3. Let \( p : \mathcal{O}^\otimes \to S \times N(\text{Fin}_*) \) be a local S-family of ∞-operads. We will generally abuse terminology by referring to \( \mathcal{O}^\otimes \) as a local S-family of ∞-operads, if the map \( p \) is clear in context. For each vertex \( s \in S \), we let \( \mathcal{O}_s^\otimes \) denote the ∞-operad given by the fiber product \( \mathcal{O}^\otimes \times_S \{s\} \), and \( \mathcal{O}_s \) its underlying ∞-category.

Remark 6.2.5.4. Let \( q : \mathcal{O}^\otimes \to S \times N(\text{Fin}_*) \) be a corepresentable local S-family of ∞-operads, and let \( e : X \to Y \) be an edge of \( \mathcal{O}^\otimes \) lying over an edge \( e_0 : s \to t \) in \( S \). The following conditions are equivalent:

1. The edge \( e \) is locally \( q \)-coCartesian.
2. For every inert morphism \( e' : Y \to Z \) in \( \mathcal{O}_t^\otimes \) and every 2-simplex

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Z
\end{array}
\]

\[
\begin{array}{ccc}
Y & \xrightarrow{e'} & Z
\end{array}
\]

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Z
\end{array}
\]
Let \( p \) be a simplicial set equipped with a map \( \chi : S \to N(\text{Fin}_*) \), and let \( p : \mathcal{C} \to S \) be a locally coCartesian fibration. For each vertex \( s \in S \), let \( \mathcal{C}_s \) denote the fiber of \( p \) over \( s \). A \( \chi \)-decomposition of \( \mathcal{C} \) consists of an \( I^* \)-decomposition \( \{ W(i)^* \}_{i \in I^*} \) of each fiber \( \mathcal{C}_s \), satisfying the following condition:

\( \text{(*)} \) There exists an equivalence of \( \infty \)-categories \( \mathcal{C} \to \prod_{i \in I^*} \mathcal{C}(i) \), where each \( \mathcal{C}(i) \) is a weakly contractible \( \infty \)-category, such that for each \( j \neq i \), we can identify \( \mathcal{C}(j) \) with the \( \infty \)-category \( \mathcal{C}[W(i)^{-1}] \) obtained from \( \mathcal{C} \) by formally inverting the morphisms belonging to \( W(i) \).
Let \( e : s \to t \) be an edge of the simplicial set \( S \), so that \( e \) induces a functor \( e_t : s_\ast \to t_\ast \) be the induced functor and a map of pointed finite sets \( \alpha : I_s^\ast \to I_t^\ast \). Then for each \( j \in I_t \), the functor \( e_t \) carries \( \bigcap_{i \in \alpha^{-1}(j)} W(i)_s^\ast \) into \( W(j)_t^\ast \).

**Remark 6.2.5.9.** Let \( \chi : S \to N(\mathcal{F}_{\text{fin}}) \) be a map of simplicial sets and let \( p : \mathcal{C} \to S \) be a locally coCartesian fibration equipped with a \( \chi \)-decomposition. For every vertex \( s \in S \), the fiber \( \mathcal{C}_s \) is equivalent to a product \( \prod_{i \in I_s^\ast} \mathcal{C}_s(i) \), where \( \chi(s) = I_s^\ast \). Moreover, every edge \( e : s \to t \) determines a map of pointed finite sets \( \alpha : I_s^\ast \to I_t^\ast \) and a functor \( e_t : \prod_{i \in I_s^\ast} \mathcal{C}_s(i) \to \prod_{j \in I_t^\ast} \mathcal{C}_t(j) \), which factors as a composition

\[
\prod_{i \in I_s^\ast} \mathcal{C}_s(i) \to \prod_{i \in \alpha^{-1} I_t^\ast} \mathcal{C}_s(i) \xrightarrow{\prod_{j \in I_t^\ast} F_j} \prod_{j \in I_t^\ast} \mathcal{C}_t(j),
\]

for some functors \( F_j : \prod_{i \in \alpha^{-1}(j)} \mathcal{C}_s(i) \to \mathcal{C}_t(j) \). Moreover, the functors \( F_j \) are uniquely determined up to equivalence.

**Example 6.2.5.10.** Let \( p : O^\otimes \to S \times N(\mathcal{F}_{\text{fin}}) \) be a corepresentable local \( S \)-family of \( \infty \)-operads, so that \( p \) induces a locally coCartesian fibration \( q : O^\otimes \to S \times N(\mathcal{F}_{\text{fin}}) \). Let \( \chi : S \times N(\mathcal{F}_{\text{fin}}) \to N(\mathcal{F}_{\text{fin}}) \) be the projection onto the second factor. Assume that, for each vertex \( s \in S \), the \( \infty \)-category \( O_s \) is weakly contractible. Then there is a canonical \( \chi \)-decomposition on the locally coCartesian fibration \( q \). For each vertex \( (n), s \in N(\mathcal{F}_{\text{fin}}) \times S \), we have a \( (n)^\ast \)-decomposition \( \{W(i)\}_{1 \leq i \leq n} \) of the fiber \( O^\otimes_{(n), s} \), where \( W(i) \) is the collection of morphisms \( \alpha \) in \( O^\otimes_{(n), s} \) such that \( \phi(\alpha) \) is an equivalence, where \( \phi : O^\otimes_{(n), s} \to O_s \) is the functor associated to the inert morphism \( p^\ast : (n) \to (1) \) in the category \( \mathcal{F}_{\text{fin}} \).

**Notation 6.2.5.11.** Let \( \chi : S \to N(\mathcal{F}_{\text{fin}}) \) be a map of simplicial sets, which assigns to each vertex \( s \in S \) a pointed finite set \( I_s^\ast \). Suppose we are given locally coCartesian fibrations \( p : \mathcal{C} \to S \) and \( q : \mathcal{D} \to S \) equipped with \( \chi \)-decompositions \( \{W(i)_{\mathcal{C}}\}_{s \in S, i \in I_s^\ast} \) and \( \{W(i)_{\mathcal{D}}\}_{s \in S, i \in I_s^\ast} \). We will say that a functor \( U \in \text{Fun}_S(\mathcal{C}, \mathcal{D}) \) is decomposition-compatible if, for every vertex \( s \in S \), the induced functor \( U_s : \mathcal{C}_s \to \mathcal{D}_s \) carries \( W(i)_s^\ast \) into \( W(i)_s^\ast \), for each \( i \in I_s^\ast \). We let \( \text{Fun}_\chi(\mathcal{C}, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}_S(\mathcal{C}, \mathcal{D}) \) spanned by those functors which are decomposition-compatible.

**Remark 6.2.5.12.** Let \( \chi : S \to N(\mathcal{F}_{\text{fin}}) \), \( p : \mathcal{C} \to S \) and \( q : \mathcal{D} \to S \) be as in Notation 6.2.5.11, so that the \( \chi \)-decompositions of \( \mathcal{C} \) and \( \mathcal{D} \) determine equivalences

\[
\mathcal{C}_s \simeq \prod_{i \in I_s^\ast} \mathcal{C}_s(i) \quad \mathcal{D}_s \simeq \prod_{i \in I_s^\ast} \mathcal{D}_s(i)
\]

for each vertex \( s \in S \). If \( U \in \text{Fun}_S(\mathcal{C}, \mathcal{D}) \) is decomposition-compatible, then the induced functor \( U_s : \mathcal{C}_s \to \mathcal{D}_s \) can be identified with a product of functors \( \{U_s(i) : \mathcal{C}_s(i) \to \mathcal{D}_s(i)\}_{i \in I_s^\ast} \) for \( s \in S \).

Let \( e : s \to t \) be an edge of \( S \) inducing a map of pointed finite sets \( \alpha : I_s^\ast \to I_t^\ast \), so that the induced maps \( \mathcal{C}_s \to \mathcal{C}_t \) and \( \mathcal{D}_s \to \mathcal{D}_t \) determine functors

\[
F_j : \prod_{i \in \alpha^{-1}(j)} \mathcal{C}_s(i) \to \mathcal{C}_t(j) \quad G_j : \prod_{i \in \alpha^{-1}(j)} \mathcal{D}_s(i) \to \mathcal{D}_t(j)
\]

for \( j \in I_t^\ast \). For each \( j \in I_t^\ast \), \( U \) determines a natural transformation

\[
\beta_j : G_j \circ \prod_{i \in \alpha^{-1}(j)} U_s(i) \to U_t(j) \circ F_j
\]

of functors from \( \prod_{i \in \alpha^{-1}(j)} \mathcal{C}_s(i) \) to \( \mathcal{D}_t(j) \).

**Definition 6.2.5.13.** Let \( \chi : S \to N(\mathcal{F}_{\text{fin}}) \) be a map of simplicial sets. Suppose we are given locally coCartesian fibrations \( q : \mathcal{C} \to S \) and \( p : \mathcal{C} \to S \) equipped with \( \chi \)-decompositions, and that each fiber \( \mathcal{C}_s = \mathcal{C} \times S \{s\} \) is an \( \infty \)-category which admits finite limits. We will say that a functor \( U \in \text{Fun}_S(\mathcal{C}, \mathcal{C}) \) exhibits \( \mathcal{C} \) as a stabilization of \( p \) if the following conditions are satisfied:
(a) The functor $U$ is decomposition-compatible (Notation 6.2.5.11).

(b) For each $s \in S$, write $\chi(s) = I_s^*$ for some finite set $I_s^*$, so that the $\chi$-decompositions of $p$ and $q$ determine equivalences

$$C_s \simeq \prod_{i \in I_s^*} C_s(i) \quad \prod_{i \in I_s^*} C_s(i),$$

and $U$ induces functors $U_s(i) : \overline{C}_s(i) \to C_s(i)$. Then each $U_s(i)$ factors as a composition $\overline{C}_s(i) \xrightarrow{V_s(i)} \operatorname{Sp}(C_s(i)) \xrightarrow{\varphi_s(i)} C_s(i)$. In particular, each $\overline{C}_s(i)$ is a stable $\infty$-category, and each of the functors $U_s(i)$ is left exact.

(c) Let $s : t \to b$ be an edge of $S$, inducing a map of pointed finite sets $\alpha : I_s^* \to I_t^*$. Then $e$ induces functors

$$F_j : \prod_{i \in \alpha^{-1}(j)} C_s(i) \to C_s(t(j)), \quad f_j : \prod_{i \in \alpha^{-1}(j)} C_s(i) \to \overline{C}_s(j),$$

and $U$ determines natural transformations

$$\beta_j : F_j \circ \prod_{i \in \alpha^{-1}(j)} U_s(i) \to U_t(j) \circ f_j$$

for $j \in I^*$. Then $\beta_j$ exhibits the functors $V_t(j)^{-1} \circ f_j \circ \prod_{i \in \alpha^{-1}(j)} V_s(i)$ as derivatives of the functors $F_j$.

**Remark 6.2.5.14.** In the situation of Definition 6.2.5.13, suppose that $\chi : S \to \operatorname{N}(\text{Fin}_*)$ is the constant functor taking the value $\{1\}$ and that $p : \overline{C} \to S$ is a locally differentiable fibration. Then a map $U : \overline{C} \to C$ exhibits $\overline{C}$ as a stabilization of $p$ in the sense of Definition 6.2.5.13 if and only if it exhibits $\overline{C}$ as a stabilization of $p$ in the sense of Definition 6.2.5.14.

**Warning 6.2.5.15.** Let $S$ be a simplicial set equipped with a map $\chi : S \to \operatorname{N}(\text{Fin}_*)$, let $p : \overline{C} \to S$ be a locally differentiable fibration equipped with a $\chi$-decomposition, and suppose that each fiber $\overline{C}_s$ admits finite colimits. Let $U : \overline{C} \to C$ be a map which exhibits $\overline{C}$ as stabilization of $p$, and let $\overline{p} = p \circ U$. If $p$ is a coCartesian fibration, it generally does not follow that $\overline{p}$ is a coCartesian fibration. To understand the issue, let us suppose for simplicity that $S = \Delta^2$, so that $\chi$ classifies a pair of maps $I_\alpha \xrightarrow{\alpha} J_\alpha \xrightarrow{\beta} K_\alpha$ between pointed finite sets. Let us denote the fibers of $p$ by $C_0, C_1,$ and $C_2$. Then the $\chi$-decomposition of $\overline{C}$ determines equivalences

$$C_0 \simeq \prod_{i \in I} C(i) \quad C_1 \simeq \prod_{j \in J} C(j) \quad C_2 \simeq \prod_{k \in K} C(k),$$

together with functors

$$\{F(j) : \prod_{\alpha(i) = j} C(i) \to C(j)\}_{j \in J} \quad \{G(k) : \prod_{\beta(j) = k} C(j) \to C(k)\}_{k \in K} \quad \{H(k) : \prod_{(\beta \circ \alpha)(i) = k} C(i) \to C(k)\}_{k \in K}$$

and natural transformations $\{\phi_k : H(k) \to G(k) \circ \prod_{\beta(j) = k} F(j)\}_{k \in K}$. The map $p$ is a coCartesian fibration if and only if each of the natural transformations $\phi_k$ is an equivalence. However, the map $\overline{p}$ is a coCartesian fibration if and only if each of the composite maps

$$\overline{\partial}H(k) \to \overline{\partial}G(k) \circ \prod_{\beta(j) = k} F(j) \xrightarrow{\overline{\partial}G(k)} \overline{\partial}G(k) \circ \prod_{\beta(j) = k} \overline{\partial}F(j).$$

Consequently, if $p$ is a coCartesian fibration, then $\overline{p}$ is a coCartesian fibration if and only if each of the natural transformations $\iota_k$ is an equivalence. This is automatic in the following situations:

(a) The map $\alpha$ is inert, and each of the maps $F(j)$ is an equivalence.
6.2. DIFFERENTIATION

(b) The map $\beta$ is inert, and each of the maps $G(k)$ is an equivalence.

c) The maps $\alpha$ and $\beta$ are surjective, and the functors $F(j)$ and $G(k)$ are reduced in each variable (see Theorem 6.2.1.22).

Proposition 6.2.4.14 is an immediate consequence of the following pair of assertions:

**Proposition 6.2.5.16.** Let $\chi : S \to N(\text{Fin}_*)$ be a map of simplicial sets which carries each vertex $s \in S$ to a finite pointed set $I_s^\alpha$. Let $p : C \to S$ be a differentiable fibration equipped with a $\chi$-decomposition, and suppose that each fiber $C_s$ admits finite limits. Then there exists a locally coCartesian fibration $\overline{C} \to S$ equipped with a $\chi$-decomposition, and a map $U \in \text{Fun}_S(\overline{C}, C)$ which exhibits $\overline{C}$ as a stabilization of $C$.

**Proposition 6.2.5.17.** Let $p : O^\otimes \to S \times N(\text{Fin}_*)$ be a differentiable $S$-family of $\infty$-operads. Let $\chi : S \times N(\text{Fin}_*) \to N(\text{Fin}_*)$ be the projection onto the second factor, and regard $O^\otimes$ as endowed with the $\chi$-decomposition of Example 6.2.5.10. Suppose that $U : O^\otimes \to O^\otimes$ exhibits $O^\otimes$ as a stabilization of $O^\otimes$, in the sense of Definition 6.2.5.13. Then the underlying map $\overline{O} \to S \times N(\text{Fin}_*)$ is a stable local $S$-family of $\infty$-operads.

We begin with the proof of Proposition 6.2.5.17, which is rather formal. We need the following general recognition principle:

**Lemma 6.2.5.18.** Let $q : O^\otimes \to S \times N(\text{Fin}_*)$ be a locally coCartesian fibration. Then $q$ is a corepresentable local $S$-family of $\infty$-operads if and only if the following conditions are satisfied:

1. Let $e : (s, \langle m \rangle) \to (t, \langle n \rangle)$ be an edge of $S \times N(\text{Fin}_*)$, suppose we are given an inert morphism $\alpha : \langle m' \rangle \to \langle m \rangle$, and let $\sigma : \Delta^2 \to S \times N(\text{Fin}_*)$ be the 2-simplex corresponding to the diagram

$$
\begin{array}{ccc}
(s, \langle m \rangle) & \xrightarrow{(id, \alpha)} & (s, \langle m' \rangle) \\
\downarrow e & & \downarrow \sigma \\
(t, \langle n \rangle) & & (t, \langle n \rangle)
\end{array}
$$

Then the projection map $\Delta^2 \times_{S \times N(\text{Fin}_*)} O^\otimes \to \Delta^2$ is a coCartesian fibration.

2. Let $e : (s, \langle m \rangle) \to (t, \langle n \rangle)$ be an edge of $S \times N(\text{Fin}_*)$, let $\beta : \langle n \rangle \to \langle n' \rangle$ be an inert morphism, and let $\sigma : \Delta^2 \to S \times N(\text{Fin}_*)$ be the 2-simplex corresponding to the diagram

$$
\begin{array}{ccc}
(t, \langle n \rangle) & \xleftarrow{\beta} & (t, \langle n' \rangle) \\
\downarrow e & & \downarrow \sigma \\
(s, \langle m \rangle) & & (s, \langle m \rangle)
\end{array}
$$

Then the projection map $\Delta^2 \times_{S \times N(\text{Fin}_*)} O^\otimes \to \Delta^2$ is a coCartesian fibration.

3. For each vertex $s \in S$ and each $n \geq 0$, the collection of inert maps $\rho^s : \langle n \rangle \to \langle 1 \rangle$ induce functors $O^\otimes_{(s, \langle n \rangle)} \to O^\otimes_{(s, \langle 1 \rangle)}$ which determine an equivalence $O^\otimes_{(s, \langle n \rangle)} \simeq (O^\otimes_{(s, \langle 1 \rangle)})^n$.

**Proof.** We may assume without loss of generality that $S = \Delta^k$ for some integer $k$. Using Lemma T.2.4.2.7, we can reformulate (1) as follows:

1'. For each vertex $s \in S$ and each locally $q$-coCartesian $f$ in $O^\otimes_s$ whose image in $N(\text{Fin}_*)$ is inert, $f$ is $q$-coCartesian.

Suppose that (3) is satisfied. We will show that (2) can be formulated as follows:
(2') Let \( t \) be a vertex of \( S \), let \( C \in \mathcal{O}_s^\otimes \) be an object, and suppose we are given a pair of locally \( q \)-coCartesian morphisms \( C \to C' \) and \( C \to C'' \) in \( \mathcal{O}_s^\otimes \) covering invert morphisms \( \beta : \langle n \rangle \to \langle n' \rangle \) and \( \gamma : \langle n \rangle \to \langle n'' \rangle \) which induce a bijection \( (n')^\circ \coprod (n'')^\circ \to (n)^\circ \). Then \( C \) is a \( q \)-product of \( C' \) with \( C'' \).

Note that \( \mathcal{O}^\otimes \) is an \( S \)-family of \( \infty \)-operads if and only if it satisfies conditions (a), (b), and (c) of Definition 2.3.2.10. The desired result follows from the implications (a) \( \Leftrightarrow (1') \), (b) \( \Leftrightarrow (2') \), and (a) + (b) + (c) \( \Rightarrow (3) \) \( \Rightarrow (c) \).

Assume now that (3) is satisfied; we will show that (2) \( \Leftrightarrow (2') \). Fix a morphism \( e : (s, \langle m \rangle) \to (t, \langle n \rangle) \) and an invert morphism \( \beta : \langle n \rangle \to \langle n' \rangle \), and choose another invert morphism \( \gamma : \langle n \rangle \to \langle n'' \rangle \) such that \( \gamma^{-1}(n'')^\circ \) is the complement of \( \beta^{-1}(n')^\circ \) in \( \langle n \rangle^\circ \). Let \( e' : (s, \langle m \rangle) \to (t, \langle n' \rangle) \) and \( e'' : (s, \langle m \rangle) \to (t, \langle n'' \rangle) \) be the compositions of \( e \) with \( \beta \) and \( \gamma \), respectively. Consider the induced functors

\[
e_1 : \mathcal{O}^\otimes_{(s, \langle m \rangle)} \to \mathcal{O}^\otimes_{(t, \langle n \rangle)} \quad e'_1 : \mathcal{O}^\otimes_{(s, \langle m \rangle)} \to \mathcal{O}^\otimes_{(t, \langle n' \rangle)} \quad e''_1 : \mathcal{O}^\otimes_{(s, \langle m \rangle)} \to \mathcal{O}^\otimes_{(t, \langle n'' \rangle)}
\]

\[
\beta_1 : \mathcal{O}^\otimes_{(t, \langle n \rangle)} \to \mathcal{O}^\otimes_{(t, \langle n' \rangle)} \quad \gamma_1 : \mathcal{O}^\otimes_{(t, \langle n \rangle)} \to \mathcal{O}^\otimes_{(t, \langle n'' \rangle)},
\]

so that we have natural transformations

\[
e'_1 \to \beta_1 \circ e_1 \quad e''_1 \to \gamma_1 \circ e_1.
\]

Condition (2) asserts that these natural transformations are equivalences. In other words, condition (2) is equivalent to the requirement that the induced map \( e'_1 \times e''_1 \to (\beta_1 \times \gamma_1) \circ e_1 \) is an equivalence of functors from \( \mathcal{O}^\otimes_{(s, \langle m \rangle)} \) to \( \mathcal{O}^\otimes_{(t, \langle n' \rangle)} \times \mathcal{O}^\otimes_{(t, \langle n'' \rangle)} \). Condition (3) guarantees that \( \beta_1 \times \gamma_1 \) is an equivalence of \( \infty \)-categories. Consequently, we can reformulate condition (2) as follows: for every pair \((e, \beta)\) as above, for every object \( X \in \mathcal{O}^\otimes_{(s, \langle m \rangle)} \) and for every object \( Y \in \mathcal{O}^\otimes_{(t, \langle n \rangle)} \), the canonical map

\[
\text{Map}_{\mathcal{O}^\otimes_{(s, \langle m \rangle)}}(e_1 X, Y) \to \text{Map}_{\mathcal{O}^\otimes_{(t, \langle n \rangle)}}(e'_1 X, \beta Y) \times \text{Map}_{\mathcal{O}^\otimes_{(t, \langle n' \rangle)}}(e''_1 X, \gamma Y)
\]

is a homotopy equivalence. If we regard \( Y \) and \( \beta \) as fixed, then this condition is satisfied for all pairs \((e, X)\) if and only if the canonical maps \( \beta_1 Y \to Y \to \gamma_1 Y \) exhibit \( Y \) as a \( q \)-product of \( \beta_1 Y \) with \( \gamma_1 Y \). It follows that (2) \( \Leftrightarrow (2') \), as desired.

Proof of Proposition 6.2.5.17. Let \( p : \mathcal{O}^\otimes \to S \times \mathcal{N}(\mathcal{F}_{\text{fin}}) \) be a differentiable local \( S \)-family of \( \infty \)-operads, and let \( \overline{\mathcal{O}}^\otimes \) be a stabilization of \( p \) (in the sense of Definition 6.2.5.13). We will show that \( \overline{\mathcal{O}}^\otimes \) is a corepresentable local \( S \)-family of \( \infty \)-operads (the stability of \( \overline{\mathcal{O}}^\otimes \to S \times \mathcal{N}(\mathcal{F}_{\text{fin}}) \) will then follow immediately from the definition of a stabilization). For this, it will suffice to show that the underlying locally coCartesian fibration \( q : \mathcal{O}^\otimes \to S \times \mathcal{N}(\mathcal{F}_{\text{fin}}) \) satisfies hypotheses (1), (2) and (3) of Lemma 6.2.5.18. Condition (3) follows immediately from Definition 6.2.5.13, and conditions (1) and (2) follow from the discussion in Warning 6.2.5.15.

We devote the remainder of this section to an explicit construction of the stabilizations whose existence is asserted by Proposition 6.2.5.16.

Notation 6.2.5.19. The \( \infty \)-category \( \mathcal{S}_{\text{fin}}^\otimes \) of pointed finite spaces admits a symmetric monoidal structure given by the smash product of pointed spaces (see Notation 6.2.1.10), encoded by a coCartesian fibration \( p : (\mathcal{S}_{\text{fin}}^\otimes)^\wedge \to \mathcal{N}(\mathcal{F}_{\text{fin}}) \). The coCartesian fibration \( p \) is equipped with a \( \chi \)-decomposition, where \( \chi \) denotes the identity map from \( \mathcal{N}(\mathcal{F}_{\text{fin}}) \) to itself (see Example 6.2.5.10).

Construction 6.2.5.20. Let \( \chi : S \to \mathcal{N}(\mathcal{F}_{\text{fin}}) \) be a map of simplicial sets which carries each vertex \( s \in S \) to a finite pointed set \( I^r_s \). Let \( p : \mathcal{C} \to S \) be a locally coCartesian fibration equipped with a \( \chi \)-decomposition \( \{W(i)^s\}_{s \in S, i \in I^r_s} \), and assume that each of the \( \infty \)-categories \( \mathcal{C}_{\text{fin}} \) admits finite limits.

We define a simplicial set \( \text{PStab}_\chi(p) \) equipped with a map \( \text{PStab}_\chi(p) \to S \) so that the following universal property is satisfied: for every map of simplicial sets \( K \to S \), we have a bijection

\[
\text{Fun}_S(K, \text{PStab}_\chi(p)) = \text{Fun}_S(K \times_N \mathcal{F}_{\text{fin}}, (\mathcal{S}_{\text{fin}}^\otimes)^\wedge, \mathcal{C}).
\]
For each vertex $s \in S$, we can identify the fiber $\text{PStab}_\chi(p)_s$ with the $\infty$-category $\text{Fun}(\mathcal{S}_{s}^\text{fin}, \mathcal{C}_s)$. If we are given an object of $\text{PStab}_\chi(p)_s$ corresponding to a decomposition-compatible functor $F : (\mathcal{S}_{s}^\text{fin})^\wedge \rightarrow \mathcal{C}_s$, then $F$ factors as a composition

$$(\mathcal{S}_{s}^\text{fin})^\wedge \rightarrow \prod_{i \in I^s} \mathcal{S}_{s}^\text{fin} F_i \rightarrow \prod_{i \in I^s} \mathcal{C}_s(i) \simeq \mathcal{C}_s$$

for some functors $F_i : \mathcal{S}_{s}^\text{fin} \rightarrow \mathcal{C}_s(i)$ (here the $\infty$-categories $\mathcal{C}_s(i)$ are defined as in Remark 6.2.5.9). We let $\text{Stab}_\chi(p)$ denote the full simplicial subset of $\text{PStab}_\chi(p)$ spanned by those vertices which correspond to decomposition-compatible functors $F$ for which each of the functors $F(i)$ is reduced and excisive.

Note that the unit $S^0 \in \mathcal{S}_{s}^\text{fin}$ has the structure of a commutative algebra object of $\mathcal{S}_{s}^\text{fin}$, and therefore determines a section of the coCartesian fibration $(\mathcal{S}_{s}^\text{fin})^\wedge \rightarrow \text{N}(\text{Fin}_s^\text{fin})$. Composition with this section determines an evaluation map $\text{PStab}_\chi(p) \rightarrow \mathcal{C}$, which restricts to a map $\Omega^\infty_\chi : \text{Stab}_\chi(p) \rightarrow \mathcal{C}$.

**Remark 6.2.5.21.** In the special case where $\chi : S \rightarrow \text{N}(\text{Fin}_s^\text{fin})$ is the constant functor taking the value $(1)$, Construction 6.2.5.20 reduces to Construction 6.2.2.2.

Let $\mathcal{C} \xrightarrow{\mathcal{E}} S \xrightarrow{\chi} \text{N}(\text{Fin}_s^\text{fin})$ be as in Construction 6.2.5.20. Our next goal is to prove that, under some mild assumptions, the map $\Omega^\infty_\chi : \text{Stab}_\chi(p) \rightarrow \mathcal{C}$ exhibits $\text{Stab}_\chi(p)$ as a stabilization of $\mathcal{C}$. Here we will depart slightly from the exposition of §6.2.2: for the applications in §6.3, we need to treat the case of locally differentiable fibrations which are not reduced. In this case, the existence of the requisite derivatives requires some additional assumptions.

**Remark 6.2.5.22.** Let $\{\mathcal{C}_i\}_{i \in I}$ be a finite collection of weakly contractible $\infty$-categories. Then the product $\prod_{i \in I} \mathcal{C}_i$ is differentiable, pointed, or admits finite colimits if and only if each of the $\infty$-categories $\mathcal{C}_i$ has the same property. Consequently, if $\chi : S \rightarrow \text{Fin}_s^\text{fin}$ is a map of simplicial sets and $p : \mathcal{C} \rightarrow S$ is a locally coCartesian fibration equipped with a $\chi$-decomposition, then $p$ is a locally differentiable fibration if and only if the following conditions are satisfied:

(a) For each vertex $s \in S$, let $\chi(s) = I_s^s$ so that the $\chi$-decomposition of $p$ determines an equivalence $\mathcal{C}_s \simeq \prod_{i \in I^s} \mathcal{C}_s(i)$. Then each $\mathcal{C}_s(i)$ is a differentiable $\infty$-category.

(b) Let $s \rightarrow t$ be an edge of $S$ inducing a map of pointed finite sets $\alpha : I^s \rightarrow I^t$. Then, for each $j \in I^t$, the induced functor

$$\prod_{i \in \alpha^{-1}(j)} \mathcal{C}_s(i) \rightarrow \mathcal{C}_t(j)$$

preserves sequential colimits separately in each variable.

**Example 6.2.5.23.** Let $S = \Delta^0$ and let $\chi : S \rightarrow \text{N}(\text{Fin}_s^\text{fin})$ be the map given by an object $I_s \in \text{Fin}_s^\text{fin}$, where $I$ is some finite set. Any $\infty$-category $\mathcal{C}$ admits a unique locally coCartesian fibration $p : \mathcal{C} \rightarrow S$, and giving a $\chi$-decomposition of $\mathcal{C}$ is equivalent to giving an $I$-decomposition of $\mathcal{C}$ in the sense of Definition 6.2.5.6. Such a decomposition determines an equivalence $\mathcal{C} \simeq \prod_{i \in I} \mathcal{C}(i)$. If $\mathcal{C}$ admits finite limits, we have a canonical equivalence of $\infty$-categories $\text{Stab}_\chi(p) \simeq \prod_{i \in I} \text{Sp}(\mathcal{C}(i)) \simeq \text{Sp}(\mathcal{C})$.

**Remark 6.2.5.24.** Let $\chi : S \rightarrow \text{N}(\text{Fin}_s^\text{fin})$ be a map of simplicial sets, and let $p : \mathcal{C} \rightarrow S$ be a locally coCartesian fibration equipped with a $\chi$-decomposition. For every map of simplicial sets $\phi : T \rightarrow S$, let $p_T : \mathcal{C} \times_S T \rightarrow T$ be the induced locally coCartesian fibration, and observe that $\mathcal{C} \times_S T$ inherits a $(\chi \circ \phi)$-decomposition. Unwinding the definitions, we obtain a canonical isomorphism of simplicial sets $\text{Stab}_{\chi \circ \phi}(p_T) \simeq \text{Stab}_\chi(p) \times_s T$.

Proposition 6.2.5.16 is an immediate consequence of the following more precise assertion:

**Theorem 6.2.5.25.** Let $\chi : S \rightarrow \text{N}(\text{Fin}_s^\text{fin})$ be a map of simplicial sets which carries each vertex $s \in S$ to a finite pointed set $I_s^s$. Let $p : \mathcal{C} \rightarrow S$ be a differentiable fibration equipped with a $\chi$-decomposition $\{W(i)^s\}_{s \in S, i \in I^s}$. Assume that, for each $s \in S$, the $\infty$-category $\mathcal{C}_s$ admits finite colimits. Then:
(1) The induced map \( q : \text{Stab}_\chi(p) \to S \) is a locally coCartesian fibration.

(2) For each \( s \in S \) and \( i \in I^s \), let \( W_s(i) \) be the collection of those morphisms \( \alpha : F \to F' \) in \( \text{Stab}_\chi(p)_s \) such that, for each object \( X \in (S_s^\infty)_{I^s} \), the induced map \( F(X) \to F'(X) \) belongs to \( W(i)^s \). Then the collection \( \{W_s(i)\}_{s \in S, i \in I^s} \) determines a \( \chi \)-decomposition of \( \text{Stab}_\chi(p) \).

(3) Let \( \Omega_\chi^\infty : \text{Stab}_\chi(p) \to \mathcal{C} \) be as in Construction 6.2.20. Then \( \Omega_\chi^\infty \) exhibits \( \text{Stab}_\chi(p) \) as a stabilization of \( p \), in the sense of Definition 6.2.15.

**Proof.** We first prove that the map \( \text{Stab}_\chi(p) \to S \) is an inner fibration. Using Remark 6.2.24, we can reduce to the case where \( S \) is a simplex. In this case, Theorem T.2.4.6.1 implies that \( p \) is a categorical fibration. The projection map \((s^\infty)^e \to N(F\text{Fin}_*)\) is a coCartesian fibration and therefore a flat categorical fibration (Example B.3.11). Using Proposition B.4.5, we deduce that \( \text{PStab}_\chi \to S \) is a categorical fibration, and in particular an inner fibration. Since \( \text{Stab}_\chi(q) \) is a full simplicial subset of \( \text{PStab}_\chi(p) \), we conclude that \( \text{Stab}_\chi(p) \to S \) is also an inner fibration.

We now complete the proof of (1) by showing that \( q : \text{Stab}_\chi(p) \to S \) is a locally coCartesian fibration. Fix an edge \( e : s \to t \) in the simplicial set \( S \) and an object \( F \in \text{Stab}_\chi(p)_s \). We wish to show that there exists an object \( G \in \text{Stab}_\chi(p)_t \) and a locally \( q \)-coCartesian edge \( \sigma : F \to G \) lifting \( e \). Replacing \( F \) by the fiber product \( \Delta^1 \times_S F \), we may reduce to the case where \( S = \Delta^1 \). Evaluating \( \chi \) on the edge \( e \), we obtain a map of pointed finite sets \( \alpha : I^s \to I^t \). The \( \chi \)-decomposition of \( F \) determines equivalences

\[
\mathcal{C}_s \simeq \prod_{i \in I^s} \mathcal{C}_s(i) \quad \mathcal{C}_t \simeq \prod_{j \in I^t} \mathcal{C}_t(j).
\]

Moreover, the edge \( e \) determines a functor \( e_f : \mathcal{C}_s \to \mathcal{C}_t \), which is given as a product of functors \( \{e_f(i) : \prod_{\alpha(i)=j} \mathcal{C}_s(i) \to \mathcal{C}_t(j)\}_{j \in I^t} \). Let us identify \( F \) with a sequence of reduced, excisive functors \( \{F(i) : S_s^\infty \to \mathcal{C}_s(i)\}_{i \in I^s} \). Let \( H \) be any object of \( \text{Stab}_\chi(p)_t \), which we can identify with a sequence of reduced excisive functors \( \{H(j) : S_t^\infty \to \mathcal{C}_t(j)\}_{j \in I^t} \). Unwinding the definitions, we can identify \( \text{Map}_{\text{Stab}_\chi(p)}(F,H) \) with the product of the mapping spaces

\[
\text{Map}_{\text{Funct}_{\prod_{\alpha(i)=j} S_s^\infty, \mathcal{D}_\chi(j)}}(e_f(i) \circ \prod_{\alpha(i)=j} F(i), H(j) \circ \wedge(j)),
\]

where \( j \) ranges over the set \( I^t \) and \( \wedge(j) : \prod_{\alpha(i)=j} S_s^\infty \to S_t^\infty \) denotes the iterated smash product functor.

To complete the proof of (1), we wish to show that there exists an object \( G \in \text{Stab}_\chi(p)_t \), and a morphism \( \sigma : F \to G \) in \( \text{Stab}_\chi(p) \) such that composition with \( \sigma \) induces a homotopy equivalence

\[
\text{Map}_{\text{Stab}_\chi(p)}(G,H) \to \text{Map}_{\text{Stab}_\chi(p)}(F,H)
\]

for every object \( H \in \text{Stab}_\chi(p)_t \). To achieve this, we choose \( \sigma \) to correspond to a sequence of natural transformations

\[
\{\beta_j : e_f(j) \circ \prod_{\alpha(i)=j} F(i), G(j) \circ \wedge(j)\}_{j \in I^t}
\]

with the following properties:

(a) If \( \alpha^{-1}\{j\} \) is nonempty, then \( \beta_j \) exhibits the functor \( G(j) \circ \wedge(j) \) as a differential of \( e_f(j) \circ \prod_{\alpha(i)=j} F(i) \)

(b) If \( \alpha^{-1}\{j\} = \emptyset \), then \( e_f(j) \) determines an object \( X \in \mathcal{C}_t(j) \). In this case, we choose \( G(j) \) to correspond to the spectrum \( \Sigma^\infty_+ X \in \text{Sp}(\mathcal{C}_t(j)) \) (see Proposition 6.2.3.16) and \( \beta_j \) to correspond to the unit map \( X \to \Omega^\infty_{\mathcal{C}_t(j)} \Sigma^\infty_+ X \).

Assertion (2) follows immediately from the construction, and assertion (3) follows from the construction together with the description of derivatives supplied by Remark 6.2.3.20 and Example 6.2.1.5. \qed
6.2.6 Uniqueness of Stabilizations

Let $\mathcal{C}^\otimes$ be a differentiable $\infty$-operad. In the last section, we saw that there exists a map of $\infty$-operads $\overline{\mathcal{C}}^\otimes \to \mathcal{C}^\otimes$ which exhibits $\overline{\mathcal{C}}^\otimes$ as a stabilization of $\mathcal{C}^\otimes$. In this section, we will prove that $\overline{\mathcal{C}}^\otimes$ is uniquely determined up to equivalence. For this, it will suffice to show that $\overline{\mathcal{C}}^\otimes$ can be characterized by a universal property (Proposition 6.2.4.15). As in §6.2.5, it will be convenient to work in the more general setting of (local) $\infty$-operad families.

**Definition 6.2.6.1.** Let $p: \mathcal{O}^\otimes \to S \times N(F\text{Fin}_n)$ be a local $S$-family of $\infty$-operads. We will say that $\mathcal{O}^\otimes$ is right exact if the following conditions are satisfied:

(a) The map $p$ is a locally coCartesian fibration (that is, $\mathcal{O}^\otimes$ is a corepresentable local $S$-family of $\infty$-operads).

(b) For each vertex $s \in S$, the $\infty$-category $\mathcal{O}_s$ is pointed and admits finite colimits.

(c) For each edge $s \to t$ in $S$ and each $n \geq 1$, the unique active morphism $\langle n \rangle \to \langle 1 \rangle$ determines a functor

$$\mathcal{O}_{s,n}^\otimes \simeq \mathcal{O}_{(s,n)}^\otimes \to \mathcal{O}_{(t,1)}^\otimes = \mathcal{O}_t$$

which is right exact in each variable.

Suppose that $\mathcal{O}^\otimes$ is a right exact local $S$-family of $\infty$-operads, and that $\mathcal{C}^\otimes$ is a differentiable local $S$-family of $\infty$-operads. We let $\text{Alg}_{\mathcal{O}^\otimes}(\mathcal{C})$ denote the full subcategory of $\text{Fun}_{S \times N(F\text{Fin}_n)}(\mathcal{O}^\otimes, \mathcal{C}^\otimes)$ spanned by those maps $F: \mathcal{O}^\otimes \to \mathcal{C}^\otimes$ with the following properties:

(i) For each $s \in S$, the restriction $F_s: \mathcal{O}_s^\otimes \to \mathcal{C}_s^\otimes$ of $F$ is a map of $\infty$-operads.

(ii) For each $s \in S$, the underlying map of $\infty$-categories $\mathcal{O}_s \to \mathcal{C}_s$ is reduced and excisive.

**Theorem 6.2.6.2.** Let $\mathcal{C}^\otimes \to S \times N(F\text{Fin}_n)$ be a differentiable local $S$-family of $\infty$-operads, let $\overline{\mathcal{C}}^\otimes \to S \times N(F\text{Fin}_n)$ be a stable local $S$-family of $\infty$-operads, and let $U: \overline{\mathcal{C}}^\otimes \to \mathcal{C}^\otimes$ exhibit $\overline{\mathcal{C}}^\otimes$ as a stabilization of $\mathcal{C}^\otimes$ (in the sense of Definition 6.2.5.13). Then, for every right exact local $S$-family of $\infty$-operads $\mathcal{O}^\otimes \to S \times N(F\text{Fin}_n)$, composition with $U$ induces an equivalence of $\infty$-categories $\text{Alg}_{\mathcal{O}^\otimes}(\overline{\mathcal{C}}) \to \text{Alg}_{\mathcal{O}^\otimes}(\mathcal{C})$.

**Remark 6.2.6.3.** Proposition 6.2.4.15 follows immediately from the implication $(1) \Rightarrow (3)$ of Theorem 6.2.6.2, applied in the case $S = \Delta^0$.

The proof of Theorem 6.2.6.2 involves a local analysis on each simplex of $S \times N(F\text{Fin}_n)$. To carry out this analysis, it will be convenient to formulate a “local” version of Theorem 6.2.6.2.

**Definition 6.2.6.4.** Let $\chi: S \to N(F\text{Fin}_n)$ be a map of simplicial sets and let $p: \mathcal{C} \to S$ be a locally coCartesian fibration equipped with a $\chi$-decomposition. We will say that the $\chi$-decomposition of $\mathcal{C}$ is right exact if the following conditions are satisfied:

(a) Let $s \in S$, write $\chi(s) = I_s^*$, and let $\mathcal{C}_s \simeq \prod_{i \in I_s^*} \mathcal{C}_s(i)$ be the corresponding product decomposition of $\mathcal{C}_s$. Then each $\mathcal{C}_s(i)$ is a pointed $\infty$-category which admits finite colimits.

(b) Let $e: s \to t$ be an edge of $S$, so that the associated functor $e_\ast: \mathcal{C}_s \to \mathcal{C}_t$ is given by a product of functors

$$F_j: \prod_{\alpha(i) = j} \mathcal{C}_s(i) \to \mathcal{C}_t(j)$$

(see Remark 6.2.5.9). Then each of the functors $F_j$ is right exact in each variable.

We will say that the $\chi$-decomposition of $\mathcal{C}$ is stable if it satisfies (b) together with the following stronger version of (a):
Let \( s \in S \), write \( \chi(s) = I_s^* \), and let \( C_s \simeq \prod_{i \in I^s} C_s(i) \) be the corresponding product decomposition of \( C_s \). Then each factor \( C_s(i) \) is a stable \( \infty \)-category.

**Notation 6.2.6.5.** Let \( \chi : S \to N(\text{Fin}_\ast) \) be a map of simplicial sets, and suppose we are given locally coCartesian fibrations \( p : \mathcal{C} \to S \) and \( q : \mathcal{D} \to S \) equipped with \( \chi \)-decompositions. For each \( s \in S \), write \( \chi(s) = I_s^* \). Assume that the \( \chi \)-decomposition of \( \mathcal{C} \) is right exact and that each fiber \( \mathcal{D}_s \) of \( q \) admits finite limits. We let \( \text{Exc}_\chi(\mathcal{C}, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}_S(\mathcal{C}, \mathcal{D}) \) spanned by those functors \( F : \mathcal{C} \to \mathcal{D} \) which are decomposition-compatible (Notation 6.2.5.11) and such that the induced map \( \mathcal{C}_s(i) \to \mathcal{D}_s(i) \) is reduced and excisive for each \( s \in S \) and each \( i \in I^s \).

We can now formulate our main result.

**Theorem 6.2.6.6.** Let \( \chi : S \to N(\text{Fin}_\ast) \) be a map of simplicial sets. Suppose we are given a locally differentiable fibration \( p : \mathcal{C} \to S \) equipped with a \( \chi \)-decomposition, and suppose that each fiber \( \mathcal{C}_s \) of \( p \) admits finite colimits. Let \( \overline{\mathcal{C}} : S \to \mathcal{D} \) be another locally coCartesian fibration equipped with a stable \( \chi \)-decomposition, and let \( U \in \text{Exc}_\chi(\overline{\mathcal{C}}, \mathcal{D}) \) (so that \( U \) induces a left exact functor \( \overline{\mathcal{C}}_s \to \mathcal{C}_s \) for each \( s \in S \)). The following conditions are equivalent:

1. The map \( U \) exhibits \( \overline{\mathcal{C}} \) as a stabilization of \( p \) (in the sense of Definition 6.2.5.13).
2. Let \( q : \mathcal{D} \to S \) be a locally coCartesian fibration equipped with a right exact \( \chi \)-decomposition. Then composition with \( U \) induces an equivalence of \( \infty \)-categories
   \[ \text{Exc}_\chi^\ast(\mathcal{D}, \overline{\mathcal{C}}) \to \text{Exc}_\chi^\ast(\mathcal{D}, \mathcal{C}). \]
3. Let \( p : \mathcal{D} \to S \) be a locally coCartesian fibration equipped with a stable \( \chi \)-decomposition. Then composition with \( U \) induces an equivalence of \( \infty \)-categories
   \[ \text{Exc}_\chi^\ast(\mathcal{D}, \overline{\mathcal{C}}) \to \text{Exc}_\chi^\ast(\mathcal{D}, \mathcal{C}). \]

We will give the proof of Theorem 6.2.6.6 at the end of this section.

**Proof of Theorem 6.2.6.6.** Let \( S \) be a simplicial set, let \( \chi : S \times N(\text{Fin}_\ast) \to N(\text{Fin}_\ast) \) denote the projection onto the second factor. To deduce Theorem 6.2.6.6 from Theorem 6.2.6.2, it will suffice to verify the following:

(*) Let \( \mathcal{O}^\circ \to S \times N(\text{Fin}_\ast) \) be a right exact local \( S \)-family of \( \infty \)-operads, let \( \mathcal{C}^\circ \to S \times N(\text{Fin}_\ast) \) be a differentiable local \( S \)-family of \( \infty \)-operads, and let \( U : \mathcal{C}^\circ \to \mathcal{C}^\circ \) exhibit \( \mathcal{C}^\circ \) as a stabilization of \( \mathcal{C}^\circ \).

Regard \( \mathcal{O}^\circ \), \( \mathcal{C}^\circ \), and \( \overline{\mathcal{C}}^\circ \) as endowed with the \( \chi \)-decompositions described in Example 6.2.5.10. Then a map \( F \in \text{Exc}_\chi^\ast(\mathcal{O}^\circ, \overline{\mathcal{C}}^\circ) \) belongs to \( \text{Alg}_{\mathcal{O}}^\circ(\overline{\mathcal{C}}) \) if and only if \( U \circ F \) belongs to \( \text{Alg}_{\mathcal{O}}^\circ(\mathcal{C}) \).

The “only if” direction is obvious. To prove the converse, assume that \( U \circ F \) belongs to \( \text{Alg}_{\mathcal{O}}^\circ(\mathcal{C}) \); we wish to show that \( F \in \text{Alg}_{\mathcal{O}}^\circ(\overline{\mathcal{C}}) \). To prove this, it suffices to verify that for each vertex \( s \in S \), the induced map \( F_s : \mathcal{O}_s^\circ \to \overline{\mathcal{C}}_s^\circ \) is a map of \( \infty \)-operads. Let \( \alpha : \langle m \rangle \to \langle n \rangle \) be a morphism in \( \text{Fin}_\ast \), so that \( \alpha \) determines functors \( \alpha_1 : \mathcal{O}_{s,\langle m \rangle}^\circ \to \mathcal{O}_{s,\langle n \rangle}^\circ \) and \( \alpha_1' : \overline{\mathcal{C}}_{s,\langle m \rangle}^\circ \to \overline{\mathcal{C}}_{s,\langle n \rangle}^\circ \), while \( F \) induces functors \( F_m : \mathcal{O}_{s,\langle m \rangle}^\circ \to \mathcal{C}_{s,\langle m \rangle}^\circ \) and \( F_n : \mathcal{O}_{s,\langle n \rangle}^\circ \to \mathcal{C}_{s,\langle n \rangle}^\circ \), together with a natural transformation \( u_\alpha : \alpha_1 \circ F_m \to F_n \circ \alpha_1 \). We wish to show that \( u_\alpha \) is an equivalence whenever \( \alpha \) is inert. By assumption, \( u_\alpha \) induces an equivalence \( U \circ \alpha_1' \circ F_m \to U \circ F_n \circ \alpha_1 \) of functors from \( \mathcal{O}_{s,\langle m \rangle}^\circ \) to \( \mathcal{O}_{s,\langle n \rangle}^\circ \). Since \( U \) exhibits \( \mathcal{C}^\circ \) as a stabilization of \( \mathcal{O}^\circ \), Proposition 1.4.2.22 implies that composition with \( U \) induces an equivalence of \( \infty \)-categories \( \text{Exc}_\chi^\ast(\mathcal{O}_{s,\langle m \rangle}^\circ, \mathcal{C}_{s,\langle m \rangle}^\circ) \to \text{Exc}_\chi^\ast(\mathcal{O}_{s,\langle n \rangle}^\circ, \mathcal{C}_{s,\langle n \rangle}^\circ) \). It will therefore suffice to show that the functors \( \alpha_1 \circ F_m \) and \( F_n \circ \alpha_1 \) are reduced and excisive (when viewed as functors of a single variable). This is clear: \( F_m \) and \( F_n \) are reduced and excisive (since \( F \in \text{Exc}_\chi^\ast(\mathcal{O}^\circ, \overline{\mathcal{C}}^\circ) \)), the functor \( \alpha_1 \) is right exact (since \( \alpha \) is inert), and the functor \( \alpha_1' \) is left exact (again because \( \alpha \) is inert). \(\square\)
The proof of Theorem 6.2.6.6 will require some preliminaries.

**Lemma 6.2.6.7.** Let $C$ be an $\infty$-category, let $n \geq 1$ be an integer, and suppose we are given a map of simplicial sets $f : \partial \Delta^n \to C$ with $f(0) = X$ and $f(n) = Y$. Let $g : C \to D$ be a functor, and suppose that $g$ induces a homotopy equivalence $\eta : \operatorname{Map}_C(X,Y) \to \operatorname{Map}_D(X,Y)$. Then $g$ induces a homotopy equivalence of Kan complexes

$$\theta : \operatorname{Fun}(\Delta^n,C) \times \operatorname{Fun}(\partial \Delta^n,C) \{ f \} \to \operatorname{Fun}(\Delta^n,D) \times \operatorname{Fun}(\partial \Delta^n,D) \{ g \circ f \}.$$ 

**Proof.** We proceed by induction on $n$. In the case $n = 1$, we can identify $\eta$ with $\theta$ (see Corollary T.4.2.1.8) so there is nothing to prove. If $n > 1$, we can choose an integer $0 < i < n$. Let $f_0 = f|\Lambda^n_i$. We have a diagram of fiber sequences

$$\begin{array}{ccc}
\operatorname{Fun}(\Delta^n,C) \times \operatorname{Fun}(\partial \Delta^n,C) \{ f \} & \to & \operatorname{Fun}(\Delta^n,D) \times \operatorname{Fun}(\partial \Delta^n,D) \{ g \circ f \} \\
\downarrow & & \downarrow \\
\operatorname{Fun}(\Delta^n,C) \times \operatorname{Fun}(\Lambda^n_i,C) \{ f_0 \} & \to & \operatorname{Fun}(\Delta^n,D) \times \operatorname{Fun}(\Lambda^n_i,D) \{ g \circ f_0 \} \\
\downarrow & & \downarrow \\
\operatorname{Fun}(\partial \Delta^n,C) \times \operatorname{Fun}(\Lambda^n_i,C) \{ f_0 \} & \to & \operatorname{Fun}(\partial \Delta^n,D) \times \operatorname{Fun}(\Lambda^n_i,D) \{ g \circ f_0 \}.
\end{array}$$

Since the inclusion $\Lambda^n_i$ is inner anodyne, the domain and codomain of $\theta'$ are contractible. We are therefore reduced to proving that $\theta''$ is a homotopy equivalence. Let $f_1$ denote the restriction of $f$ to the face of $\Delta^n$ opposite the $i$th vertex. Then $\theta''$ is a (homotopy) pullback of the map

$$\theta : \operatorname{Fun}(\Delta^{n-1},C) \times \operatorname{Fun}(\partial \Delta^{n-1},C) \{ f_1 \} \to \operatorname{Fun}(\Delta^{n-1},D) \times \operatorname{Fun}(\partial \Delta^{n-1},D) \{ g \circ f_1 \},$$

and therefore a homotopy equivalence by the inductive hypothesis. \hfill \square

**Lemma 6.2.6.8.** Let $n \geq 0$ be an integer, and let $Y$ be the simplicial subset of $\Delta^n \times \Delta^1$ given by the union of $\partial \Delta^n \times \Delta^1$ and $\Delta^n \times \partial \Delta^1$. Then the inclusion $Y \hookrightarrow \Delta^n \times \Delta^1$ factors as a composition $Y \hookrightarrow X \xrightarrow{j} \Delta^n \times \Delta^1$, where $i$ is inner anodyne and $j$ fits into a pushout diagram

$$\begin{array}{ccc}
\partial \Delta^{n+1} & \to & \Delta^{n+1} \\
\downarrow & & \downarrow \\
X & \to & \Delta^n \times \Delta^1 \\
\downarrow \sigma & & \downarrow \\
\sigma(0) &=& (0,0) \quad \text{and} \quad \sigma(n+1) = (n,1).
\end{array}$$

**Proof.** Use the filtration described in the proof of Proposition T.2.1.2.6. \hfill \square

**Lemma 6.2.6.9.** Let $C = (\Delta^1)^n$ denote a cube of dimension $n$, let $v = (0, \ldots, 0)$ be the initial vertex of $C$, and let $w = (1, \ldots, 1)$ be the final vertex of $C$. Then the inclusion $\partial C \hookrightarrow C$ factors as a composition

$$\partial C \hookrightarrow X \xrightarrow{j} C,$$

where $i$ is inner anodyne and $j$ fits into a pushout diagram

$$\begin{array}{ccc}
\partial \Delta^n & \to & \Delta^n \\
\downarrow & & \downarrow \\
X & \to & C \\
\downarrow \sigma & & \downarrow \\
\sigma(0) &=& v \quad \text{and} \quad \sigma(n) = w.
\end{array}$$
Proof. We proceed by induction on \( n \), the case \( n = 0 \) being obvious. If \( n > 0 \), set \( C' = (\Delta^1)^{n-1} \) and use the inductive hypothesis to factor the inclusion \( \partial C' \to C' \) as a composition \( \partial C' \xrightarrow{\iota'} X' \xrightarrow{\iota} C' \). Write \( C = C' \times \Delta^1 \), and let \( Y \) be the simplicial subset of \( C \) given by the union of \( X' \times \Delta^1 \) and \( C' \times (\partial \Delta^1) \). Then the inclusion \( \partial C \to Y \) is inner anodyne (Corollary T.2.3.2.4). The inclusion \( Y \to C \) is a pushout of the inclusion
\[
(\partial \Delta^{n-1} \times \Delta^1) \coprod_{\partial \Delta^{n-1} \times (\partial \Delta^1)} (\Delta^{n-1} \times \partial \Delta^1) \to \Delta^{n-1} \times \Delta^1.
\]
We now conclude by applying Lemma 6.2.6.8. \( \square \)

**Lemma 6.2.6.10.** Let \( C = (\Delta^1)^n \) denote a cube of dimension \( n > 0 \), let \( \mathcal{C} \) be an \( \infty \)-category, and let \( f : \partial C \to \mathcal{C} \) be a functor carrying the initial vertex of \( C \) to an object \( X \in \mathcal{C} \) and the final vertex of \( C \) to an object \( Y \in \mathcal{C} \). Suppose that \( g : \mathcal{C} \to \mathcal{D} \) is a functor of \( \infty \)-categories which induces a homotopy equivalence \( \operatorname{Map}(X,Y) \to \operatorname{Map}_\mathcal{D}(g(X),g(Y)) \). Then \( g \) induces a homotopy equivalence of Kan complexes
\[
\operatorname{Fun}(C,\mathcal{C}) \times_{\operatorname{Fun}(\partial C,\mathcal{C})} \{ f \} \to \operatorname{Fun}(C,\mathcal{D}) \times_{\operatorname{Fun}(\partial C,\mathcal{D})} \{ g \circ f \}.
\]

**Proof.** Combine Lemmas 6.2.6.7 and 6.2.6.9. \( \square \)

**Lemma 6.2.6.11.** Let \( I \) be a finite set. Suppose we are given differentiable \( \infty \)-categories \( \{ \mathcal{D}_i \}_{i \in I} \) and \( \mathcal{E} \) which admit finite colimits, a pair of functors
\[
F : \prod_{i \in I} \mathcal{D}_i \to \mathcal{E} \quad f : \prod_{i \in I} \operatorname{Sp}(\mathcal{D}_i) \to \operatorname{Sp}(\mathcal{E}),
\]
and a natural transformation \( \epsilon : F \circ \prod_{i \in I} \Omega^\infty_{\mathcal{D}_i} \to \Omega^\infty_{\mathcal{E}} \circ f \) which exhibits \( f \) as a derivative of \( F \). Suppose further that we are given a collection of pointed \( \infty \)-categories \( \{ \mathcal{E}_i \}_{i \in I} \) which admit finite colimits, together with functors
\[
\{ G_i : \mathcal{E}_i \to \operatorname{Sp}(\mathcal{D}_i) \}_{i \in I} \quad H : \prod_{i \in I} \mathcal{E}_i \to \operatorname{Sp}(\mathcal{E})
\]
where each \( G_i \) is right exact and \( H \) is right exact in each variable. Then composition with \( \epsilon \) induces a homotopy equivalence
\[
\theta : \operatorname{Map}_\mathcal{C}(\prod_{i \in I} e_i, \mathcal{E})(f \circ \prod_{i \in I} G_j, H) \to \operatorname{Map}_\mathcal{C}(\prod_{i \in I} e_i, \mathcal{E})(F \circ \prod_{i \in I} (\Omega^\infty_{\mathcal{D}_i} \circ G_j), \Omega^\infty_{\mathcal{E}} \circ H).
\]

**Proof.** We will assume that the set \( I \) is empty (otherwise the statement is a tautology). Since the functors \( H \) and \( f \circ \prod_{i \in I} G_i \) are multilinear, Proposition 1.4.2.22 implies that composition with \( \Omega^\infty_{\mathcal{E}} \) induces a homotopy equivalence
\[
\operatorname{Map}_\mathcal{C}(\prod_{i \in I} e_i, \mathcal{E})(f \circ \prod_{i \in I} G_j, H) \to \operatorname{Map}_\mathcal{C}(\prod_{i \in I} e_i, \mathcal{E})(\Omega^\infty_{\mathcal{E}} \circ f \circ \prod_{i \in I} G_i, \Omega^\infty_{\mathcal{E}} \circ H).
\]
It will therefore suffice to show that \( \epsilon \) induces a natural transformation \( \epsilon' : F \circ \prod_{i \in I} \Omega^\infty_{\mathcal{D}_i} \circ \prod_{i \in I} G_i \to \Omega^\infty_{\mathcal{E}} \circ f \circ \prod_{i \in I} G_j \) which exhibits \( \Omega^\infty_{\mathcal{E}} \circ f \circ \prod_{i \in I} G_j \) as a differential of \( F \circ \prod_{i \in I} \Omega^\infty_{\mathcal{D}_i} \circ \prod_{i \in I} G_i \). This follows from Remark 6.2.3.4 together with Proposition 6.2.3.15. \( \square \)

**Proof of Theorem 6.2.6.6.** The implication \( (2) \Rightarrow (3) \) is obvious. Assume that \( (1) \Rightarrow (2) \) for the moment; we will show that \( (3) \Rightarrow (1) \). Let us regard \( p : \mathcal{C} \to S \) as fixed. It is clear that if there exists a diagram
\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{U} & \mathcal{E} \\
\downarrow p & & \downarrow \\
S & \xrightarrow{p} & \mathcal{E}
\end{array}
\]
where \( q \) is a locally coCartesian fibration equipped with a stable \( \chi \)-decomposition satisfying condition (3), then \( \mathcal{C} \) is well-defined up to equivalence fiberwise over \( S \). Consequently, to prove that (3) \( \Rightarrow \) (1), it will suffice to exhibit such a diagram which having the additional property that \( U \) exhibits \( \mathcal{C} \) as a stabilization of \( \mathcal{C} \). Since (1) \( \Rightarrow \) (2) \( \Rightarrow \) (3), it suffices to show that \( p \) admits a stabilization, which follows from Theorem 6.2.5.25.

It remains to prove that (1) \( \Rightarrow \) (2). Assume that \( U : \mathcal{C} \to \mathcal{C} \) exhibits \( \mathcal{C} \) as a stabilization of \( p \), and let \( q : \mathcal{D} \to S \) be a locally coCartesian fibration equipped with a right exact \( \chi \)-decomposition. We wish to prove that composition with \( U \) induces an equivalence of \( \infty \)-categories

\[
\text{Exc}_*^\chi(\mathcal{D}, \mathcal{C}) \to \text{Exc}_*^\chi(\mathcal{D}, \mathcal{C}).
\]

For this, it suffices to show that for every simplicial set \( K \), the induced map \( \text{Fun}(K, \text{Exc}_*^\chi(\mathcal{D}, \mathcal{C})) \to \text{Fun}(K, \text{Exc}_*^\chi(\mathcal{D}, \mathcal{C})) \) restricts to a homotopy equivalence \( \text{Fun}(K, \text{Exc}_*^\chi(\mathcal{D}, \mathcal{C})) \to \text{Fun}(K, \text{Exc}_*^\chi(\mathcal{D}, \mathcal{C})) \) between the underlying Kan complexes. Replacing \( \mathcal{C} \) by \( \text{Fun}(K, \mathcal{C}) \times_{\text{Fun}(K, S)} S \) and \( \mathcal{C} \) by \( \text{Fun}(K, \mathcal{C}) \times_{\text{Fun}(K, S)} S \), we are reduced to proving that the map \( \theta : \text{Exc}_*^\chi(\mathcal{D}, \mathcal{C}) \to \text{Exc}_*^\chi(\mathcal{D}, \mathcal{C}) \) is a homotopy equivalence of Kan complexes.

For every map of simplicial sets \( T \to S \), let \( \mathcal{D}_T = T \times_S \mathcal{D}, \mathcal{C}_T = T \times_S \mathcal{C}, \) and \( \mathcal{C}_T = T \times_S \mathcal{C} \). Set

\[
X_T = \text{Exc}_*^\chi(T, \mathcal{C}_T), \quad Y_T = \text{Exc}_*^\chi(T, \mathcal{C}_T).
\]

Composition with the map \( U \) induces a map of Kan complexes \( \theta_T : X_T \to Y_T \). We will prove that \( \theta_T \) is a homotopy equivalence of Kan complexes, for every map \( T \to S \). Write \( T \) as a union of its skeleta

\[
\emptyset = \text{sk}^{-1} T \subseteq \text{sk}^0 T \subseteq \text{sk}^1 T \subseteq \cdots.
\]

Then \( \theta_T \) is a homotopy limit of the tower of maps \( \{ \theta_{sk^n T} \} \). It will therefore suffice to prove that each of the morphisms \( \theta_{sk^n T} \) is a homotopy equivalence. We may therefore assume without loss of generality that \( T \) has dimension \( \leq n \), for some integer \( n \). We proceed by induction on \( n \), the case \( n = -1 \) being trivial. Assume \( n \geq 0 \) and let \( A \) denote the set of \( n \)-simplices of \( T \), so that we have a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
A \times \partial \Delta^n & \to & A \times \Delta^n \\
\downarrow & & \downarrow \\
\text{sk}^{n-1} T & \to & T,
\end{array}
\]

which determines a homotopy pullback diagram

\[
\begin{array}{ccc}
\theta_{A \times \partial \Delta^n} & \leftarrow & \theta_{A \times \Delta^n} \\
\downarrow & & \downarrow \\
\theta_{\text{sk}^{n-1} T} & \leftarrow & \theta_T.
\end{array}
\]

Using the inductive hypothesis, we deduce that \( \theta_{A \times \partial \Delta^n} \) and \( \theta_{\text{sk}^{n-1} T} \) are homotopy equivalences. Consequently, to prove that \( \theta_T \) is a homotopy equivalence, it will suffice to show that \( \theta_{A \times \Delta^n} \) is a homotopy equivalence. Note that \( \theta_{A \times \Delta^n} \) is a product of the functors \( \theta_{\{a\} \times \Delta^n} \) (where the product is taken over the elements \( a \in A \)). It will therefore suffice to show that each of the morphisms \( \theta_{\{a\} \times \Delta^n} \) is a homotopy equivalence. Replacing \( S \) by \( \{a\} \times \Delta^n \), we may reduce to the case where \( S \) is an \( n \)-simplex for some \( n \geq 0 \).

We first treat the case where \( n = 0 \), so that \( S \) consists of a single vertex. The functor \( \chi \) carries this vertex to a pointed finite set \( I_* \), and the \( \chi \)-decompositions of \( \mathcal{C}, \mathcal{C}, \) and \( \mathcal{D} \) give equivalences

\[
\mathcal{C} \simeq \prod_{i \in I} \mathcal{C}(i) \quad \mathcal{C} = \prod_{i \in I} \mathcal{C}(i) \quad \mathcal{D} \simeq \prod_{i \in I} \mathcal{D}(i)
\]
Unwinding the definitions, we can identify $\theta_S$ with the product of the maps

$$\text{Exc}_s(D(i), \mathcal{C}(i))^\approx \to \text{Exc}_s(D(i), \mathcal{C}(i))^\approx.$$ 

Since $U$ satisfies condition (1), each of these functors is a homotopy equivalence by Proposition 1.4.2.22.

We now treat the case $n > 0$. For $0 \leq i \leq n$, write $\chi(i) = J_i^i$ for some finite set $J_i$. Since $p : D \to \Delta^n$ is a locally coCartesian fibration, Proposition 6.2.2.28 guarantees the existence of a simplicial functor $\mathcal{F} : \mathcal{C}[\Delta^n] \to \Delta^n \setminus \Delta_i^i$ and a map $u : M(\mathcal{F}) \to D$ which induces categorical equivalences $\mathcal{F}(i) \to D \times \Delta_i^i(i)$ for $0 \leq i \leq n$. We may assume without loss of generality that $\mathcal{F}$ is a fibrant diagram, so that each $\mathcal{F}(i)$ is an $\infty$-category. Let $D' = M(\mathcal{F})$. For every simplicial subset $T \subseteq \Delta^n$, let $D'_T = D' \times \Delta^n T$ (which is a categorical equivalence of $\infty$-categories if $T$ is a simplex). Let $X'(T)$ denote the essential image of $X(T)$ in $\text{Fun}_T(D'_T, \mathcal{C}_T)^\approx$ and let $Y'(T)$ denote the essential image of $Y(T)$ in $\text{Fun}_T(D'_T, \mathcal{C}_T)^\approx$. The evident maps $X(T) \to X'(T)$ and $Y(T) \to Y'(T)$ are homotopy equivalences. It follows from the inductive hypothesis that the canonical map $X'(T) \to Y'(T)$ is a homotopy equivalence for every proper subset $T \subseteq \Delta^n$, and we wish to show that $X'(T) \to Y'(T)$ is an equivalence when $T = \Delta^n$. For this, it suffices to show that the diagram of spaces $\sigma$:

$$
\begin{array}{ccc}
X'(\Delta^n) & \longrightarrow & Y'(\Delta^n) \\
\downarrow & & \downarrow \\
X'(\partial \Delta^n) & \longrightarrow & Y'(\partial \Delta^n)
\end{array}
$$

is a homotopy pullback square.

Let $\mathcal{X}$ denote the full subcategory of $\text{Fun}(\mathcal{F}(0), \mathcal{C})$ spanned by those functors $F$ which satisfy the following condition:

(*) There exists a vertex $i \in \Delta^n$ such that $F$ factors through $\mathcal{C}_i$ (this condition is actually automatic, since the $\infty$-category $\mathcal{C}_i$ is pointed). Let $\alpha : J^p \to J^i$ denote the map of pointed finite sets determined by $\chi$. The $\chi$-decompositions of $\mathcal{C}$ and $D$ determine equivalences of $\infty$-categories

$$D_0 \simeq \prod_{j \in J^p} D_0(j) \quad \mathcal{C}_i = \prod_{j \in J^i} \mathcal{C}_i(j^i).$$

Then $F$ is equivalent to a composition

$$\mathcal{F}(0) \simeq \prod_{j \in J^p} D_0(j) \prod_{j \in J^i} F_{j^i} \prod_{j \in J^i} \mathcal{C}_i(k) \simeq \mathcal{C}_i$$

where each of the functors $F_k : \prod_{\alpha(j) = k} D_0(j) \to \mathcal{C}_i$ is reduced and excisive in each variable.

Define $\mathcal{X} \subseteq \text{Fun}(\mathcal{F}(0), \mathcal{C})$ similarly. Let $C = (\Delta^1)^n$ denote a cube of dimension $n$. Unwinding the definitions, we obtain a pushout diagram of simplicial sets

$$
\begin{array}{ccc}
\partial C \times \mathcal{F}(0) & \longrightarrow & C \times \mathcal{F}(0) \\
\downarrow & & \downarrow \\
D'_\partial \Delta^n & \longrightarrow & D'_{\Delta^n},
\end{array}
$$

compatible with a projection map $\pi : C \to \Delta^n$. Set

$$X'' = \text{Fun}(C, \mathcal{X})^\approx \times \text{Fun}(\partial C, \Delta^n)^\approx \{\pi\} \quad X_0'' = \text{Fun}(\partial C, \mathcal{X})^\approx \times \text{Fun}(\partial C, \Delta^n)^\approx \{\pi| \partial C\}$$

$$Y'' = \text{Fun}(C, \mathcal{X})^\approx \times \text{Fun}(\partial C, \Delta^n)^\approx \{\pi\} \quad Y_0'' = \text{Fun}(\partial C, \mathcal{X})^\approx \times \text{Fun}(\partial C, \Delta^n)^\approx \{\pi| \partial C\}$$
6.3. THE CHAIN RULE

We have a commutative diagram

\[
\begin{array}{ccc}
X'(\Delta^n) & \longrightarrow & Y'(\Delta^n) \\
\downarrow & & \downarrow \\
X'((\partial \Delta^n) & \longrightarrow & Y'(\partial \Delta^n) \\
\end{array}
\]

where right square is a homotopy pullback. Consequently, to prove that \( \sigma \) is a homotopy pullback square, it will suffice to show that the outer rectangle is a homotopy pullback square. This outer rectangle fits into a commutative diagram

\[
\begin{array}{ccc}
X'(\Delta^n) & \longrightarrow & X'' \\
\downarrow & & \downarrow \\
X'(\partial \Delta^n) & \longrightarrow & X''_0 \\
\end{array}
\]

where the left square is a homotopy pullback diagram. We are therefore reduced to showing that the right square in this diagram is a homotopy pullback. For this, it suffices to show that for every point \( x \) where the left square is a homotopy pullback diagram. We are therefore reduced to showing that the right square is a homotopy pullback. Consequently, to prove that \( \sigma \) is a homotopy pullback, it will suffice to show that the outer rectangle is a homotopy pullback square. This outer rectangle fits into a commutative diagram

\[
\begin{array}{ccc}
X'(\Delta^n) & \longrightarrow & X'' \\
\downarrow & & \downarrow \\
X'(\partial \Delta^n) & \longrightarrow & X''_0 \\
\end{array}
\]

where the left square is a homotopy pullback diagram. We are therefore reduced to showing that the right square in this diagram is a homotopy pullback. For this, it suffices to show that for every point \( x \) where \( X'' \times X''_0 \{ x \} \rightarrow Y'' \times Y''_0 \{ x \} \) is a homotopy equivalence of Kan complexes. Let us identify \( x \) with a map \( f : \partial C \rightarrow \mathcal{X} \); we wish to show that the projection map \( g : \mathcal{X} \rightarrow \mathcal{X} \) induces a homotopy equivalence

\[
\text{Fun}(C, \mathcal{X}) \times_{\text{Fun}(\partial C, \mathcal{X})} \{ f \} \rightarrow \text{Fun}(C, \mathcal{X}) \times_{\text{Fun}(\partial C, \mathcal{X})} \{ g \circ f \}.
\]

Let \( F, F' \in \mathcal{X} \) be the images under \( f \) of the initial and final vertices of \( C \), respectively. Using Lemma 6.2.6.9, we are reduced to proving that \( g \) induces a homotopy equivalence \( \text{Map}_\mathcal{X}(F, F') \rightarrow \text{Map}_\mathcal{X}(g(F), g(F')) \). This follows from Lemma 6.2.6.11 (after an unpacking of definitions).

\[
\square
\]

6.3 The Chain Rule

Let \( \mathcal{E} \) and \( \mathcal{D} \) be compactly generated pointed \( \infty \)-categories, and let \( F : \mathcal{E} \rightarrow \mathcal{D} \) be a reduced functor which preserves filtered colimits. In §6.1.2, we saw how to associate to \( F \) a tower of approximations

\[
\cdots \rightarrow P_3(F) \rightarrow P_2(F) \rightarrow P_1(F) \rightarrow P_0(F) \simeq *,
\]

where each \( P_n F \) is \( n \)-excisive. Roughly speaking, we can think of this tower as a providing a filtration of \( F \) whose “successive quotients” \( D_n(F) = \text{fib}(P_n(F) \rightarrow P_{n-1}(F)) \) are \( n \)-homogeneous. According to Theorem 6.1.4.7, each functor \( D_n \) is determined by its symmetric cross-effect \( \text{cr}_n D_n(F) \in \text{SymFun}^\text{lin}_\infty(\mathcal{E}, \mathcal{D}) \). Corollary 6.2.3.22 supplies an equivalence of \( \infty \)-categories

\[
\theta : \text{Exc}_* (\text{Sp}(\mathcal{E})^n, \text{Sp}(\mathcal{D})) \rightarrow \text{Exc}_* (\mathcal{E}^n, \mathcal{D}).
\]

Consequently, the functor \( \text{cr}_n D_n(F) : \mathcal{E}^n \rightarrow \mathcal{D} \) is given by the composition

\[
\mathcal{E}^n \xrightarrow{\Sigma^n} \text{Sp}(\mathcal{E})^n \xrightarrow{\partial_n(F)} \text{Sp}(\mathcal{D}) \xrightarrow{\Omega^n} \mathcal{D}
\]

for some functor \( \partial_n(F) : \text{Sp}(\mathcal{E})^n \rightarrow \text{Sp}(\mathcal{D}) \) which is excisive in each variable. We will refer to \( \partial_n(F) \) as the \( n \)th derivative of the functor \( F \).

In this section, we will be concerned with the following:

**Question 6.3.0.1.** Suppose that \( F : \mathcal{E} \rightarrow \mathcal{D} \) and \( G : \mathcal{D} \rightarrow \mathcal{E} \) are reduced functors between pointed compactly generated \( \infty \)-categories which preserve filtered colimits. Can one compute the derivatives of the composite functor \( G \circ F \) in terms of the derivatives of \( G \) and \( F \)?
To address Question 6.3.0.1, it will be convenient to introduce some terminology. Note that the equivalence of $\infty$-categories $\theta$ is equivariant with respect to the action of the symmetric group $\Sigma^n$. It follows that each of the functors $\partial_n(F) : \Sp(\mathcal{E})^n \to \Sp(\mathcal{D})$ is invariant under permutations of its arguments. More precisely, $\partial_n(F)$ underlies a symmetric multilinear functor $\partial_n(F) \in \SymFun^n_{\text{lin}}(\Sp(\mathcal{E}), \Sp(\mathcal{D}))$.

**Definition 6.3.0.2.** Let $\mathcal{E}$ and $\mathcal{D}$ be stable $\infty$-categories. A symmetric sequence of functors from $\mathcal{E}$ to $\mathcal{D}$ is a collection of symmetric multilinear functors $\{F_n : \SymFun^n_{\text{lin}}(\mathcal{E}, \mathcal{D})\}_{n \geq 1}$. We let $\SSeq(\mathcal{E}, \mathcal{D})$ denote the $\infty$-category $\prod_{n \geq 1} \SymFun^n_{\text{lin}}(\mathcal{E}, \mathcal{D})$ of symmetric sequences from $\mathcal{E}$ to $\mathcal{D}$.

**Remark 6.3.0.3.** We will generally denote a symmetric sequence of functors $\{F_n \in \SymFun^n_{\text{lin}}(\mathcal{E}, \mathcal{D})\}_{n \geq 1}$ simply by $F \in \SSeq(\mathcal{E}, \mathcal{D})$.

**Remark 6.3.0.4.** Let $\mathcal{E}$ and $\mathcal{D}$ be stable $\infty$-categories. We can think of a symmetric sequence $F_* \in \SSeq(\mathcal{E}, \mathcal{D})$ as a collection of functors $F_I : \mathcal{E}^I \to \mathcal{D}$ which are exact in each variable, defined for every nonempty finite set $I$ and depending functorially on $I$.

**Example 6.3.0.5.** Let $F : \mathcal{E} \to \mathcal{D}$ be a reduced functor between compactly generated pointed $\infty$-categories, and assume that $F$ commutes with filtered colimits. Then the collection of derivates $\{\partial_n(F)\}_{n \geq 1}$ is a symmetric sequence from $\Sp(\mathcal{E})$ to $\Sp(\mathcal{D})$, which we will denote by $\partial_*(F) \in \SSeq(\Sp(\mathcal{E}), \Sp(\mathcal{D}))$.

Suppose we are given a triple of stable $\infty$-categories $\mathcal{E}$, $\mathcal{D}$, and $\mathcal{E}$. There is a composition product

$$\circ : \SSeq(\mathcal{D}, \mathcal{E}) \times \SSeq(\mathcal{E}, \mathcal{D}) \to \SSeq(\mathcal{E}, \mathcal{E}),$$

which is given informally by $G_* \circ F_* = H_*$, with

$$H_I = \bigoplus_{\mathcal{E}} G_{I/E} \circ \{F_J\}_{J \in I/E}$$

where the sum is taken over all equivalence relations $E$ on the nonempty finite set $I$. This composition product is coherently associative. In particular, if $\mathcal{E}$ is a compactly generated stable $\infty$-category, then $\SSeq(\mathcal{E}, \mathcal{E})$ can be regarded as a monoidal $\infty$-category. If $\mathcal{D}$ is another compactly generated stable $\infty$-category, then $\SSeq(\mathcal{E}, \mathcal{D})$ is left tensored over $\SSeq(\mathcal{D}, \mathcal{D})$ and right tensored over $\SSeq(\mathcal{E}, \mathcal{E})$.

**Remark 6.3.0.6.** We will not give a precise definition for the composition product of symmetric sequences in this book. The reader can regard the above discussion as heuristic (though, with some effort, it can be made precise). Note that the associativity of the composition product described above depends crucially on the fact that we are working with stable $\infty$-categories, and that all functors are assumed to be exact.

A complete answer to Question 6.3.0.1 can be given as follows:

**Conjecture 6.3.0.7 (Chain Rule).** (1) Let $\mathcal{E}$ be a compactly generated pointed $\infty$-category, and let $\text{id}_\mathcal{E} : \mathcal{E} \to \mathcal{E}$ denote the identity functor. Then the symmetric sequence $\partial_*(\text{id}_\mathcal{E})$ is equipped with a coherently associative multiplication: that is, it can be regarded as an algebra object of the monoidal $\infty$-category $\SSeq(\Sp(\mathcal{E}), \Sp(\mathcal{E}))$.

(2) Let $F : \mathcal{E} \to \mathcal{D}$ be a reduced functor between compactly generated pointed $\infty$-categories which commutes with filtered colimits. Then $\partial_*(F)$ can be regarded as an $\partial_*(\text{id}_\mathcal{D}) \cdot \partial_*(\text{id}_\mathcal{E})$ bimodule object of $\SSeq(\Sp(\mathcal{E}), \Sp(\mathcal{D}))$.

(3) Let $F : \mathcal{E} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{E}$ be reduced functors between compactly generated pointed $\infty$-categories which commute with filtered colimits. Then there is a canonical equivalence

$$\partial_*(G \circ F) \simeq \partial_*(G) \otimes_{\partial_*(\text{id}_\mathcal{D})} \partial_*(F)$$

in the $\infty$-category of $\partial_*(\text{id}_\mathcal{E}) \cdot \partial_*(\text{id}_\mathcal{D})$ bimodule objects of $\SSeq(\Sp(\mathcal{E}), \Sp(\mathcal{D}))$. 
Remark 6.3.0.8. In the case where $\mathcal{C}, \mathcal{D}, \mathcal{E} \in \{\text{Sp}, S_*\}$, Conjecture 6.3.0.7 was proven (in a different setting) by Arone and Ching. We refer the reader to [2] for more details.

Remark 6.3.0.9. If we restrict our attention to first derivatives, Conjecture 6.3.0.7 reduces to (the single variable version of) Theorem 6.2.1.22.

To arrive at a more precise formulation of Conjecture 6.3.0.7, it is convenient to use the language of corepresentable $\infty$-operads developed in §6.2.4. Suppose that $\mathcal{O}^{\otimes}$ is a stable $\infty$-operad (see Definition 6.2.4.10). For each $n > 0$, Remark 6.2.4.4 provides a functor $\otimes^n : \mathcal{O}^{\otimes} \to \mathcal{O}$, which is exact in each variable. We can regard the collection of functors $\{\otimes^n\}_{n \geq 1}$ as a symmetric sequence from $\mathcal{O}$ to itself, which we will denote by $\otimes^* \in \text{SSeq}(\mathcal{O}, \mathcal{O})$. Let $I$ be a finite set and let $\text{Equiv}(I)$ denote the set of all equivalence relations on $I$. For every equivalence relation $E$ on $I$, Remark 6.2.4.8 supplies a natural transformation of functors

$$\otimes^I \to \otimes^I/E \circ \prod_{J \in I/E} \otimes^J.$$ 

Taking the direct sum of these natural transformations over all $E$, we obtain a map $\otimes^I \to (\otimes^* \circ \otimes^*)^I$. Allowing $I$ to vary, we get a map of symmetric sequences $\delta : \otimes^* \to \otimes^* \circ \otimes^*$.

Let us regard the stable $\infty$-operad $\mathcal{O}^{\otimes}$ as encoded by a locally coCartesian fibration $p : \mathcal{O}^{\otimes} \to N(\text{Fin}_*)$. The underlying $\infty$-category $\mathcal{O}$ can be recovered by studying the fibers of $p$ over vertices of $N(\text{Fin}_*)$ (in fact, over the single vertex $(1) \in N(\text{Fin}_*)$), the symmetric sequence $\otimes^*$ can be recovered by studying the restriction of $p$ to edges of $N(\text{Fin}_*)$, and the comultiplication map $\delta$ can be recovered by studying the restriction of $p$ to 2-simplices of $N(\text{Fin}_*)$. We can regard the entire locally coCartesian fibration $p$ as witnessing the fact that the comultiplication $\delta$ is associative up coherent homotopy. In other words, a corepresentable $\infty$-operad $\mathcal{O}^{\otimes}$ determines a stable $\infty$-category $\mathcal{O}$ together with a coalgebra object of the monoidal $\infty$-category $\text{SSeq}(\mathcal{O}, \mathcal{O})$.

Remark 6.3.0.10. Let $\mathcal{O}$ be a stable $\infty$-category. With some effort, one can show that the construction sketched above underlies an equivalence between the following two types of data:

(a) Coalgebra objects $F^*$ of $\text{SSeq}(\mathcal{O}, \mathcal{O})$ for which the counit map restricts to an equivalence $F^1 \simeq \text{id}_\mathcal{O}$.

(b) Stable unital $\infty$-operads $\mathcal{O}^{\otimes}$ having underlying $\infty$-category $\mathcal{O}$.

Since we will not need this fact, we will not give a precise formulation here.

Example 6.3.0.11. Let $\mathcal{O}^{\otimes} \to N(\text{Fin}_*)$ be a stable $\infty$-operad. Suppose that the underlying $\infty$-category $\mathcal{O}$ is the $\infty$-category of spectra, and that each of the functors $\otimes^n : \mathcal{O}^{\otimes} \to \mathcal{O}$ preserves filtered colimits. Then each of the functors $\otimes^n : \mathcal{O}^{\otimes} \to \mathcal{O}$ preserves small colimits separately in each variable, and is therefore given by the formula

$$(X_1, X_2, \ldots, X_n) \mapsto E_n \otimes X_1 \otimes \cdots \otimes X_n$$

for some spectrum $E_n$ (given concretely by $E_n = \otimes^n \langle S \rangle_{1 \leq i \leq n}$). Then the collection $\{E_n\}_{n \geq 1}$ can be regarded as a cooperad in $\infty$-category of spectra. That is, each $E_n$ is equipped with an action of the symmetric group $\Sigma_n$, and we have coproduct maps

$$E_{n_1 + \cdots + n_k} \to E_k \otimes \bigotimes_{1 \leq i \leq k} E_{n_i}$$

which satisfy an associative law up to coherent homotopy.

Warning 6.3.0.12. The dictionary provided by Example 6.3.0.11 poses some danger of creating confusion. To every cooperad $\{E_n\}_{n \geq 1}$ in spectra (in the sense of classical homotopy theory), we can reverse engineer the construction of Example 6.3.0.11 to produce a unital stable $\infty$-operad $\mathcal{O}^{\otimes} \to N(\text{Fin}_*)$ (in the sense of Definition 6.2.4.10). In other words, the same mathematical structure has two incarnations: first, as a cooperad (enriched in spectra) and second, as an operad (with several colors, enriched in spaces). The first perspective is useful for comparing the constructions given here with the existing literature ([2]). However, we will avoid it in what follows, to avoid conflict with the terminology established earlier in this book.
CHAPTER 6. THE CALCULUS OF FUNCTORS

Using the above dictionary and the canonical equivalence $\text{SSeq}(\mathcal{O}, \mathcal{O})^{op} \simeq \text{SSeq}(\mathcal{O}^{op}, \mathcal{O}^{op})$, we can now give a precise formulation of the first assertion of Conjecture 6.3.0.7:

**Conjecture 6.3.0.13.** Let $\mathcal{C}$ be a compactly generated pointed $\infty$-category. Then there exists a unital stable $\infty$-operad $\mathcal{O}^\otimes$ with the following properties:

(a) The underlying $\infty$-category of $\mathcal{O}^\otimes$ is given by $\mathcal{O} \simeq \text{Sp}(\mathcal{C})^{op}$.

(b) For each $n \geq 1$, the tensor product functor $\otimes^n : \mathcal{O}^n \to \mathcal{O}$ is equivalent to (the opposite of) the functor $\partial_n(\text{id}_\mathcal{C}) : \text{Sp}(\mathcal{C})^n \to \text{Sp}(\mathcal{C})$.

Using the ideas developed in §6.2, we can immediately deduce a close relative of Conjecture 6.3.0.13. Let $\mathcal{C}$ be a compactly generated pointed $\infty$-category, and let $\mathcal{C}^\times$ be the associated Cartesian symmetric monoidal $\infty$-category. Then $\mathcal{C}^\times$ is a differentiable $\infty$-operad, so it admits a stabilization $\mathcal{O}^\otimes$ (Proposition 6.2.4.14). Note that since $\mathcal{C}$ is pointed, the $\infty$-operad $\mathcal{O}^\otimes$ is unital. This proves the following:

**Proposition 6.3.0.14.** Let $\mathcal{C}$ be a compactly generated pointed $\infty$-category. Then there exists a unital stable $\infty$-operad $\mathcal{O}^\otimes$ with the following properties:

(a) The underlying $\infty$-category of $\text{Sp}(\mathcal{C})^\otimes$ with underlying $\infty$-category $\text{Sp}(\mathcal{C})$.

(b) For each $n \geq 1$, the tensor product functor $\otimes^n : \text{Sp}(\mathcal{C})^n \to \text{Sp}(\mathcal{C})$ is given by the derivative of the Cartesian product functor $\mathcal{C}^n \to \mathcal{C}$.

To bring out the analogy between Conjecture 6.3.0.13 and Proposition 6.3.0.14, let us recall how to describe explicitly the $\partial_n$ where Proposition 6.2.3.15, we see that Proposition 6.3.0.14.

Let $C$ be a compactly generated pointed $\infty$-category, and let $\mathcal{C}^\times$ be the associated Cartesian symmetric monoidal $\infty$-category. Then $\mathcal{C}^\times$ is a differentiable $\infty$-operad, so it admits a stabilization $\mathcal{O}^\otimes$ (Proposition 6.2.4.14). Note that since $\mathcal{C}$ is pointed, the $\infty$-operad $\mathcal{O}^\otimes$ is unital. This proves the following:

**Proposition 6.3.0.14.** Let $\mathcal{C}$ be a compactly generated pointed $\infty$-category. Then there exists a unital stable $\infty$-operad $\mathcal{O}^\otimes$ with the following properties:

(a) The underlying $\infty$-category of $\mathcal{O}^\otimes$ with underlying $\infty$-category $\text{Sp}(\mathcal{C})$.

(b) For each $n \geq 1$, the tensor product functor $\otimes^n : \mathcal{O}^n \to \mathcal{O}$ is equivalent to (the opposite of) the functor $\partial_n(\text{id}_\mathcal{C}) : \text{Sp}(\mathcal{C})^n \to \text{Sp}(\mathcal{C})$.

To bring out the analogy between Conjecture 6.3.0.13 and Proposition 6.3.0.14, let us recall how to describe explicitly the $\mathcal{n}$ derivative $\partial_n(F)$ of a functor $F : \mathcal{C} \to \mathcal{D}$. Combining Remark 6.1.3.23 with Proposition 6.2.3.15, we see that $\partial_n(F)$ can be identified with the (multivariate) derivative $\mathcal{D} \mathcal{C}_n(F)$, where $\mathcal{C}_n(F)$ denotes the $n$th cross effect of $F$. In other words, we have a canonical equivalence

$$\partial_n(F) \simeq \mathcal{D} \mathcal{C}_n(F),$$

where $F^{\mathcal{C}} : \mathcal{C}^n \to \mathcal{D}$ is the functor given by $F^{\mathcal{C}}(C_1, \ldots, C_n) = F(C_1 \times \cdots \times C_n)$. For our purposes, it will be easier to study a dual construction, where we replace coproduts by products and reduction by coreduction.

**Definition 6.3.0.15.** Let $\mathcal{C}$ and $\mathcal{D}$ be compactly generated pointed $\infty$-categories, and let $F : \mathcal{C} \to \mathcal{D}$ be a reduced functor which commutes with filtered colimits. For each integer $n \geq 1$, let $\partial^n(F) : \text{Sp}(\mathcal{C})^n \to \text{Sp}(\mathcal{D})$ denote the functor $\mathcal{D} \mathcal{C}_n(F^{\mathcal{D}})$, where $F^{\mathcal{D}} : \mathcal{C}^n \to \mathcal{D}$ is given by $F^{\mathcal{D}}(C_1, \ldots, C_n) = F(C_1 \times \cdots \times C_n)$. We will refer to $\partial^n(F)$ as the $n$th coderivative of $F$.

**Remark 6.3.0.16.** Our description of $\partial^n(F)$ as $\mathcal{D} \mathcal{C}_n(F^{\mathcal{D}})$ was made to emphasize the analogy with the description of the usual derivative $\partial_n(F)$ as $\mathcal{D} \mathcal{C}_n(F^{\mathcal{D}})$. However, Definition 6.3.0.15 can be simplified: since the canonical map $F^{\mathcal{D}} \to \mathcal{C}_n(F^{\mathcal{D}})$ induces an equivalence of derivatives, we have $\partial^n(F) = \mathcal{D} \mathcal{C}_n(F^{\mathcal{D}})$. This observation renders the study of coderivatives much more tractable than the formally dual theory of derivatives.

We can summarize Proposition 6.3.0.14 informally as follows: for every compactly generated $\infty$-category $\mathcal{C}$, the symmetric sequence of coderivatives $\{\partial^n(\text{id}_\mathcal{C})\}_{n \geq 1}$ can be regarded as a coalgebra object of $\text{SSeq}(\mathcal{O}, \mathcal{O})$. In other words, we can regard Proposition 6.3.0.14 as a dual version of the first part of Conjecture 6.3.0.7. Our goal in this section is to formulate and prove dual versions of the remaining assertions of Conjecture 6.3.0.7:

(2') Let $F : \mathcal{C} \to \mathcal{D}$ be a reduced functor between compactly generated pointed $\infty$-categories which commutes with filtered colimits. Then $\partial^*(F)$ is equipped with compatible left and right (co)actions of the coalgebras $\partial^n(\text{id}_\mathcal{D})$ and $\partial^n(\text{id}_\mathcal{C})$. 
(3’) Let \( F : \mathcal{C} \to \mathcal{D} \) and \( G : \mathcal{D} \to \mathcal{E} \) be reduced functors between compactly generated pointed \( \infty \)-categories which commute with filtered colimits. Then there is a canonical equivalence

\[
\partial^* (G \circ F) \simeq \partial^* (G) \otimes^{\partial^* (\text{id}_\mathcal{D})} \partial^* (F),
\]

where the superscript indicates that the relative tensor product is formed in the opposite \( \infty \)-category: that is, the right hand side is given by the totalization of a cosimplicial object

\[
\partial^* (G) \circ \partial^* (F) \quad \quad \partial^* (G) \circ \partial^* (\text{id}_\mathcal{D}) \circ \partial^* (F) \quad \quad \cdots
\]

in the \( \infty \)-category \( \text{SSeq} (\text{Sp} (\mathcal{C}), \text{Sp} (\mathcal{E})) \).

The proof of (2’) is essentially already contained in §6.2: in §6.3.1, we will construct the relevant structures on \( \partial^* (F) \) can be obtained by applying the stabilization construction of §6.2.5 to a suitable correspondence between \( \infty \)-operads. In §6.3.2 we will give a precise formulation of (3’) by constructing a map

\[
\partial^* (G \circ F) \to \partial^* (G) \otimes^{\partial^* (\text{id}_\mathcal{D})} \partial^* (F).
\]

The hard part is to show that this map is an equivalence, which we prove in §6.3.6 (see Theorem 6.3.2.1). Our strategy is to use the formula \( \partial^n (F) \simeq \partial (F^\times) \) of Remark 6.3.0.16 to reduce to the chain rule for first derivatives (Theorem 6.2.1.22). The main obstacle is that Theorem 6.2.1.22 applies only to functors which are reduced in each variable. In §6.3.5, we will explain how to circumvent this difficulty by introducing suitable “correction terms” into the formula for the chain rule. The main ingredient is a certain technical result concerning the commutation of differentiation with limits (Theorem 6.3.3.14), which we prove in §6.3.4.

This result can be regarded as a relative version of Arone-Mahowald calculation of the derivatives of the identity functor on the \( \infty \)-category of pointed spaces, which we review in §6.3.3.

**Remark 6.3.0.17.** Let \( \mathcal{C} \) be a compactly generated pointed \( \infty \)-category. The relationship between the symmetric sequences \( \partial^* (\text{id}_\mathcal{C}) \) and \( \partial_* (\text{id}_\mathcal{C}) \) is more than just an analogy: they are Koszul dual to one another. Given a suitable theory of Koszul duality, one can deduce Conjecture 6.3.0.13 from Proposition 6.3.0.14, and the remaining assertions of Conjecture 6.3.0.7 from the versions of (2’) and (3’) that we prove in this section. We plan to return to the subject in a future work.

### 6.3.1 Cartesian Structures

Let \( \mathcal{C} \) be a compactly generated pointed \( \infty \)-category. According to Proposition 6.3.0.14, the symmetric sequence of coderivatives \( \{ \partial^n (\text{id}_\mathcal{C}) \}_{n \geq 1} \) is equipped with a coherently associative comultiplication, encoded by a (unital) stable \( \infty \)-operad \( \text{Sp} (\mathcal{C})^\otimes \) with underlying \( \infty \)-category \( \text{Sp} (\mathcal{C}) \). The \( \infty \)-operad \( \text{Sp} (\mathcal{C})^\otimes \) was constructed in §6.2.4 by stabilizing the Cartesian symmetric monoidal \( \infty \)-category \( \mathcal{C}_\times \).

Now suppose that \( F : \mathcal{C} \to \mathcal{D} \) is a reduced functor between compactly generated pointed \( \infty \)-categories. Our goal in this section is to show that the symmetric sequence \( \{ \partial^n (F) \}_{n \geq 1} \) is equipped with (compatible) left and right (co)actions of \( \{ \partial^n (\text{id}_\mathcal{D}) \}_{n \geq 1} \) and \( \{ \partial^n (\text{id}_\mathcal{C}) \}_{n \geq 1} \), respectively. We first explain how to encode these actions using the language of (families of) \( \infty \)-operads.

**Definition 6.3.1.1.** A correspondence of \( \infty \)-operads is \( \Delta^1 \)-family of \( \infty \)-operads \( p : \mathcal{O}^\otimes \to \Delta^1 \times \text{N}(\mathcal{F}\text{in}_n) \). We will say that \( \mathcal{O}^\otimes \) is a correspondence from the \( \infty \)-operad \( \mathcal{O}^\otimes_0 = \{ 0 \} \times \Delta^1 \mathcal{O}^\otimes \) to the \( \infty \)-operad \( \mathcal{O}^\otimes_1 = \{ 1 \} \times \Delta^1 \mathcal{O}^\otimes \). We will say that a correspondence of \( \infty \)-operads \( p \) is corepresentable (stable, differentiable) it is corepresentable (stable, differentiable) when regarded as a (local) \( \Delta^1 \)-family of \( \infty \)-operads.

Let \( p : \mathcal{O}^\otimes_0 \times \Delta^1 \times \text{N}(\mathcal{F}\text{in}_n) \) be a corepresentable correspondence from an \( \infty \)-operad \( \mathcal{O}^\otimes_0 \) to an \( \infty \)-operad \( \mathcal{O}^\otimes_1 \). For each \( n \geq 0 \), the unique active morphism \( (n) \to (1) \) determines a map from \( (0, (n)) \) to \( (1, (1)) \) in \( \Delta^1 \times \text{N}(\mathcal{F}\text{in}_n) \), to which we can associate a functor

\[
F^n : \mathcal{O}^\otimes_0 \simeq \mathcal{O}^\otimes_{(0, (n))} \to \mathcal{O}^\otimes_{(1, (1))} \simeq \mathcal{O}^\otimes_1.
\]
Each $F^n$ is equivariant with respect to the action of the symmetric group $\Sigma_n$ on $O^n_0$; we may therefore think of this construction as giving a family of functors $F^I : O^n_0 \to O_1$ for every nonempty finite set $I$. If $O^\otimes$ is a stable correspondence of $\infty$-operads, then each of the functors $F^I$ is exact in each variable, so that we can view $\{F^n\}_{n \geq 1}$ as a symmetric sequence of functors from $O_0$ to $O_1$. We will denote this symmetric sequence by $F^\ast$.

Since $O^n_0$ and $O^n_1$ are corepresentable $\infty$-operads, Remark 6.2.4.4 supplies tensor product functors

$$\otimes^I_0 : O^n_0 \to O_0 \quad \otimes^I_1 : O^n_1 \to O_1$$

for every nonempty finite set $I$. If $E$ is an equivalence relation on $I$, we have canonical natural transformations

$$\otimes^{I/E}_1 \circ \prod_{J \in I/E} F^J \leftarrow F^I \to \otimes^{I/E}_1 \circ \prod_{J \in I/E} \otimes^J,$$

If we suppose that $p$ is a stable correspondence of $\infty$-operads, then we can combine these maps as $E$ varies over $\text{Equiv}(I)$, to obtain maps

$$\bigoplus_{E \in \text{Equiv}(I)} \otimes^{I/E}_1 \circ \prod_{J \in I/E} F^J \leftarrow F^I \to \bigoplus_{E \in \text{Equiv}(I)} \otimes^{I/E}_1 \circ \prod_{J \in I/E} \otimes^J.$$

Allowing $I$ to vary, we obtain maps of symmetric sequences

$$F^\ast \to F^\ast \circ \otimes^I_0 \quad F^\ast \to \otimes^I_1 \circ F^\ast.$$

**Remark 6.3.1.2.** Let $O_0^\otimes$ and $O_1^\otimes$ be reduced stable $\infty$-operads, corresponding (under the dictionary of Remark 6.3.0.10) to associative coalgebra objects $\otimes^I_0$ and $\otimes^I_1$ of $\text{SSeq}(O_0, O_0)$ and $\text{SSeq}(O_1, O_1)$, respectively.

(a) Symmetric sequences $F^\ast \in \text{SSeq}(O_0, O_1)$ which are equipped with (compatible) left coactions of $\otimes^I_1$ and right coactions of $\otimes^I_0$.

(b) Stable correspondences $O^\otimes$ from $O_0^\otimes$ to $O_1^\otimes$ which are *unital* in the sense that the initial object of $O_0^\otimes$ is also an initial object of $O_1^\otimes$.

As in Remark 6.3.0.10, we will be content to view this as a heuristic principle: we will not attempt to give a proof (or even a precise formulation) in this book.

Motivated by this analysis, we formulate the following dual version of assertion (2) of Conjecture 6.3.0.7:

**Proposition 6.3.1.3.** Let $\mathcal{C}$ and $\mathcal{D}$ be compactly generated pointed $\infty$-categories, and let $F : \mathcal{C} \to \mathcal{D}$ be a reduced functor which preserves filtered colimits. Then there exists a stable correspondence of $\infty$-operads $q : O^\otimes \to \Delta^1 \times N(\mathcal{F}\text{in}_n)$ with the following properties:

1. The underlying stable $\infty$-operads $O_0^\otimes$ and $O_1^\otimes$ are given by $\text{Sp}(\mathcal{C})^\otimes$ and $\text{Sp}(\mathcal{D})^\otimes$, respectively (where $\text{Sp}(\mathcal{C})^\otimes$ and $\text{Sp}(\mathcal{D})^\otimes$ are as in Proposition 6.3.0.14).

2. For each $n \geq 1$, the functor $\text{Sp}(\mathcal{C})^n \to \text{Sp}(\mathcal{D})$ determined by $q$ is equivalent to the coderivative $\partial^n(F)$.

Our construction of the correspondence $O^\otimes \to \Delta^1 \times N(\mathcal{F}\text{in}_n)$ of Proposition 6.3.1.3 will proceed in three steps:

(a) First, take $p : \mathcal{M} \to \Delta^1$ be a correspondence of $\infty$-categories associated to the functor $F$. That is, $p$ is a coCartesian fibration with fibers $\mathcal{C} \simeq \mathcal{M}_0 = \mathcal{M} \times_{\Delta^1} \{0\}$ and $\mathcal{D} \simeq \mathcal{M}_1 = \mathcal{M} \times_{\Delta^1} \{1\}$, and the induced map from $\mathcal{M}_0$ to $\mathcal{M}_1$ is given by $F$.

(b) We will show that the correspondence $\mathcal{M}$ from $\mathcal{C}$ to $\mathcal{D}$ determines a correspondence of $\infty$-operads $\mathcal{M}^\otimes$ from $\mathcal{C}^\otimes$ to $\mathcal{D}^\otimes$, using a relative version of Construction 2.4.1.4.
(c) By applying the stabilization construction described in §6.2.5 to \( M^\times \), we will obtain a stable correspondence from \( \text{Sp}(\mathcal{C})^\circ \) to \( \text{Sp}(\mathcal{D})^\circ \).

We will devote most of this section to carrying out step \((b)\). We begin with a relative version of Definition 2.4.0.1.

**Definition 6.3.1.4.** Let \( S \) be a simplicial set and let \( q : \mathcal{O}^\circ \to S \times N(\text{Fin}_\ast) \) be a map of simplicial sets. We will say that \( q \) is a Cartesian local \( S \)-family of \( \infty \)-operads if it satisfies the following conditions:

1. The map \( q \) is a corepresentable local \( S \)-family of \( \infty \)-operads.
2. For each \( s \in S \), the induced map \( q_s : \mathcal{C}_s^\circ \to N(\text{Fin}_\ast) \) is a coCartesian fibration which determines a Cartesian symmetric monoidal structure on the \( \infty \)-category \( \mathcal{C}_s \) (see Definition 2.4.0.1).
3. For every \( s \in S \), the inclusion \( \mathcal{O}_{s,S}^\circ \hookrightarrow \mathcal{O}^\circ \) carries \( q_s \)-coCartesian edges to \( q \)-coCartesian edges.

**Remark 6.3.1.5.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories which admit finite products, and let \( q : \mathcal{O}^\circ \to \Delta^1 \times N(\text{Fin}_\ast) \) be a corepresentable correspondence between the symmetric monoidal \( \infty \)-categories \( \mathcal{O}_0^\circ = \mathcal{C}^\times \) and \( \mathcal{O}_1^\circ = \mathcal{D}^\times \). For each \( n \geq 0 \), restricting \( q \) to the active morphism \( \alpha : (0, \langle n \rangle) \to (1, \langle 1 \rangle) \) of \( \Delta^1 \times N(\text{Fin}_\ast) \) gives a functor \( F^n : \mathcal{O}^\circ \to \mathcal{D} \). Note that \( \alpha \) factors as a composition \((0, \langle 1 \rangle) \to (0, \langle 1 \rangle) \to (1, \langle 1 \rangle)\). For every \( n \)-tuple of objects \( C_1, \ldots, C_n \in \mathcal{C} \), this factorization determines a map

\[
F^n(C_1, \ldots, C_n) \to F^1(C_1 \times \cdots \times C_n).
\]

Condition (3) of Definition 6.3.1.4 guarantees that these maps is an equivalences: that is, we can recover each of functors \( F^n : \mathcal{C}^\circ \to \mathcal{D} \) by composing the single functor \( F^1 : \mathcal{C} \to \mathcal{D} \) with the Cartesian product on \( \mathcal{C} \).

The analysis given in Remark 6.3.1.5 suggests that Cartesian local \( S \)-family of \( \infty \)-operads should be determined by the underlying locally coCartesian fibration

\[
\mathcal{O} \simeq \mathcal{O}^\circ \times_{N(\text{Fin}_\ast)}\{\langle 1 \rangle\} \to S.
\]

We can formulate this more precisely as follows:

**Theorem 6.3.1.6.** Let \( \mathcal{C} \to S \) be a locally coCartesian fibration of simplicial sets. Then there exists a Cartesian local \( S \)-family of \( \infty \)-operads \( \mathcal{C}^\times \to S \times N(\text{Fin}_\ast) \) with \( \mathcal{C} \simeq \mathcal{C}^\times \times N(\text{Fin}_\ast)\{\langle 1 \rangle\} \). Moreover, \( \mathcal{C}^\times \) is determined uniquely up to equivalence.

**Proof of Proposition 6.3.1.3.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a reduced functor between compactly generated pointed \( \infty \)-categories which preserves filtered limits, and let \( M \to \Delta^1 \) be a correspondence from \( \mathcal{C} \) to \( \mathcal{D} \) associated to \( F \). According to Theorem 6.3.1.6, we can extend \( M \) to a Cartesian \( \Delta^1 \)-family of \( \infty \)-operads \( q : M^\times \to \Delta^1 \times N(\text{Fin}_\ast) \). Then \( q \) is a differentiable local \( S \)-family of \( \infty \)-operads; let \( \mathcal{O}^\circ \to \Delta^1 \times N(\text{Fin}_\ast) \) denote the stable \( \Delta^1 \)-family of \( \infty \)-operads obtained by applying Construction 6.2.5.20. Then \( \mathcal{O}^\circ \) is a stable correspondence from \( \text{Sp}(\mathcal{C})^\circ \) to \( \text{Sp}(\mathcal{D})^\circ \). The identification of the induced functors \( \text{Sp}(\mathcal{C})^\times \to \text{Sp}(\mathcal{D}) \) with \( \partial^n(F) \) follows from Remark 6.3.1.5.

Theorem 6.3.1.6 is an immediate consequence of a more precise result (Theorem 6.3.1.15), which we will prove at the end of this section. First, we need to formulate a generalization of Definition 2.4.1.1.

**Definition 6.3.1.7.** Let \( q : \mathcal{O}^\circ \to S \times N(\text{Fin}_\ast) \) be a corepresentable local \( S \)-family of \( \infty \)-operads, and let \( p : \mathcal{D} \to S \) be a locally coCartesian fibration. We will say that a functor \( \pi \in \text{Fun}_S(\mathcal{O}^\circ, \mathcal{D}) \) is a weak Cartesian structure on \( \mathcal{O}^\circ \) if it satisfies the following conditions:

1. For each \( s \in S \), the fiber \( \mathcal{O}^\circ_s \) is a symmetric monoidal \( \infty \)-category and the induced map \( \pi_s : \mathcal{O}^\circ_s \to \mathcal{D}_s \) is a weak Cartesian structure on the symmetric monoidal \( \infty \)-category \( \mathcal{O}^\circ_s \) (see Definition 2.4.1.1).
(2) Let $e$ be a locally $q$-coCartesian edge of $\mathcal{C}^\otimes$ lying over the unique active morphism $\langle n \rangle \to \langle 1 \rangle$ in $N(\mathcal{F}_{\mathbb{N}})$.

Then $p(e)$ is a locally $p$-coCartesian edge of $\mathcal{D}$.

We say that $\pi$ is a Cartesiian structure if it is a weak Cartesian structure which induces an equivalence of $\infty$-categories $\mathcal{C}_s \to \mathcal{D}_s$ for each vertex $s \in S$.

Lemma 6.3.1.8. Let $S$ be a simplicial set and let $q : \mathcal{C}^\otimes \to S \times N(\mathcal{F}_{\mathbb{N}})$ be a corepresentable local $S$-family of $\infty$-operads. If $q$ admits a Cartesian structure, then it is a Cartesian $S$-family of $\infty$-operads.

Proof. It suffices to prove that each pullback $\mathcal{C}^\otimes \times_S \Delta^n$ is a corepresentable $\Delta^n$-family of $\infty$-operads for every map $\Delta^n \to S$. We may therefore assume without loss of generality that $S$ is an $\infty$-category. The only nontrivial point is to verify condition (3) of Definition 6.3.1.4. Let $f : X \to Y$ be a $q_s$-coCartesian morphism in $\mathcal{C}^\otimes$: we wish to show that $f$ is $q$-coCartesian. According to Lemma T.2.4.2.7, it will suffice to show that for every locally $q$-coCartesian morphism $g : Y \to Z$, the composition $g \circ f$ is locally $q$-coCartesian. Using Remark 6.2.5.4, we can reduce to the case where $Z \in \mathcal{C} = \mathcal{C}^\otimes_{(1)}$. The map $g$ factors as a composition

$$Y \xrightarrow{g'} Y' \xrightarrow{g''} Z,$$

where $g'$ is inert (and therefore $q$-coCartesian) and $g''$ is active. Since $g$ is locally $q$-coCartesian, Lemma T.2.4.2.7 implies that $g''$ is locally $q$-coCartesian. We may replace $Y$ by $Y'$ and thereby reduce to the case where the image of $g$ in $N(\mathcal{F}_{\mathbb{N}})$ is active. Factor $f$ as a composition $f'' \circ f'$, where $f'$ is inert and $f''$ is active. Lemma T.2.4.2.7 implies that $g \circ f$ is locally $q$-coCartesian if and only if $g \circ f''$ is locally $q$-coCartesian. We may therefore replace $f$ by $f''$ and thereby reduce to the case where $f$ is active. Let $s$ denote the image of $Z$ in $S$, and factor $g \circ f$ as a composition

$$X \xrightarrow{h'} Z' \xrightarrow{h''} Z,$$

where $h'$ is locally $q$-coCartesian and $h''$ is a morphism in $\mathcal{C}_s$. We wish to prove that $h''$ is an equivalence.

Let $p : \mathcal{D} \to S$ be a locally coCartesian fibration and let $\pi : \mathcal{C}^\otimes \to \mathcal{D}$ be a Cartesian structure on $\mathcal{C}^\otimes$. Let $t \in S$ denote the image of $Z$. Then $\pi$ induces an equivalence $\mathcal{C}_t \to \mathcal{D}_t$ (by condition (1) of Definition 6.3.1.7). It will therefore suffice to show that $\pi(h'')$ is an equivalence in $\mathcal{D}_t$. Since $\pi(h')$ is locally $p$-coCartesian (condition (2) of Definition 6.3.1.7), we are reduced to proving that $\pi(h) = \pi(g) \circ \pi(f)$ is locally $q$-coCartesian. Because $f$ is an active $q_s$-coCartesian morphism in $\mathcal{C}^\otimes_s$, the map $\pi(f)$ is an equivalence in $\mathcal{C}_s$ (by condition (1) of Definition 6.3.1.7). We are therefore reduced to proving that $\pi(g)$ is locally $q$-coCartesian, which follows from immediately from condition (2) of Definition 6.3.1.7.

Proposition 6.3.1.9. Let $p : \mathcal{C}^\otimes \to S \times N(\mathcal{F}_{\mathbb{N}})$ be a Cartesian local $S$-family of $\infty$-operads, let $q : \mathcal{D} \to S$ be a locally coCartesian fibration such that each fiber $\mathcal{D}_s$ admit finite products. Let $\text{Fun}_S^\otimes(\mathcal{C}^\otimes, \mathcal{D})$ denote the full subcategory of $\text{Fun}_S(\mathcal{C}^\otimes, \mathcal{D})$ spanned by the weak Cartesian structures and let $\text{Fun}_S^\otimes(\mathcal{C}, \mathcal{D})$ be the full subcategory of $\text{Fun}_S(\mathcal{C}, \mathcal{D})$ spanned by those maps $F : \mathcal{C} \to \mathcal{D}$ satisfying the following conditions:

(a) The functor $F$ carries locally $p$-coCartesian edges to locally $q$-coCartesian edges.

(b) For each vertex $s \in S$, the induced map $\mathcal{C}_s \to \mathcal{D}_s$ preserves finite products.

Then the restriction map $\text{Fun}_S^\otimes(\mathcal{C}^\otimes, \mathcal{D}) \to \text{Fun}_S^\otimes(\mathcal{C}, \mathcal{D})$ is an equivalence of $\infty$-categories.

Proof. For every map of simplicial sets $T \to S$, let $\mathcal{C}^\otimes_T = T \times_S \mathcal{C}^\otimes$ and $\mathcal{C}_T = T \times_S \mathcal{C}$. Let $\text{Fun}_S^\otimes(\mathcal{C}^\otimes_T, \mathcal{D})$ denote the full subcategory of $\text{Fun}_S(\mathcal{C}^\otimes_T, \mathcal{D})$ spanned by those functors which determine weak Cartesian structures $\mathcal{C}^\otimes_T \to T \times_S \mathcal{D}$, and define $\text{Fun}_S^\otimes(\mathcal{C}_T, \mathcal{D}) \subseteq \text{Fun}_S(\mathcal{C}_T, \mathcal{D})$ similarly. We will prove that each restriction map $\theta_T : \text{Fun}_S^\otimes(\mathcal{C}^\otimes_T, \mathcal{D}) \to \text{Fun}_S^\otimes(\mathcal{C}_T, \mathcal{D})$ is an equivalence of $\infty$-categories. The construction $T \mapsto \theta_T$ carries homotopy colimits to homotopy limits. We may therefore reduce to the case where $T$ is a simplex. Replacing $S$ by $T$, we may assume that $S = \Delta^k$ for some integer $k \geq 0$.

We define a subcategory $\mathcal{J} \subseteq S \times \mathcal{F}_{\mathbb{N}} \times [1]$ as follows:

(a) Every object of $S \times \mathcal{F}_{\mathbb{N}} \times [1]$ belongs to $\mathcal{J}$.
6.3. THE CHAIN RULE

(b) A morphism \((s, \langle n \rangle, i) \to (s', \langle n' \rangle, i')\) in \(\mathcal{F}\text{in}_a \times [1]\) belongs to \(J\) if and only if either \(i' = 1\) or the induced map \(\alpha : \langle n \rangle \to \langle n' \rangle\) is active.

Let \(\mathcal{C}'\) denote the fiber product \(\mathcal{C}^\otimes \times_{\mathcal{S} \times N(\mathcal{F}\text{in}_a)} N(\mathcal{J})\), which we regard as a subcategory of \(\mathcal{C}^\otimes \times \Delta^1\), and let \(\mathcal{C}' : \mathcal{C}' \to N(\mathcal{J})\) denote the projection. Let \(\mathcal{C}_0'\) and \(\mathcal{C}'_1\) denote the intersections of \(\mathcal{C}'\) with \(\mathcal{C}^\otimes \times \{0\}\) and \(\mathcal{C}^\otimes \times \{1\}\), respectively. We note that there is a canonical isomorphism \(\mathcal{C}_1' \simeq \mathcal{C}^\otimes\).

Let \(\mathcal{E}\) denote the full subcategory of \(\text{Fun}_S(\mathcal{C}', \mathcal{D})\) spanned by those functors \(F\) which satisfy the following conditions:

(i) For every object \(C \in \mathcal{C}^\otimes\), the induced map \(F(C, 0) \to F(C, 1)\) is an equivalence in \(\mathcal{D}\).

(ii) The restriction \(F|_{\mathcal{C}'_1}\) is a weak Cartesian structure on \(\mathcal{C}^\otimes\).

It is clear that if (i) and (ii) are satisfied, then the restriction \(F_0 = F|_{\mathcal{C}_0'}\) satisfies the following additional conditions:

(iii) For each \(s \in \mathcal{S}\), the restriction \(F_0|_{\mathcal{E}_s}\) is a functor from \(\mathcal{E}_s\) to \(\mathcal{D}_s\) which preserves finite products.

(iv) Let \(s \in \mathcal{S}\), and let \(\alpha\) be an active locally \(p\)-coCartesian morphism in \(\mathcal{C}_s^\otimes\). Then \(F_0(\alpha)\) is an equivalence in \(\mathcal{D}\).

(v) Let \(\alpha\) be a locally \(p\)-coCartesian morphism in \(\mathcal{E}\). Then \(F_0(\alpha)\) is a locally \(q\)-coCartesian morphism in \(\mathcal{D}\).

Condition (i) is equivalent to the assertion that \(F\) is a right Kan extension of \(F|_{\mathcal{C}'_1}\). Proposition T.4.3.2.15 implies that the restriction map \(r : \mathcal{E} \to \text{Fun}_S^\otimes(\mathcal{C}^\otimes, \mathcal{D})\) induces a trivial Kan fibration onto its essential image. The map \(r\) has a section \(s\), given by composition with the projection map \(\mathcal{C}' \to \mathcal{C}^\otimes\). The restriction map \(\text{Fun}_S^\otimes(\mathcal{C}^\otimes, \mathcal{D}) \to \text{Fun}_S^\otimes(\mathcal{E}, \mathcal{D})\) factors as a composition

\[
\text{Fun}_S^\otimes(\mathcal{C}^\otimes, \mathcal{D}) \xrightarrow{e} \mathcal{E} \xrightarrow{\mathcal{E} \to \text{Fun}_S^\otimes(\mathcal{E}, \mathcal{D})},
\]

where \(e\) is induced by composition with the inclusion \(\mathcal{C} \subseteq \mathcal{C}_s \subseteq \mathcal{C}'\). Consequently, it will suffice to prove that \(e\) is an equivalence of \(\otimes\)-categories.

Let \(\mathcal{E}_0 \subseteq \text{Fun}(\mathcal{C}'_0, \mathcal{D})\) be the full subcategory spanned by those functors which satisfy conditions (iii), (iv), and (v). The map \(e\) factors as a composition

\[
\mathcal{E} \xrightarrow{\mathcal{E} \to \mathcal{E}_0} \mathcal{E}_0 \xrightarrow{\mathcal{E}_0 \to \text{Fun}_S^\otimes(\mathcal{E}, \mathcal{D})}.
\]

We will complete the proof by showing that that \(\mathcal{E}'\) and \(\mathcal{E}''\) are trivial Kan fibrations.

Let \(f : \mathcal{E}'_0 \to \mathcal{D}\) be an arbitrary functor, and let \(C \in \mathcal{C}'_0 \subseteq \mathcal{C}'\). There exists a unique \(\alpha : (j, \langle n \rangle, 0) \to (j, \langle 1 \rangle, 0)\) in \(J\); choose a locally \(p\)-coCartesian morphism \(\overline{\alpha} : C \to C'\) lifting \(\alpha\). Since \(\mathcal{C}^\otimes\) is Cartesiann \(\mathcal{S}\)-family of \(\otimes\)-operads, the morphism \(\overline{\alpha}\) is \(p\)-coCartesian. It follows that \(\overline{\alpha}\) exhibits \(C'\) as an initial object of \(\mathcal{C} \times (\mathcal{C}'_0/\mathcal{C} \times \mathcal{E}_0)\). Consequently, \(f\) is a right Kan extension of \(f|_{\mathcal{C}'}\) at \(C\) if and only if \(f(\overline{\alpha})\) is an equivalence. It follows that \(f\) satisfies (iv) if and only if \(f\) is a right Kan extension of \(f|_{\mathcal{C}_s}\). The same argument (and Lemma T.4.3.2.7) shows that every functor \(f_0 : \mathcal{C} \to \mathcal{D}\) admits a right Kan extension to \(\mathcal{C}'_0\).

Applying Proposition T.4.3.2.15, we deduce that \(\mathcal{E}''\) is a trivial Kan fibration.

It remains to show that \(\mathcal{E}'\) is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to prove the following pair of assertions, for every functor \(f \in \mathcal{E}_0\):

(1) There exist a functor \(F : \mathcal{E}' \to \mathcal{D}\) which is a left Kan extension of \(f = F|_{\mathcal{E}_0}\).

(2) Let \(F : \mathcal{E}' \to \mathcal{D}\) be an arbitrary extension of \(f\). Then \(F\) is a left Kan extension of \(f\) if and only if \(F\) belongs to \(\mathcal{E}\).
For every finite linearly ordered set \( J \), let \( J^+ \) denote the disjoint union \( J \coprod \{ \infty \} \), where \( \infty \) is a new element larger than every element of \( J \). Let \((C, 1) \in \mathcal{C}_{J_s}^0 \times \{1\} \subseteq \mathcal{C}^s\) lying over a vertex \( s \in S \). Since there exists a final object \( 1_s \in \mathcal{C}_s \), the \( \infty \)-category \( \mathcal{C}_{J_s}^0 \times \mathcal{C}_{J_s}^s \) also has a final object, given by the map \( \alpha : (C', 0) \to (C, 1) \), where \( C' \in \mathcal{C}_{J'_s}^\infty \) corresponds, under the equivalence

\[
\mathcal{C}_{s,J_s}^\infty \simeq \mathcal{C}_s \times \mathcal{C}_{s,J_s}^s,
\]
to the pair \( (1_s, C) \). We now apply Lemma T.4.3.2.13 to deduce (1), together with the following analogue of (2):

\( (2') \) An arbitrary functor \( F : \mathcal{C} \to \mathcal{D} \) which extends \( f \) is a left Kan extension of \( f \) if and only if, for every morphism \( \alpha : (C', 0) \to (C, 1) \) as above, the induced map \( F(C', 0) \to F(C, 1) \) is an equivalence in \( \mathcal{D} \).

To complete the proof, it will suffice to show that \( F \) satisfies the conditions stated in (2') if and only if \( F \in \mathcal{E} \). We first prove the “if” direction. Suppose that \( F \in \mathcal{E} \) and let \( \alpha : (C', 0) \to (C, 1) \) be as above; we wish to prove that \( F(\alpha) : F(C', 0) \to F(C, 1) \) is an equivalence in \( \mathcal{D} \). The map \( \alpha \) factors as a composition

\[
(C', 0) \xrightarrow{\beta'} (C', 1) \xrightarrow{\alpha''} (C, 1).
\]

Condition (i) guarantees that \( F(\alpha') \) is an equivalence. Condition (ii) guarantees that \( F(C', 1) \) is equivalent (as an object of \( \mathcal{D}_s \)) to a product \( F(1_s, 1) \times F(C, 1) \), and that \( F(\alpha'') \) can be identified with the projection onto the second factor. Moreover, since \( 1_s \) is a final object of \( \mathcal{C}_s \), condition (ii) also guarantees that \( F(1_s, 1) \) is a final object of \( \mathcal{D}_s \). It follows that \( F(\alpha'') \) is an equivalence, so that \( F(\alpha) \) is an equivalence as desired.

Now let us suppose that \( F \) satisfies the condition of (2'). We wish to prove that \( F \in \mathcal{E} \). We begin by verifying condition (i). Let \( C \in \mathcal{C}_{s,J_s}^\infty \) for some finite linearly ordered set \( J \), lying over a vertex \( s \in S \). Let \( \alpha : (C', 0) \to (C, 1) \) be defined as above. Let \( \beta : (J_s, 0) \to (J'_s, 0) \) be the morphism in \( \mathcal{J} \) induced by the inclusion \( J \subseteq J^+ \). Choose a locally \( p' \)-coCartesian morphism \( \beta : (C, 0) \to (C'', 0) \) lifting \( \beta \). Since the symmetric monoidal structure on \( \mathcal{C}_s \) is Cartesian, the final object \( 1_s \in \mathcal{C}_s \) is also the unit object of \( \mathcal{C} \) and we can identify \( C'' \) with \( C' \). The composition \( (C, 0) \xrightarrow{\beta} (C', 1) \xrightarrow{\alpha''} (C, 1) \) is homotopic to the canonical map \( \gamma : (C, 0) \to (C, 1) \) appearing in the statement of (i). Condition (iv) guarantees that \( F(\beta) \) is an equivalence, and (2') guarantees that \( F(\alpha) \) is an equivalence. Using the two-out-of-three property, we deduce that \( F(\gamma) \) is an equivalence, so that \( F \) satisfies (i).

Let \( F_1 = F|_{\mathcal{C}_{J_s}^s} \), so that we can regard \( F_1 \) as a functor \( \mathcal{C}_{J_s}^s \to \mathcal{D} \). To prove that \( F \) satisfies (ii), we must verify three conditions:

\( (ii_0) \) If \( s \in S \) and \( \beta \) is an active \( p_s \)-coCartesian morphism of \( \mathcal{C}_{J_s}^s \), then \( F_1(\beta) \) is an equivalence.

\( (ii_1) \) Let \( C \in \mathcal{C}_{s,J_s}^s \) and choose inert morphisms \( \gamma_i : C \to C_i \) in \( \mathcal{C}_{s,J_s}^s \) covering the maps \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) for \( 1 \leq i \leq n \). Then the morphisms \( \gamma_i \) exhibit \( F_1(C) \) as a product \( \prod_{1\leq i \leq n} F_1(C_i) \) in the \( \infty \)-category \( \mathcal{D}_s \).

\( (ii_2) \) Let \( \beta \) be a locally \( p \)-coCartesian morphism in \( \mathcal{C}_s^\infty \) covering the unique active morphism \( \langle n \rangle \to \langle 1 \rangle \) in \( \mathcal{J}_{\mathcal{F}_n} \). Then \( F_1(\beta) \) is a locally \( q \)-coCartesian morphism in \( \mathcal{C}_s^\infty \).

Condition \( (ii_0) \) follows immediately from (i) and (iv). To prove \( (ii_1) \), we consider the maps \( \alpha : (C', 0) \to (C, 1) \) and \( \alpha_i : (C_i', 0) \to (C_i, 1) \) which appear in the statement of (2'). For each \( 1 \leq i \leq n \), we have a commutative diagram

\[
\begin{array}{ccc}
(C', 0) & \xrightarrow{\alpha} & (C, 1) \\
\downarrow{\gamma_i} & & \downarrow{\gamma} \\
(C_i', 0) & \xrightarrow{\alpha_i} & (C_i, 1).
\end{array}
\]
6.3. THE CHAIN RULE

Condition (2') guarantees that the maps \( F(\alpha) \) and \( F(\alpha_i) \) are equivalences in \( \mathcal{D} \). Consequently, it will suffice to show that the maps \( f(\gamma_j') \) exhibit \( f(C',0) \) as a product \( \prod_{j \in J} f(C'_j,0) \) in \( \mathcal{D} \). Let \( f_0 = f|\mathcal{C} \). Using condition (iv), we obtain canonical equivalences

\[
f(C',0) \simeq f_0(1_s \otimes \otimes_{1 \leq i \leq n} C_i) \quad f(C'_i,0) \simeq f_0(1_s \otimes C_i)
\]

Since condition (iii) guarantees that \( f_0 \) preserves products, it will suffice to show that the canonical map

\[
1_s \otimes (\otimes_{1 \leq i \leq n} C_i) \to \otimes_{1 \leq i \leq n} (1_s \otimes C_j)
\]

is an equivalence in the \( \infty \)-category \( \mathcal{C}_s \). This follows easily from our assumption that the symmetric monoidal structure on \( \mathcal{C} \) is Cartesian.

It remains to prove (ii_2). Let \( C \in \mathcal{C}^\otimes_s(n) \) and let \( \beta : C \to D \) be a locally \( p \)-coCartesian morphism in \( \mathcal{C}^\otimes \) covering the unique active map \( \beta_0 : \langle n \rangle \to \langle 1 \rangle \). Choose a \( p \)-coCartesian morphism \( \beta' : C \to C' \) in \( \mathcal{C}^\otimes_s \) lying over \( \beta_0 \). Since \( \mathcal{C}^\otimes_s \) is a Cartesian \( S \)-family of \( \infty \)-operads, the morphism \( \beta' \) is \( p \)-coCartesian. We can therefore factor \( \beta \) as a composition

\[
C \xrightarrow{\beta'} C' \xrightarrow{\beta''} D,
\]

where \( \beta'' \) is a morphism in \( \mathcal{C} \). Since \( \beta \) is locally \( p \)-coCartesian and \( \beta' \) is \( p \)-coCartesian, the morphism \( \beta'' \) is also locally \( p \)-coCartesian. Since \( F_1(\beta') \) is an equivalence (by (ii_0)), it will suffice to show that \( F_1(\beta'') \) is locally \( q \)-coCartesian. We have a commutative diagram

\[
\begin{array}{ccc}
F(C',0) & \longrightarrow & F(C',1) \\
\downarrow f(\beta'') & & \downarrow F_1(\beta'') \\
F(D,0) & \longrightarrow & F(D,1)
\end{array}
\]

Since \( F \) satisfies (i), the horizontal maps in this diagram are equivalences. We are therefore reduced to proving that \( f(\beta'') \) is locally \( q \)-coCartesian, which follows from (iv).

It follows from Proposition 6.3.1.12 that if \( \mathcal{O}^\otimes \to S \times N(\mathcal{F} \text{in}_*) \) is a Cartesian local \( S \)-family of \( \infty \)-operads which admits a Cartesian structure, then \( \mathcal{O}^\otimes \) is determined up to equivalence by the underlying locally Cartesian fibration \( \mathcal{O} \to S \). We next prove a converse: given a locally coCartesian fibration \( \mathcal{O} \to S \) where each fiber \( O \) admits finite products, we construct a local \( S \)-family of \( \infty \)-operads \( \mathcal{O}^\otimes \to S \times N(\mathcal{F} \text{in}_*) \) and a Cartesian structure \( \mathcal{O}^\otimes \to \mathcal{O} \). For this, we need a relative version of Construction 2.4.1.4.

Construction 6.3.1.10. Let \( \Gamma^\times \) be the category introduced in Notation 2.4.1.2 (so that the objects of \( \Gamma^\times \) are pairs \( (\langle n \rangle,K) \), where \( K \subseteq \langle n \rangle^\circ \)). Let \( p : \mathcal{C} \to S \) be a locally coCartesian fibration of simplicial sets. We define a simplicial set \( \tilde{\mathcal{C}}^\times \) equipped with a map \( \tilde{\mathcal{C}}^\times \to S \times N(\mathcal{F} \text{in}_*) \) by the following universal property: for every map of simplicial sets \( K \to N(\mathcal{F} \text{in}_*) \), we have an isomorphism

\[
\text{Fun}_{S \times N(\mathcal{F} \text{in}_*)}(K,\tilde{\mathcal{C}}^\times) \simeq \text{Fun}_S(K \times N(\mathcal{F} \text{in}_*), N(\Gamma^\times), \mathcal{C}).
\]

Note that for each \( s \in S \), we have a canonical isomorphism \( \tilde{\mathcal{C}}^\times \times_S \{s\} \simeq \tilde{\mathcal{C}}^\times_s \), where \( \tilde{\mathcal{C}}^\times_s \) is obtained by applying Construction 2.4.1.4 to the \( \infty \)-category \( \mathcal{C}_s \). We let \( \mathcal{C}^\times \) denote the full simplicial subset of \( \tilde{\mathcal{C}}^\times \) spanned by those vertices which belong to \( \mathcal{C}^\times_s \subseteq \tilde{\mathcal{C}}^\times_s \), for some vertex \( s \in S \).

Remark 6.3.1.11. Let \( p : \mathcal{C} \to S \) be a locally coCartesian fibration of simplicial sets. We will identify vertices of \( \mathcal{C}^\times \) with triples \( (\langle n \rangle,s,\lambda) \), where \( \langle n \rangle \) is an object of \( N(\mathcal{F} \text{in}_*) \), \( s \) is a vertex of \( S \), and \( \lambda \) is a map from the nerve of the partially ordered set of subsets of \( \langle n \rangle^\circ \simeq \{1,\ldots,n\} \) (ordered by reverse inclusion) to the \( \infty \)-category \( \mathcal{C}_s \).
The fundamental properties of Construction 6.3.1.10 are summarized in the following result:

**Proposition 6.3.1.12.** Let \( p : \mathcal{C} \to S \) be a locally coCartesian fibration of simplicial sets. Then:

1. The projection \( \tilde{q} : \tilde{C}^x \to S \times N(\text{Fin}_n) \) is a locally coCartesian fibration.

2. Let \( \overline{\pi} : (\langle n \rangle, s, \lambda) \to (\langle n' \rangle, t, \lambda') \) be an edge of \( \tilde{C}^x \), so that \( \overline{\pi} \) determines a map \( \alpha : \langle n \rangle \to \langle n' \rangle \) in \( \text{Fin}_n \) and an edge \( e : s \to s' \) in \( S \). Then \( \overline{\pi} \) is locally \( \tilde{q} \)-coCartesian if and only if, for every \( K \subseteq \langle n' \rangle^0 \), the induced map \( \lambda(\alpha^{-1} K) \to \lambda'(K) \) is locally \( p \)-coCartesian.

3. Suppose that each of the \( \infty \)-categories \( \mathcal{E}_\alpha \) admits finite products. Then \( q : \mathcal{C}^x \to S \times N(\text{Fin}_n) \) is a locally coCartesian fibration. Moreover, an edge \( \overline{\pi} : (\langle n \rangle, s, \lambda) \to (\langle n' \rangle, t, \lambda') \) is locally \( q \)-coCartesian if and only if, for every element \( j \in \langle n' \rangle^0 \), the induced map \( \lambda(\alpha^{-1} \{j\}) \to \lambda'(\{j\}) \) is locally \( p \)-coCartesian.

4. Suppose that each of the \( \infty \)-categories \( \mathcal{E}_\alpha \) admits finite products. Then \( q \) exhibits \( \mathcal{C}^x \) as a corepresentable local \( S \)-family of \( \infty \)-operads.

5. Suppose that each \( \mathcal{E}_\alpha \) admits finite products, and let \( \pi : \mathcal{C}^x \to \mathcal{C} \) be the map given by composition with the section \( s : N(\text{Fin}_n) \to N(\Gamma^x) \) defined in Remark 2.4.1.3 (given by \( \langle n \rangle \mapsto (\langle n \rangle, \langle n \rangle^0) \)). Then \( \pi \) is a Cartesian structure on \( \mathcal{C}^x \).

**Proof.** The forgetful functor \( N(\Gamma^x) \to N(\text{Fin}_n) \) is a Cartesian fibration, and therefore a flat categorical fibration (Example B.3.11). It follows from Proposition B.3.14 that \( q \) is a categorical fibration. To prove that \( q \) is a locally coCartesian fibration, it will suffice to show that for every edge \( \Delta^1 \to S \) the induced map \( \Delta^1 \times_S \tilde{C}^x \to \Delta^1 \times N(\text{Fin}_n) \) is a locally coCartesian fibration. We may therefore replace \( S \) by \( \Delta^1 \) and thereby reduce to the case where \( p \) is a coCartesian fibration. Assertions (1) and (2) now follow from Corollary T.3.2.2.13.

We now prove (3). Fix a vertex \( (s, \langle n \rangle) \) of \( S \times N(\text{Fin}_n) \), so that we can identify objects of \( \tilde{C}^x_{s,\langle n \rangle} \) with functors \( N(P(\langle n \rangle^0)) \to \mathcal{E}_\alpha \). The full subcategory \( \mathcal{C}^x_{s,\langle n \rangle} \) is spanned by those functors which are right Kan extensions of their restriction to the full subcategory \( N(P_{\downarrow}(\langle n \rangle^0)) \subseteq N(P(\langle n \rangle^0)) \), where \( P_{\downarrow}(\langle n \rangle^0) \) consists of subsets having cardinality 1. Using our assumption that \( \mathcal{E}_\alpha \) admits finite products, we deduce that the inclusion \( \mathcal{C}^x_{s,\langle n \rangle} \to \tilde{C}^x_{s,\langle n \rangle} \) admits a left adjoint \( L_{s,\langle n \rangle} \). Moreover, a morphism \( \lambda : \lambda' \) in \( \tilde{C}^x_{s,\langle n \rangle} \) is an \( L_{s,\langle n \rangle} \)-equivalence if and only if, for every element \( j \in \langle n \rangle^0 \), the induced map \( \lambda(\{j\}) \to \lambda'(\{j\}) \) is an equivalence.

We now argue that \( q \) is a locally coCartesian fibration. Suppose we are given a vertex \( (\langle n \rangle, s, \lambda) \) in \( \tilde{C}^x_{s,\langle n \rangle} \) and an edge \( \alpha : (\langle n \rangle, s) \to (\langle n' \rangle, t) \) in \( N(\text{Fin}_n) \times S \). Let \( \overline{\alpha} : (\langle n \rangle, s, \lambda) \to (\langle n' \rangle, t, \lambda') \) be a locally \( \tilde{q} \)-coCartesian morphism in \( \tilde{C}^x \) lifting \( \alpha \). Let \( \overline{\alpha'} : \lambda' \to \lambda'' \) be a morphism in the \( \infty \)-category \( \mathcal{E}_{s,\langle n' \rangle} \) which exhibits \( \lambda'' \) as a \( \mathcal{E}_{s,\langle n' \rangle} \)-localization of \( \lambda' \). Since \( \tilde{q} \) is an inner fibration, we can choose a 2-simplex

\[
\begin{tikzcd}
(\langle n \rangle, t, \lambda') \\
(\langle n \rangle, s, \lambda) \\
(\langle n' \rangle, t, \lambda'')
\end{tikzcd}
\]

lifting the degenerate 2-simplex

\[
\begin{tikzcd}
(\langle n \rangle, t) \\
(\langle n \rangle, s) \\
(\langle n' \rangle, t)
\end{tikzcd}
\]

of \( N(\text{Fin}_n) \times S \). We note that \( \overline{\alpha} \) is locally \( \tilde{q} \)-coCartesian. Moreover, condition (2) implies that for every subset \( K \subseteq \langle n \rangle^0 \), \( \overline{\alpha'} \) induces a locally \( p \)-coCartesian edge \( \lambda(\alpha^{-1} K) \to \lambda'(K) \). Since \( \overline{\alpha'} \) is an \( L_{s,\langle n' \rangle} \)-equivalence, it
induces an equivalence $\lambda'(^{n,j}) \Rightarrow \lambda''(^{n,j})$ for each $j \in \langle n \rangle^o$. It follows by transitivity that $\lambda(\alpha^{-1}^{n,j}) \Rightarrow \lambda''(^{n,j})$ is locally $p$-coCartesian for each $j \in \langle n \rangle^o$. This proves the “only if” direction of the final assertion of (3). To prove the converse, suppose we are given an arbitrary edge of $\tilde{\beta} : \langle (n), s, \lambda \rangle \Rightarrow \langle (n'), t, \mu \rangle$ in $C^\infty$ which lifts $\alpha$ and induces locally $p$-coCartesian edges $\lambda(\alpha^{-1}^{n,j}) \Rightarrow \mu(^{n,j})$ for each $j \in \langle n \rangle^o$. Since $\tilde{\beta}$ is locally $q$-coCartesian, we can choose a 2-simplex

$$
\begin{array}{c}
\langle (n'), t, \lambda'' \rangle \\
\alpha \\
\mid \\
\langle (n), s, \lambda \rangle \\
\mid \\
\langle (n'), t, \mu \rangle
\end{array}
$$

where $\gamma$ is a morphism in $C^\infty_{s,(n')}$. Then $\gamma$ induces an equivalence $\lambda''(^{n,j}) \Rightarrow \mu(^{n,j})$ for each $j \in \langle n \rangle^o$. It follows that $\gamma$ is an equivalence, so that $\tilde{\beta}$ is also locally $q$-coCartesian.

We now prove (4). We may assume without loss of generality that $S = \Delta^n$. We will show that it is a corepresentable local $S$-family of $\infty$-categories by verifying the hypotheses of Lemma 6.2.5.18. The third hypothesis is clear (it follows from Proposition 2.4.1.5 that $C^\infty_s \Rightarrow N(\text{Fin}_*)$ is a symmetric monoidal $\infty$-category for each vertex $s \in S$). We will check the first hypothesis; the proof of the second is similar. Suppose we are given a 2-simplex

$$
\begin{array}{c}
\langle (m), s, \lambda' \rangle \\
\beta \\
\mid \\
\langle (m'), s, \lambda \rangle \\
\mid \\
\langle (n), t, \lambda'' \rangle
\end{array}
$$

in $C^\infty$ where $\alpha$ is inert and $\beta$ is locally $q$-coCartesian. Let $\gamma_0 : \langle m' \rangle \Rightarrow \langle n \rangle$ be the image of $\gamma$ in $N(\text{Fin}_*)$, and define $\alpha_0$ and $\beta_0$ similarly. We wish to show that $\gamma$ is locally $q$-coCartesian. Unwinding the definitions, we must show that for $j \in \langle m \rangle^o$, then the induced edge $\lambda(\gamma_0^{-1}^{m,j}) \Rightarrow \lambda''(^{n,j})$ is locally $p$-coCartesian. Since $\beta$ is locally $q$-coCartesian, the edge $\lambda''(\beta_0^{-1}^{m,j}) \Rightarrow \lambda''(^{n,j})$ is locally $p$-coCartesian. It will therefore suffice to show that $\lambda(\gamma_0^{-1}^{m,j}) \Rightarrow \lambda''(\beta_0^{-1}^{m,j})$ is an equivalence, which follows from the inertness of $\alpha$.

To prove (5), we note that the first condition of Definition 6.3.1.17 follows from Proposition 2.4.1.5, and the second follows the description of the class of locally $q$-coCartesian morphisms given by (2) and (3).

Notation 6.3.1.13. Let $S$ be a simplicial set and let $p : C^\otimes \Rightarrow S \times N(\text{Fin}_*)$ and $q : D^\otimes \Rightarrow S \times N(\text{Fin}_*)$ be corepresentable local $S$-families of $\infty$-operads. We let $\text{Fun}_S^\otimes(C^\otimes, D^\otimes)$ denote the full subcategory of $\text{Fun}_{S \times N(\text{Fin}_*)}(C^\otimes, D^\otimes)$ spanned by those maps $F$ which carry locally $p$-coCartesian edges of $C^\otimes$ to locally $q$-coCartesian edges of $D^\otimes$.

Proposition 6.3.1.14. Let $p : C^\otimes \Rightarrow S \times N(\text{Fin}_*)$ be a corepresentable local $S$-family of $\infty$-operads, let $q : D \Rightarrow S$ be a locally coCartesian fibration, and assume that each of the $\infty$-categories $D_s$ admits finite products. Let $\pi : D^\times \Rightarrow D$ be the Cartesian structure of Proposition 2.4.1.5. Then composition with $\pi$ induces a trivial Kan fibration

$$\text{Fun}_S^\otimes(C^\otimes, D^\times) \xrightarrow{\text{Fun}_S^\otimes(C^\otimes, D^\otimes)} \text{Fun}_S^\otimes(C^\otimes, D),$$

where $\text{Fun}_S^\otimes(C^\otimes, D)$ is defined as in Proposition 6.3.1.9.

Proof. Arguing as in the proof of Proposition 6.3.1.9, we can reduce to the case where $S = \Delta^k$ is a simplex (and, in particular, an $\infty$-category). Unwinding the definitions, we can identify $\text{Fun}_S^\otimes(C^\otimes, D^\times)$ with the full subcategory of $\text{Fun}_{S \times N(\text{Fin}_*)}(C^\otimes, D) \Rightarrow \text{Fun}_{S \times N(\text{Fin}_*)}(C \times N(\text{Fin}_*)^\times, D)$ spanned by those functors $F$ which satisfy the following condition:

1. For every vertex $s \in S$ and every object $C \in C^\otimes_s$, and every subset $J \subseteq \langle n \rangle^o$, the functor $F$ induces an equivalence

$$F(C, J) \Rightarrow \prod_{j \in J} F(C, \{j\})$$
in the $\infty$-category $\mathcal{D}_s$.

(2) For every locally $p$-coCartesian morphism $\alpha : C \to C'$ covering a map $\alpha_0 : \langle n \rangle \to \langle n' \rangle$ in $\mathcal{F}_{\text{fin}_s}$, and every element $j \in \langle n' \rangle^\circ$, the induced map $F(C, \alpha^{-1}(j)) \to F(C', \{j\})$ is a locally $q$-coCartesian morphism of $\mathcal{D}$.

The functor $F' = \pi \circ F$ can be described by the formula $F'(C) = F(C, \langle n \rangle^\circ)$, for each $C \in \mathcal{E}_{(n)}$. In other words, $F'$ can be identified with the restriction of $F$ to the full subcategory of $\mathcal{E} \subseteq \mathcal{E} \times_{N(\mathcal{F}_{\text{fin}_s})} N(\Gamma^\times)$ spanned by objects of the form $(C, \langle n \rangle^\circ)$ (note that $\mathcal{E}$ is canonically isomorphic to $\mathcal{E}^\circ$).

Let $X = (C, J)$ be an object of the fiber product $\mathcal{E} \times_{N(\mathcal{F}_{\text{fin}_s})} N(\Gamma^\times)$. Here $C \in \mathcal{E}_{(n)}$ and $J \subseteq \langle n \rangle^\circ$. We claim that the $\infty$-category $\mathcal{E}'_{X/}$ has an initial object. More precisely, if we choose an inert morphism $\alpha : C \to C'$ covering the map $\alpha_0 : \langle n \rangle \to J$, given by the formula

$$
\alpha(j) = \begin{cases} j & \text{if } j \in J \\ * & \text{otherwise}, \end{cases}
$$

then the induced map $\alpha : (C, J) \to (C', J)$ is an initial object of $\mathcal{E}'_{X/}$. It follows that every functor $F' : \mathcal{E}' \to \mathcal{D}$ admits a right Kan extension to $\mathcal{E} \times_{N(\mathcal{F}_{\text{fin}_s})} N(\Gamma^\times)$, and that an arbitrary functor $F : \mathcal{E} \times_{N(\mathcal{F}_{\text{fin}_s})} N(\Gamma^\times) \to \mathcal{D}$ is a right Kan extension of $F|\mathcal{E}'$ if and only if $F(\alpha)$ is an equivalence, for every $\alpha$ defined as above.

Let $\mathcal{E}$ be the full subcategory of $\text{Fun}(\mathcal{E} \times_{N(\mathcal{F}_{\text{fin}_s})} N(\Gamma^\times), \mathcal{D})$ spanned by those functors $F$ which satisfy the following conditions:

(1') The restriction $F' = F|\mathcal{E}'$ is a weak Cartesian structure on $\mathcal{E}' \simeq \mathcal{E}^\circ$.

(2') The functor $F$ is a right Kan extension of $F'$.

Using Proposition T.4.3.2.15, we conclude that the restriction map $\mathcal{E} \to \text{Fun}_\mathcal{E}(\mathcal{E}^\circ, \mathcal{D})$ is a trivial fibration of simplicial sets. To prove that $\theta$ is a trivial Kan fibration, it will suffice to show that conditions (1) and (2) are equivalent to conditions (1') and (2').

Suppose first $F$ is a functor satisfying conditions (1') and (2'). We first verify condition (1). Let $C \in \mathcal{E}_{s,(n)}$, let $J \subseteq \langle n \rangle^\circ$. We wish to show that the canonical map $F(C, J) \to \prod_{j \in J} F(C, \{j\})$ is an equivalence in $\mathcal{D}_s$. Let $\alpha : (C, J) \to (C', J)$ and $\{\alpha_j : (C, \{j\}) \to (C', \{j\})\}_{j \in J}$ be defined as above. We have a commutative diagram

$$
\begin{array}{ccc}
F(C, J) & \longrightarrow & \prod_{j \in J} F(C, \{j\}) \\
\downarrow & & \downarrow \\
F(C', J) & \longrightarrow & \prod_{j \in J} F(C'_j, \{j\})
\end{array}
$$

in the $\infty$-category $\mathcal{D}_s$. Using condition (2'), we deduce that the vertical maps are equivalences. It will therefore suffice to show that the lower horizontal map is an equivalence, which follows immediately from (1').

We now verify condition (2). Choose a locally $p$-coCartesian morphism $\beta : C \to C'$ covering a map $\beta : \langle n \rangle \to \langle n' \rangle$ in $\mathcal{F}_{\text{fin}_s}$ and let $j \in \langle n' \rangle^\circ$. We wish to prove that the induced map $F(C, \beta^{-1}(j)) \to F(C', \{j\})$ is locally $q$-coCartesian. Lift the morphism $\rho : \langle n \rangle \to \langle 1 \rangle$ to an inert morphism $C' \to C''$ in $\mathcal{E}^\circ$. Condition (2') implies the induced map $F(C', \{j\}) \to F(C'', \{1\})$ is an equivalence. We may therefore replace $C'$ by $C''$ and thereby reduce to the case where $n' = 1$. The map $\beta$ factors as a composition

$$
C \xrightarrow{\beta} C_0 \xrightarrow{\beta''} C'
$$

where $\beta$ is inert and $\beta''$ is active. Using (2') again, we deduce that $F(\beta')$ is an equivalence. We may therefore replace $C$ by $C_0$ and thereby reduce to the case where $\beta'$ is active, so that $\beta^{-1}\{1\} = \langle n \rangle^\circ$. We are therefore reduced to proving that $F(\beta)$ is locally $p$-coCartesian, which follows from (1').
Now suppose that $F$ satisfies (1) and (2). We first verify that $F$ satisfies (2'). Fix an object $C \in C_{s(n)}$ and a subset $J \subseteq \langle n \rangle^2$, and choose an inert morphism $C \to C'$ covering the canonical map $\langle n \rangle \to J_s$. We wish to prove that the induced map $F(C, J) \to F(C', J)$ is an equivalence in $D$. Using condition (1), we are reduced to proving that the induced map $F(C, \langle j \rangle) \to F(C', \langle j \rangle)$ is an equivalence for each $j \in J$, which is a special case of (2).

We now verify condition (1'). We first show that for each vertex $s \in S$, $F'$ induces a weak Cartesian structure on the $\infty$-operad $O_s$. Suppose that $C \in C_{s(n)}$, and choose inert morphisms $C \to C_i$ lying over $\rho^i : \langle n \rangle \to \langle 1 \rangle$ for $1 \leq i \leq n$. We wish to show that the induced maps $F'(C) \to F'(C_i)$ exhibit $F'(C)$ as a product of the objects $F(C_i)$ in the $\infty$-category $D_s$. It follows from condition (1) that $F'(C)$ is a product of the objects $F(C, \{i\})$ for $1 \leq i \leq n$. It therefore suffices to show that each of the maps $F(C, \{i\}) \to F(C, \{1\})$ is an equivalence, which follows from (2). To complete the proof that $F'$ is a weak Cartesian structure on $O$, it suffices to show that if $e : C \to C'$ is a locally $p$-coCartesian morphism in $O$ covering an active map $\langle n \rangle \to \langle 1 \rangle$ in $N(Fin_n)$, then $F'(e)$ is locally $q$-coCartesian. This is also a special case of assumption (2). □

**Theorem 6.3.1.15.** Fix a simplicial set $S$.

1. Let $p : C \to S$ be a locally coCartesian fibration, and suppose that for each vertex $s \in S$, the $\infty$-category $C_s$ admits finite products. Then there exists a Cartesian local $S$-family of $\infty$-operads $p : O^\otimes \to S \times N(Fin_n)$ and a Cartesian structure $\pi : O^\otimes \to C$. In particular, there is an equivalence $C \simeq O$ (of locally coCartesian fibrations over $S$).

2. Let $p : C^\otimes \to S \times N(Fin_n)$ and $q : D^\otimes \to S \times N(Fin_n)$ be Cartesian $S$-families of $\infty$-operads, let $Fun^S_S(C^\otimes, D^\otimes)$ be defined as in Notation 6.3.1.13, and let $Fun^S_S(C, D)$ be defined as in Proposition 6.3.1.9. Then the restriction map $\theta : Fun^S_S(C^\otimes, D^\otimes) \to Fun^S_S(C, D)$ is an equivalence of $\infty$-categories.

**Proof.** Assertion (1) follows immediately from Proposition 2.4.1.5. To prove (2), we first define $D^\otimes$ as in the proof of Proposition 2.4.1.5. Since $D^\otimes$ is a Cartesian $S$-family of $\infty$-operads, Proposition 6.3.1.9 implies that there exists a Cartesian structure $\pi : D^\otimes \to D$. Using Proposition 6.3.1.14, we can assume that $\pi$ factors as a composition

$$D^\otimes \xrightarrow{\phi} D^\times \xrightarrow{\pi'} D,$$

where $\pi'$ is the Cartesian structure of Proposition 2.4.1.5 and $\phi \in Fun^S_S(D^\otimes, D^\times)$. For every vertex $s \in S$ and each $\langle n \rangle \in N(Fin_n)$, the induced map

$$D^\otimes_{s(n)} \to D^\times_{s(n)}$$

is an equivalence of $\infty$-categories (since both sides can be identified with the $n$th power of the $\infty$-category $D_s$). It follows that $\phi$ is a categorical equivalence. We may therefore replace $D^\otimes$ by $D^\times$. In this case, the functor $\theta$ factors as a composition

$$Fun^S_S(C^\otimes, D^\times) \xrightarrow{\phi'} Fun^S_S(C^\otimes, D) \xrightarrow{\theta'} Fun^S_S(C, D),$$

where $\theta'$ is an equivalence of $\infty$-categories by Proposition 6.3.1.14 and $\theta''$ is an equivalence of $\infty$-categories by Proposition 6.3.1.9. □

### 6.3.2 Composition of Correspondences

Let $F : C \to D$ be a reduced functor between compactly generated pointed $\infty$-categories which commutes with filtered colimits. Propositions 6.3.0.14 and 6.3.1.3 can be summarized informally as follows: the symmetric sequences $\partial^*(id_C)$ and $\partial^*(id_D)$ are equipped with coherently associative comultiplications

$$\partial^*(id_C) \to \partial^*(id_C) \circ \partial^*(id_C), \quad \partial^*(id_D) \to \partial^*(id_D) \circ \partial^*(id_D),$$
and the symmetric sequence $\partial^*(F)$ is equipped with commuting coactions

$$\partial^*(F) \to \partial^*(\text{id}_2) \circ \partial^*(F) \quad \partial^*(F) \to \partial^*(F) \circ \partial^*(\text{id}_2).$$

We can regard these assertions as a dual version of parts (1) and (2) of Conjecture 6.3.0.7. In this section, we will study the analogue of the third part of Conjecture 6.3.0.7. That is, we wish to show that if $G : \mathcal{D} \to \mathcal{E}$ is another reduced functor between compactly generated pointed $\infty$-categories which commutes with filtered colimits, then the symmetric sequence $\partial^*(G \circ F)$ can be regarded as a kind of tensor product of $\partial^*(G)$ with $\partial^*(F)$ over $\partial^*(\text{id}_\mathcal{D})$. We begin by formalizing this idea more precisely using the language of stable families of $\infty$-operads.

Suppose that $p : \mathcal{O}^\otimes \to \Delta^2 \times \text{N}({\mathcal{F}\text{in}_*})$ is a corepresentable $\Delta^2$-family of $\infty$-operads. Taking the fibers of the map $\mathcal{O}^\otimes \to \Delta^2$, we obtain corepresentable $\infty$-operads $\mathcal{O}_0^\otimes$, $\mathcal{O}_1^\otimes$, and $\mathcal{O}_2^\otimes$, and in particular we obtain tensor product functors

$$\mathcal{O}_i^\otimes : \mathcal{O}_0^\otimes \to \mathcal{O}_1^\otimes \quad \mathcal{O}_j^\otimes : \mathcal{O}_i^\otimes \to \mathcal{O}_2^\otimes \quad \mathcal{O}_i^\otimes \to \mathcal{O}_2^\otimes (\text{see Remark 6.2.4.4}).$$

Taking the inverse image of edges in $\Delta^2$, we obtain corepresentable correspondences from $\mathcal{O}_i^\otimes$ to $\mathcal{O}_j^\otimes$ for $i < j$. In particular, for every finite set $I$, we obtain functors

$$F^I : \mathcal{O}_0^\otimes \to \mathcal{O}_1^\otimes \quad G^I : \mathcal{O}_1^\otimes \to \mathcal{O}_2^\otimes \quad H^I : \mathcal{O}_0^\otimes \to \mathcal{O}_2^\otimes (\text{see the discussion following Definition 6.3.1.1}).$$

Every equivalence relation $E$ on a finite set $I$ determines a 2-simplex $(0, I) \to (1, (I/E)_*) \to (2, (1))$ in $\Delta^2 \times \text{N}(\mathcal{F}\text{in}_*)$, to which the locally coCartesian fibration $p$ associates a natural transformation

$$H^I \to G^I/E \times \prod_{J \in I/E} F^J$$

of functors from $\mathcal{O}_0^\otimes$ to $\mathcal{O}_2^\otimes$. If $\mathcal{O}^\otimes$ is a stable $\Delta^2$-family of $\infty$-operads, then we obtain a map of symmetric sequences $\delta : H^* \to G^* \circ F^*$ in the $\infty$-category $\text{SSeq}(\mathcal{O}_0^\otimes, \mathcal{O}_2^\otimes)$. By studying the restriction of $p$ to 3-simplices of $\Delta^2 \times \text{N}(\mathcal{F}\text{in}_*)$, it is not difficult to verify that the diagram of symmetric sequences

$$\begin{array}{ccc}
H^* & \xrightarrow{\delta} & G^* \circ F^* \\
\downarrow{\delta} & & \downarrow{\text{id} \times \phi} \\
G^* \circ F^* & \xrightarrow{\psi \circ \text{id}} & G^* \circ \otimes^*_1 \circ F^*
\end{array}$$

commutes up to homotopy, where $\phi : F^* \to \otimes^*_1 \circ F^*$ and $\psi : G^* \to G^* \circ \otimes^*_1$ are given by the coactions of $\otimes^*_1$ on $F^*$ and $G^*$, respectively. By studying the inverse image under $p$ of higher-dimensional simplices of $\Delta^2 \times \text{N}(\mathcal{F}\text{in}_*)$, we obtain certain higher coherence conditions. We may summarize the situation informally as follows:

(*) A stable $\Delta^2$-family of $\infty$-operads $\mathcal{O}^\otimes \to \Delta^2 \times \text{N}(\mathcal{F}\text{in}_*)$ determines coalgebras $\otimes^*_i \in \text{SSeq}(\mathcal{O}_i, \mathcal{O}_i)$, an $\otimes^*_1 \otimes^*_0$ bimodule $F^* \in \text{SSeq}(\mathcal{O}_0, \mathcal{O}_1)$, an $\otimes^*_2 \otimes^*_1$ bimodule $G^* \in \text{SSeq}(\mathcal{O}_1, \mathcal{O}_2)$, and a map of $\otimes^*_2 \otimes^*_0$ bimodules $H^* \to G^* \circ \otimes^*_1 F^*$ in $\text{SSeq}(\mathcal{O}_0, \mathcal{O}_2)$.

Now suppose we are given compactly generated pointed $\infty$-categories $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$, together with reduced functors $F : \mathcal{C} \to \mathcal{D}$, $G : \mathcal{D} \to \mathcal{E}$, and $H : \mathcal{C} \to \mathcal{E}$ commuting with filtered colimits, and a natural transformation $\alpha : H \to G \circ F$. We can encode this data by locally coCartesian fibration $M : \Delta^2 \to \Delta^2$, and $M_1 \simeq \mathcal{C}$, $M_2 \simeq \mathcal{D}$, and $M_3 \simeq \mathcal{E}$. Let $p : M^\otimes \to \Delta^2 \times \text{N}(\mathcal{F}\text{in}_*)$ be as in Construction 6.3.1.10. Then $p$ is a differentiable $\Delta^2$-family of $\infty$-operads, so it admits a stabilization $q : \mathcal{O}^\otimes \to \Delta^2 \times \text{N}(\mathcal{F}\text{in}_*)$. According to (*), the stable $\Delta^2$-family of $\infty$-operads $q$ determines a map of symmetric sequences

$$\alpha^+ : \partial^*(H) \to \partial^*(G) \circ \partial^*(\text{id}_2) \circ \partial^*(F).$$
6.3. THE CHAIN RULE

We would like to say that if \( \alpha \) is an equivalence (that is, if the map \( M \to \Delta^2 \) is actually a coCartesian fibration), then the map \( \alpha^+ \) is also an equivalence. What we will actually prove is a reformulation of this assertion, which does not require us to define (relative) composition products of symmetric sequences or to justify the heuristic (\( \ast \)) given above. Our reformulation is based on the notion of a thin \( \Delta^2 \)-family of \( \infty \)-operads (Definition 6.3.2.12). Informally speaking, a stable \( \Delta^2 \)-family of \( \infty \)-operads \( \mathcal{C}^q \to \Delta^2 \times N(\text{Fin}_n) \) is thin if it determines a morphism \( H^\ast \to G^\ast \circ \otimes ; F^\ast \) which is an equivalence in \( \text{SSeq}_q(\emptyset_0, \emptyset_2) \). However, the precise definition of thinness does not directly refer to the theory of symmetric sequences, and makes sense also in unstable situations. Granting the notion of flatness, we can formulate our main result as follows:

**Theorem 6.3.2.1.** Let \( p : \mathcal{C} \to \Delta^2 \) be a coCartesian fibration. Assume that the fibers of \( p \) are pointed and compactly generated, and that for \( i < j \) the induced functor \( \mathcal{C}_i \to \mathcal{C}_j \) is reduced and preserves filtered colimits. Let \( q : \mathcal{C}^q \to \Delta^2 \times N(\text{Fin}_n) \) be a stabilization of the differentiable \( \Delta^2 \)-family of \( \infty \)-operads \( \mathcal{C}^\ast \to \Delta^2 \to N(\text{Fin}_n) \). Then \( \mathcal{C}^q \) is a thin \( \Delta^2 \)-family of \( \infty \)-operads.

Theorem 6.3.2.1 is an immediate consequence of the following pair of assertions:

**Theorem 6.3.2.2.** Let \( p : \mathcal{C}^q \to \Delta^2 \times N(\text{Fin}_n) \) be a Cartesian \( \Delta^2 \)-family of \( \infty \)-operads, and suppose that the underlying locally coCartesian fibration \( p_0 : \mathcal{C} \to \Delta^2 \) is a coCartesian fibration. Then \( \mathcal{C}^q \) is a thin \( \Delta^2 \)-family of \( \infty \)-operads.

**Theorem 6.3.2.3.** Let \( q : \mathcal{C}^q \to \Delta^2 \times N(\text{Fin}_n) \) be a corepresentable \( \Delta^2 \)-family of \( \infty \)-operads. Assume that:

1. Each of the \( \infty \)-categories \( \mathcal{C}_i \) is pointed and compactly generated.
2. For every pair of indices \( 0 \leq i \leq j \leq 2 \) and every finite set \( I \), the induced functor \( \mathcal{C}^q_i \to \mathcal{C}_j \) preserves filtered colimits and zero objects.
3. Let \( 0 \leq i \leq 2 \), let \( \alpha : \langle m \rangle \to \langle n \rangle \) be an injective map of pointed finite sets, and let \( \pi \) be a morphism in \( \mathcal{C}^q \) lifting the induced map \( (i, \langle m \rangle) \to (i, \langle n \rangle) \). If \( \alpha \) is locally \( q \)-coCartesian, then \( \alpha \) is \( q \)-coCartesian.

Let \( \mathcal{C}^q \to \Delta^2 \times N(\text{Fin}_n) \) be a stabilization of \( \mathcal{C}^q \). If \( \mathcal{C}^q \) is a thin \( \Delta^2 \)-family of \( \infty \)-operads, then \( \mathcal{C}^q \) is also a thin \( \Delta^2 \)-family of \( \infty \)-operads.

**Remark 6.3.2.4.** Let \( q : \mathcal{C}^q \to \Delta^2 \times N(\text{Fin}_n) \) be a corepresentable \( \Delta^2 \)-family of \( \infty \)-operads satisfying conditions (1) and (2). Then each of the \( \infty \)-categories \( \mathcal{C}_i \) admits a zero object \( *_i \). If \( S \) is a finite set and \( 0 \leq i \leq j \leq 2 \), then \( q \) determines a functor \( F^S_{i,j} : \mathcal{C}^q_i \to \mathcal{C}_j \) satisfying \( F^S_{i,j}(*_i, *_i, \ldots, *_i) \simeq *_j \). Moreover, for every finite set \( T \), we have canonical maps

\[
F^S_{i,j}(\{X_s\}_{s \in S}) \to F^S_{i,j,T}(\{X_s\}_{s \in S}, \{*_i\}_{t \in T}).
\]

Condition (3) of Theorem 6.3.2.1 asserts that each of these maps is an equivalence. Note that this condition is automatically satisfied if \( q \) is a Cartesian \( \Delta^2 \)-family of \( \infty \)-operads.

We will prove Theorem 6.3.2.2 at the end of this section. The proof of Theorem 6.3.2.3 is quite a bit more difficult, and will be given in \( \S 6.3.6 \).

Our first step is to define the notion of a thin \( \Delta^2 \)-family of \( \infty \)-operads. This will require a brief digression. Suppose that \( q : X \to S \) is a locally coCartesian fibration of simplicial sets. Then every edge \( e : s \to t \) in \( S \) induces a functor of \( \infty \)-categories \( X_s \to X_t \). More generally, we can associate to every \( n \)-simplex \( \sigma : \Delta^n \to S \) a functor from \( X_{\sigma(0)} \) to \( X_{\sigma(n)} \), given by the composition of the functors

\[
\theta(\sigma) : X_{\sigma(0)} \to X_{\sigma(1)} \to \cdots \to X_{\sigma(n)}
\]

associated to the edges belonging to the “spine” of \( \Delta^n \). If \( q \) is a coCartesian fibration, then the functor \( \theta(\sigma) \) depends only on the edge \( \sigma(0) \to \sigma(n) \) of \( S \) determined by \( \sigma \). However, if we assume only that \( q \) is a locally coCartesian fibration, then \( \theta(\sigma) \) depends on the entire simplex \( \sigma \). We will need to precisely articulate the sense in which the functor \( \theta(\sigma) \) depends on \( \sigma \).
Notation 6.3.2.5. Let $S$ be a simplicial set. We let $\Delta_S$ denote the category of simplices of $S$. The objects of $\Delta_S$ are maps $\sigma : \Delta^m \to S$. Given a pair of objects $\sigma : \Delta^m \to S$ and $\tau : \Delta^n \to S$, we let $\text{Hom}_{\Delta_S}(\sigma, \tau)$ denote the collection of commutative diagrams

\[
\begin{tikzcd}
\Delta^m 
& \Delta^n \\
S. 
& \sigma 

\end{tikzcd}
\]

Suppose we are given a pair of vertices $s, t \in S$. We define a subcategory $\Delta_S^{s,t}$ as follows:

(i) An object $\sigma : \Delta^m \to S$ belongs to $\Delta_S^{s,t}$ if $n \geq 1$, $\sigma(0) = s$, and $\sigma(n) = t$.

(ii) Given objects $\sigma, \tau \in \Delta_S^{s,t}$, a commutative diagram

\[
\begin{tikzcd}
\Delta^m 
& \Delta^n \\
S. 
& \sigma 

\end{tikzcd}
\]

determines a morphism in $\Delta_S^{s,t}$ if and only if $\theta(0) = 0$ and $\theta(m) = n$.

Construction 6.3.2.6. Let $q : X \to S$ be a locally coCartesian fibration of simplicial sets, and suppose we are given vertices $s, t \in S$. We define a functor $\phi : (\Delta_S^{s,t})^{\text{op}} \to \text{Set}_\Delta$ by the formula $\phi(\sigma : \Delta^m \to S) = \text{Fun}_S(\Delta^m, X)^{\text{op}}$. Let $\mathcal{Z}$ denote the opposite of the relative nerve $N_q((\Delta_S^{s,t}))$ (see Definition T.3.2.5.2). Then $\mathcal{Z}$ is an $\infty$-category equipped with a Cartesian fibration $\mathcal{Z} \to N(\Delta_S^{s,t})$. Unwinding the definitions, we can identify the objects of $\mathcal{Z}$ with simplices $\sigma : \Delta^n \to X$ such that $n \geq 1$, $\sigma(0) \in X_s$, and $\sigma(n) \in X_t$. Note that the evaluation maps $\sigma \mapsto \sigma(0)$ and $\tau \mapsto \tau(0)$ determine functors $e_s : \mathcal{Z}_q \to X_s$ and $e_t : \mathcal{Z}_q \to X_t$.

Let $\mathcal{Z}_q^0$ denote the full subcategory of $\mathcal{Z}$ spanned by those simplices $\sigma : \Delta^n \to X$ such that, for each $1 \leq i \leq n$, the map $\sigma(i-1) \to \sigma(i)$ is locally $q$-coCartesian.

Lemma 6.3.2.7. Let $q : X \to S$ be a locally coCartesian fibration of simplicial sets, let $s, t \in S$ be vertices, and let $\mathcal{Z}_q^0 \subseteq \mathcal{Z}$ be defined as in Construction 6.3.2.6. For each $\sigma \in \Delta_S^{s,t}$, let $\mathcal{Z}_\sigma$ denote the fiber of $\mathcal{Z} \to N(\Delta_S^{s,t})^{\text{op}}$ over $\sigma$, and define $\mathcal{Z}_\sigma^0$ similarly. Then:

(a) For each $\sigma \in \Delta_S^{s,t}$, the map $e_s$ induces a trivial Kan fibration $\mathcal{Z}_\sigma^0 \to X_s$.

(b) For every object $\sigma \in \Delta_S^{s,t}$, the inclusion $\mathcal{Z}_\sigma^0 \hookrightarrow \mathcal{Z}_\sigma$ admits a right adjoint $L_\sigma$. Moreover, if $\alpha$ is a morphism in $\mathcal{Z}_\sigma$, then $L_\sigma(\alpha)$ is an equivalence if and only if $e_0(\alpha)$ is an equivalence, where $e_0 : \mathcal{Z}_\sigma \to X_s$ is defined as in Construction 6.3.2.6.

(c) The forgetful functor $f : \mathcal{Z} \to N(\Delta_S^{s,t})^{\text{op}}$ restricts to a Cartesian fibration $f^0 : \mathcal{Z}_q^0 \to N(\Delta_S^{s,t})$.

(d) The map $e_s$ induces an equivalence of $\infty$-categories

\[
\mathcal{Z}_\sigma^0 \to X_s \times N(\Delta_S^{s,t}).
\]

Proof. We first prove (a). Fix an object $\sigma : \Delta^n \to S$ of $\Delta_S^{s,t}$. For $0 \leq j \leq n$, let

\[
\mathcal{C}_j = \text{Fun}_S(\Delta^{[0,1]} \coprod_{\{1\}} \Delta^{[1,2]} \coprod_{\{j-1\}} \cdots \coprod_{\{j-1\}} \Delta^{(j-1,j)}, X),
\]

and let $\mathcal{C}_j'$ denote the full subcategory of $\mathcal{C}_j$ spanned by those diagrams which carry each edge $\Delta^{(i-1,i)}$ to a $q$-coCartesian edge of $X$ for $1 \leq i \leq j$. Each of the restriction maps $\mathcal{C}_j' \to \mathcal{C}_{j-1}'$ is a pullback of the restriction map

\[
r_j : \text{Fun}_S(\Delta^{(j-1,j)}, X) \to \text{Fun}_S(\{j-1\}, X),
\]
where \( \text{Fun}_S(\Delta^{(j-1,j)}, X) \) denotes the full subcategory of \( \text{Fun}_S(\Delta^{(j-1,j)}, X) \) spanned by the locally \( q \)-coCartesian edges. Proposition T.4.3.2.15 (and our assumption that \( q \) is a locally coCartesian fibration) imply that each \( r_j \) is a trivial Kan fibration. We have a pullback diagram

\[
\begin{array}{ccc}
\Delta^{(0,1)} \coprod_{\{1\}} \Delta^{(1,2)} \coprod \cdots \coprod_{\{n-1\}} \Delta^{(n-1,n)} & \hookrightarrow & \Delta^n \\
\downarrow & & \downarrow \\
\mathcal{C}_n & \cong & \mathcal{C}_n.
\end{array}
\]

The lower horizontal map is a trivial Kan fibration because the inclusion

\[
\Delta^{(0,1)} \coprod_{\{1\}} \Delta^{(1,2)} \coprod \cdots \coprod_{\{n-1\}} \Delta^{(n-1,n)} \hookrightarrow \Delta^n
\]

is inner anodyne. It follows that the restriction map \( \mathcal{Z}_0^0 \to \mathcal{C}_n \) is a trivial Kan fibration, so that the composite map

\[
\theta : \mathcal{Z}_0^0 \to \mathcal{C}_n \to \mathcal{C}_{n-1} \to \cdots \to \mathcal{C}_1 \to \mathcal{C}_0 \simeq X_s
\]

is a trivial Kan fibration, as desired.

We now prove (b). Let \( \sigma \) be as above, and let \( s : X_s \to \mathcal{Z}_0^0 \) be a section of the trivial Kan fibration \( \theta_0 : \mathcal{Z}_0^0 \). We will show that the identity map \( \text{id}_{X_s} \to \theta_0 \circ s \) exhibits \( s \) as a left adjoint to \( \theta_0 \); it will then follow from (a) that the composition \( s \circ \theta_0 \) is a right adjoint to the inclusion. Fix an object \( x \in X_s \) and an object \( z \in \mathcal{Z}_\sigma \); we wish to show that the canonical map

\[
\text{Map}_{\mathcal{Z}_\sigma}(s(x), z) \to \text{Map}_{X_s}(x, \theta_0(z))
\]

is a homotopy equivalence. For each \( 0 \leq j \leq n \), let \( \theta_j : \mathcal{Z}_\sigma \to \mathcal{C}_j \) be the restriction functor. We will prove that each of the maps

\[
\text{Map}_{\mathcal{Z}_\sigma}(s(x), z) \to \text{Map}_{\mathcal{C}_j}(\theta_j(s(x), \theta_j(z))
\]

is a homotopy equivalence using descending induction on \( j \). When \( j = n \), the desired result is obvious (since \( \theta_n \) is a trivial Kan fibration), and when \( j = 0 \) it will imply the desired result. To carry out the inductive step, it will suffice to show that the map

\[
u : \text{Map}_{\mathcal{C}_j}(\theta_j(s(x), \theta_j(z)) \to \text{Map}_{\mathcal{C}_{j-1}}(\theta_{j-1}(s(x), \theta_{j-1}(z))
\]

is a homotopy equivalence. Let \( x' \) and \( z' \) be the images of \( s(x) \) and \( z \) in \( \text{Fun}_S(\Delta^{(j-1,j)}, X) \) and let \( x_0' \) and \( z_0' \) be their images in \( X_{\sigma(j-1)} \). Then \( u \) is a pullback of the restriction map

\[
\text{Map}_{\text{Fun}_S(\Delta^{(j-1,j)}, X)}(x', z') \to \text{Map}_{X_{\sigma(j-1)}}(x_0', z_0'),
\]

which is a homotopy equivalence by virtue of the fact that \( x' \) is a locally \( q \)-coCartesian edge of \( X \).

Assertion (c) follows from (b) and Lemma 2.2.1.11, and assertion (d) follows from Corollary T.2.4.4.4 together with (a) and (c).

**Definition 6.3.2.8.** Let \( q : X \to S \) be a locally coCartesian fibration of simplicial sets. Let \( s, t \in S \) be vertices, let \( \mathcal{Z}_0^0 \subseteq \mathcal{Z} \) be defined as in Construction 6.3.2.6, and let \( h : X_s \times N(\Delta_S^{s,t}) \to \mathcal{Z}_0^0 \) be a homotopy inverse to the equivalence of \( \infty \)-categories \( \mathcal{Z}_0^0 \to X_s \times N(\Delta_S^{s,t}) \) of Lemma 6.3.2.7. The composite map

\[
X_s \times N(\Delta_S^{s,t}) \xrightarrow{h} \mathcal{Z}_0^0 \subseteq \mathcal{Z} \xrightarrow{\tau} X_t
\]

determines a functor \( \theta : N(\Delta_S^{s,t}) \to \text{Fun}(X_s, X_t) \), which is well-defined up to homotopy. We will refer to \( \theta \) as the *spray* associated to \( q \).
Remark 6.3.2.9. In the situation of Definition 6.3.2.8, suppose that $\sigma : \Delta^n \to S$ is an object of $\Delta^{s,t}_S$, so that $\sigma$ determines a sequence of edges

$$s = s_0 \xrightarrow{f(1)} s_1 \xrightarrow{f(2)} \cdots \xrightarrow{f(n)} s_n = t.$$ 

Since $q$ is a coCartesian fibration, each of the edges $f(i)$ determines a functor $f(i)_! : X_{\sigma(i-1)} \to X_{\sigma(i)}$. If $\theta : N(\Delta^{s,t}_S) \to \text{Fun}(X_s, X_t)$ is the spray associated to $q$, then $\theta(\sigma)$ is given (up to homotopy) by the composition $f(n) \circ f(n-1) \circ \cdots \circ f(1)$. 

Remark 6.3.2.10. In the situation of Definition 6.3.2.8, suppose that the map $q : X \to S$ is a coCartesian fibration of simplicial sets. Then the spray $\theta : N(\Delta^{s,t}_S) \to \text{Fun}(X_s, X_t)$ is locally constant: that is, it carries each morphism in $\Delta^{s,t}_S$ to an equivalence in $\text{Fun}(X_s, X_t)$.

Notation 6.3.2.11. Let $S$ be a finite set, and let $\text{Equiv}(S)$ be the partially ordered set of equivalence relations on $S$ (see Construction 6.3.3.12). We let $\text{Part}(S)$ denote the partially ordered set consisting of linearly ordered subsets of $\text{Equiv}(S)$. We regard $\text{Part}(S)$ as partially ordered with respect to inclusions. Let $\text{Part}^0(S) \subseteq \text{Part}(S)$ denote the subset consisting of nonempty linearly ordered subsets of $\text{Equiv}(S)$.

Suppose that $S = \{1, \ldots, n\}$. The construction

$$(E \in \text{Equiv}(S)) \mapsto (S/E)_*$$

determines a functor $\text{Equiv}(S) \to \mathcal{F}\text{in}_*$. Let $s = (0, \langle n \rangle) \in \Delta^2 \times N(\mathcal{F}\text{in}_*)$ and $t = (2, \langle 1 \rangle) \in \Delta^2 \times N(\mathcal{F}\text{in}_*)$. We define a functor

$$\chi : \text{Part}(S) \to \Delta^{s,t}_{\Delta^2 \times N(\mathcal{F}\text{in}_*)}$$

as follows: to every chain of equivalence relations $E_1 \subseteq E_2 \subseteq \cdots \subseteq E_k$ in $\text{Equiv}(S)$, $\chi$ associates the $(k + 1)$-simplex of $\Delta^2 \times N(\mathcal{F}\text{in}_*)$ given by the sequence of active morphisms

$$(0, \langle n \rangle) \to (1, (S/E_1)_*) \to (1, (S/E_2)_*) \to \cdots \to (1, (S/E_k)_*) \to (2, \langle 1 \rangle).$$

Definition 6.3.2.12. Let $q : \mathcal{O}^\otimes \to \Delta^2 \times N(\mathcal{F}\text{in}_*)$ be a $\Delta^2$-family of $\infty$-operads. We will say that $\mathcal{O}^\otimes$ is thin if is corepresentable, the $\infty$-category $\mathcal{O}_2$ admits finite limits and the following condition is satisfied for each $n \geq 1$:

(*) Let $S = \{1, \ldots, n\}$, let $T = \Delta^2 \times N(\mathcal{F}\text{in}_*)$, let $\chi : \text{Part}(S) \to \Delta^{s,t}_T$ be as in Notation 6.3.2.11 and let $\theta : N(\Delta^{s,t}_T) \to \text{Fun}(\mathcal{O}^\otimes_{\langle n \rangle}, \mathcal{O})$ be the spray associated to $q$ (see Definition 6.3.2.8). Then the composite map

$$N(\text{Part}^0(S))^c \simeq N(\text{Part}(S)) \xrightarrow{\chi} N(\Delta^{s,t}_T) \xrightarrow{\theta} \text{Fun}(\mathcal{O}^\otimes_{\langle 0, (n) \rangle}, \mathcal{O}^\otimes_{\langle 2, (1) \rangle}) \simeq \text{Fun}(\mathcal{O}^\otimes_0, \mathcal{O}_2)$$

is a limit diagram in the $\infty$-category $\text{Fun}(\mathcal{O}^\otimes_0, \mathcal{O}_2)$.

Remark 6.3.2.13. Let $q : \mathcal{O}^\otimes \to \Delta^2 \times N(\mathcal{F}\text{in}_*)$ be a corepresentable $\Delta^2$-family of $\infty$-operads, so that $q$ determines functors

$$\otimes^m_0 : \mathcal{O}^\otimes_0 \to \mathcal{O}_0 \quad \otimes^m_1 : \mathcal{O}^\otimes_1 \to \mathcal{O}_1 \quad \otimes^m_2 : \mathcal{O}^\otimes_2 \to \mathcal{O}_2$$

$$F^m : \mathcal{O}^\otimes_0 \to \mathcal{O}_1 \quad G^m : \mathcal{O}^\otimes_1 \to \mathcal{O}_2 \quad H^m : \mathcal{O}^\otimes_2 \to \mathcal{O}_2$$

for every integer $m \geq 0$. When $n = 1$, condition (*) of Definition 6.3.2.12 asserts that for every object $X \in \mathcal{O}_0$, the canonical map $H^1(X) \to G^1(F^1(X))$ is an equivalence. When $n = 2$, condition (*) of Definition 6.3.2.12 guarantees that for every pair of objects $X, Y \in \mathcal{O}_0$, the diagram

$$\begin{array}{ccc}
H^2(X, Y) & \longrightarrow & G^1(F^2(X, Y)) \\
\downarrow & & \downarrow \\
G^2(F^1(X), F^1(Y)) & \longrightarrow & G^1(F^1(X) \otimes^2_1 F^1(X)).
\end{array}$$

For larger values of $n$, condition (*) guarantees that the functor $H^m : \mathcal{O}^\otimes_0 \to \mathcal{O}_2$ can be recovered as the limit of a finite diagram of functors obtained by composing the functors $F^p, G^q,$ and $\otimes^r_1$ for $p, q, r > 0$. 

Remark 6.3.2.14. To place Definition 6.3.2.12 in context, we remark that there exists an \((\infty, 2)\)-category \(SSeq\) which may be described roughly as follows:

- The objects of \(SSeq\) are pairs \((0, U^*)\), where \(0\) is a stable \(\infty\)-category and \(U^*\) is a coalgebra object of \(SSeq(0, 0)\) whose counit induces an equivalence \(U^1 \to \text{id}_0\) (equivalently, we can define the objects of \(SSeq\) to be unital stable \(\infty\)-operads: see Remark 6.3.0.10).

- Given a pair of objects \((0, U^*), (0', U'^*) \in \text{SSeq}\), the \(\infty\)-category of morphisms from \((0, U^*)\) to \((0', U'^*)\) in \(SSeq\) can be identified with the collection of \(U'^* - U^*\) module objects of \(SSeq(0, 0')\) (which we can think of as stable correspondences between the corresponding stable \(\infty\)-operads: see Remark 6.3.1.2).

Every stable \(\Delta^2\)-family of \(\infty\)-operads \(q : 0^\otimes \to \Delta^2 \times N(\text{Fin}_*)\) determines 1-morphisms
\[
f : (0_0, \otimes^*_0) \to (0_1, \otimes^*_1) \quad g : (0_1, \otimes^*_1) \to (0_2, \otimes^*_2) \quad h : (0_2, \otimes^*_2) \to (0_2, \otimes^*_2)
\]
together with a 2-morphism \(\alpha : h \to g \circ f\) in the \((\infty, 2)\)-category \(SSeq\). The thinness of \(q\) is equivalent to the invertibility of the 2-morphism \(\alpha\).

We warn the reader that this \((\infty, 2)\)-categorical interpretation of Definition 6.3.2.12 is specific to the case of stable families of \(\infty\)-operads, and can lead to misleading intuitions in the unstable case.

Proof of Theorem 6.3.2.2. Let \(C_0, C_1,\) and \(C_2\) denote the fibers of the coCartesian fibration \(p_0 : \mathcal{C} \to \Delta^2\), so that \(p_0\) determines functors \(F : C_0 \to C_1\) and \(G : C_1 \to C_2\). Fix a nonempty finite set \(I\). The construction of Notation 6.3.2.11 determines a functor \(\theta : N(\text{Part}(I)) \to \text{Fun}(C_0^I, C_2^I)\). We wish to show that for every sequence of objects \(\vec{C} = \{C_i \in \mathcal{C}_0\}_{i \in I}\), the induced map
\[
\theta(\emptyset)(\vec{C}) \to \lim_{P \in \text{Part}(I)} \theta(P)(\vec{C})
\]
is an equivalence in \(\mathcal{C}_2\). Unwinding the definitions, we see that \(\theta\) carries a nonempty chain of equivalence relations \(P = (E_1 \subset E_2 \subset \cdots \subset E_k)\) to the functor \(\theta(P)\) given by the formula
\[
\theta(P)(\{C_i\}) = G(\prod_{j \in I/E_i} F(\prod_{j \in I} C_j)).
\]
In particular, \(\theta^0 = \theta|N(\text{Part}^0(I))\) factors as a composition
\[
N(\text{Part}^0(I)) \overset{\phi}{\to} N(\text{Equiv}(I))^{\text{op}} \overset{\psi}{\to} \text{Fun}(C_0^I, C_2^I),
\]
where \(\phi\) carries a chain of equivalence relations \((E_1 \subset E_2 \subset \cdots \subset E_k)\) to the equivalence relation \(E_1\). We claim that \(\phi\) is right cofinal. Since \(\phi\) is a coCartesian fibration, it suffices to show that the fibers of \(\phi\) are weakly contractible (Lemma T.4.1.3.2). This is clear, since each of these fibers has both an initial object. We are therefore reduced to proving that the canonical map
\[
\theta(\emptyset)(\vec{C}) \to \lim_{E \in \text{Equiv}(I)} \psi(E)(\{C_i\})
\]
is an equivalence. Note that \(N(\text{Equiv}(I))\) has a final object, given by the indiscrete equivalence relation \(E_\top\) (such that \(iE_\top j\) for all \(i, j \in I\)). We are therefore reduced to proving that the natural transformation \(\theta(\emptyset) \to \psi(E_\top)\) is an equivalence of functors from \(C_0^I\) to \(C_2^I\), which follows immediately from the definitions. \(

6.3.3 Derivatives of the Identity Functor

Let \(\mathcal{C}\) be a compactly generated pointed \(\infty\)-category. Conjecture 6.3.0.7 asserts in particular that the derivatives \(\{\partial_n(\text{id}_\mathcal{C})\}_{n \geq 1}\) can be regarded as an algebra object in the \(\infty\)-category of symmetric sequences.
Let us consider the special case where \( \mathcal{C} = \mathcal{S} \) is the \( \infty \)-category of pointed spaces, so that \( \mathbf{Sp}(\mathcal{C}) \simeq \mathbf{Sp} \) is the \( \infty \)-category of spectra. Let \( S \in \mathbf{Sp}(\mathcal{S}) \simeq \mathbf{Sp} \) denote the sphere spectrum. Repeatedly applying Corollary 1.4.4.6, we see that each of the functors \( \partial_n(\id) \) is determined by the single object \( (\partial_n F)(S, S, \ldots, S) \in \mathbf{Sp}(\mathcal{C}) \), which we will denote by \( \partial_n(F) \). In the special case where \( \mathcal{C} = \mathcal{S} \), we can identify each \( \partial_n(F) \) with a spectrum, so that \( \{ \partial_n(F) \}_{n \geq 1} \) can be viewed as a symmetric sequence of spectra.

Let \( \id : \mathcal{S} \to \mathcal{S} \) be the identity functor. Conjecture 6.3.0.7 implies in particular that \( \{ \partial_n(\id) \}_{n \geq 1} \) can be regarded as an algebra with respect to the composition product on symmetric sequences of spectra. In other words, it implies that can regard \( \{ \partial_n(\id) \}_{n \geq 1} \) as an \textit{operad} in the category of spectra, in that it is equipped with composition maps

\[
\partial_m(\id) \otimes \partial_{n_1}(\id) \otimes \cdots \otimes \partial_{n_m}(\id) \to \partial_{n_1 + \cdots + n_m}(\id)
\]
satisfying suitable associative laws. A structure of this type was constructed by Ching, who showed that \( \{ \partial_n(\id) \}_{n \geq 1} \) can be regarded as a homotopy-theoretic analogue of the Lie operad (see [29]). Ching’s work built upon earlier results of Arone and Mahowald, who gave an explicit description of the spectra \( \partial_n(\id) \) as the Spanier-Whitehead dual of a certain partition complex. To recall their result, we need to introduce a bit of notation.

**Definition 6.3.3.1.** Let \( I \) be a nonempty finite set. We let \( \text{Equiv}(I) \) denote the collection of all equivalence relations on \( I \). We will regard \( \text{Equiv}(I) \) as a partially ordered set, where \( E \leq E' \) if \( xEy \) implies \( xE'y \).

We let \( E_\uparrow \) denote the trivial equivalence relation on \( I \) (so that \( xE_\uparrow y \) for all \( x, y \in S \) and \( E_\perp \) the discrete equivalence relation on \( I \) (so that \( xE_\perp y \) if and only if \( x = y \)). Then \( E_\uparrow \) and \( E_\perp \) are the greatest and smallest elements of \( \text{Equiv}(I) \), respectively. We set

\[
\text{Equiv}^+(I) = \text{Equiv}(I) - \{E_\downarrow\} \quad \text{Equiv}^-(I) = \text{Equiv}(I) - \{E_\uparrow\} \quad \text{Equiv}^\pm(I) = \text{Equiv}^+(I) \cap \text{Equiv}^-(I) = \text{Equiv}(I) - \{E_\uparrow, E_\perp\}.
\]

**Notation 6.3.3.2.** Let \( S \in \mathbf{Sp} \) denote the sphere spectrum. Since the \( \infty \)-category \( \mathbf{Sp}^{op} \) admits small colimits, Theorem T.5.1.5.6 implies that there is an essentially unique functor \( F : \mathcal{S} \to \mathbf{Sp}^{op} \) which preserves small colimits and satisfies \( F(*) = S \). If \( X \) is a space, we will denote the spectrum \( F(X) \) by \( S^X \), and refer to it as the Spanier-Whitehead dual of \( X \).

More generally, if \( K \) is any simplicial set, we let \( S^K \) denote the Spanier-Whitehead dual of a fibrant replacement for \( K \).

**Theorem 6.3.3.3** (Arone-Mahowald). Let \( n \geq 1 \) be a positive integer and set \( I = \{1, \ldots, n\} \). Then there is a fiber sequence of spectra

\[
\partial_n(\id) \to S^{N(\text{Equiv}(I))} \to S^{N(\text{Equiv}^+(I))} \times_{S^{N(\text{Equiv}^\pm(I))}} S^{N(\text{Equiv}^-(I))}.
\]

**Remark 6.3.3.4.** The fiber sequence of Theorem 6.3.3.3 is equivariant with respect to the action of the symmetric group \( \Sigma_n \).

**Remark 6.3.3.5.** If \( n = 1 \), then the partially ordered sets \( \text{Equiv}^+(I) \), \( \text{Equiv}^-(I) \), and \( \text{Equiv}^\pm(I) \) are empty. In this case, Theorem 6.3.3.3 asserts the existence of an equivalence \( \partial_1(\id) \simeq \mathcal{S} \), which can be deduced directly from Example 6.2.1.4. If \( n > 1 \), then the simplicial sets \( N(\text{Equiv}(I)) \), \( N(\text{Equiv}^+(I)) \), and \( N(\text{Equiv}^-(I)) \) are weakly contractible. In this case, Theorem 6.3.3.3 asserts the existence of an equivalence

\[
\partial_n(\id) \to \Omega \text{fib}(S \to S^{N(\text{Equiv}^\pm(I))}).
\]

For the original proof of Theorem 6.3.3.3, we refer the reader to [3]. In this section, we will give a rather different proof which is based on the exactness properties of the construction \( F \to \tilde{\partial}(F) \), where \( F : \mathcal{C}_1 \times \cdots \times \mathcal{C}_n \to \mathcal{D} \) is a functor of several variables. Recall that the differential of \( F \) is given by \( P_1 \text{cored}(F) \), where \( \text{cored}(F) \) denotes the coreduction of \( F \) (Construction 6.2.3.6) and \( \tilde{\partial} = (1, \ldots, 1) \) (see
Example 6.2.3.5). The construction $F \mapsto P_1 F$ is preserves finite limits (Theorem 6.1.1.10), but the formation of coreductions generally does not. The key to our proof of Theorem 6.3.3.3 will be to show that, nevertheless, the construction $F \mapsto \partial F$ commutes with certain very special finite limits. Before we can formulate a precise result, we need to introduce some notation.

**Notation 6.3.3.6.** Let $\mathcal{C}$ be a pointed $\infty$-category which admits finite limits, let $K$ be a finite simplicial set, and let $U : K^\circ \to \mathcal{C}$ be a diagram. Let $v$ denote the cone point of $K^\circ$. We let $\text{tfib}(U)$ denote the fiber of the induced map

$$U(v) \to \varprojlim(U[K]).$$

We will refer to $\text{tfib}(U)$ as the total fiber of the diagram $U$.

**Remark 6.3.3.7.** In the situation of Notation 6.3.3.6, if $U$ is a limit diagram, then $\text{tfib}(U)$ is a final object of $\mathcal{C}$. The converse holds if the $\infty$-category $\mathcal{C}$ is stable.

**Remark 6.3.3.8.** Let $\mathcal{C}$ and $\mathcal{D}$ be pointed $\infty$-categories which admit finite limits, and let $F : \mathcal{C} \to \mathcal{D}$ be a functor which preserves zero objects. For every finite diagram $U : K^\circ \to \mathcal{C}$, there is a canonical map $F(\text{tfib}(U)) \to \text{tfib}(F \circ U)$. If $F$ is left exact, then this map is an equivalence.

**Remark 6.3.3.9.** Let $\{\mathcal{C}_s\}_{s \in S}$ be a finite collection of pointed $\infty$-categories which admit finite limits, let $\{K_s\}_{s \in S}$ be a finite collection of finite simplicial sets, and suppose we are given diagrams $U_s : K_s^\circ \to \mathcal{C}_s$. Let $\mathcal{D}$ be a pointed $\infty$-category which admits finite limits, and let $G : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}$ be a functor which is left exact in each variable. Then $G(\{\text{tfib}(U_s)\}_{s \in S})$ can be identified with the total fiber of the diagram

$$\prod_{s \in S} K_s^\circ \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}.$$

**Example 6.3.3.10.** In the situation of Notation 6.3.3.6, suppose that $K = \Delta^0$, so that a map $U : K^\circ \to \mathcal{C}$ can be identified with a morphism $f$ in $\mathcal{C}$. We then have a canonical equivalence $\text{tfib}(U) \cong \text{fib}(f)$.

**Example 6.3.3.11.** Let $\{\mathcal{C}_s\}_{s \in S}$ be a finite collection of $\infty$-categories which admit final objects, let $\mathcal{D}$ be a pointed $\infty$-category which admits finite limits, and let $F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}$ be a functor. Then the reduction $\text{Red}(F)$ introduced in Construction 6.1.3.15 is given by the total fiber of the diagram of functors $\{F_E\}_{T \subseteq S}$.

Our next goal is to construct a variant of Example 6.3.3.11. More precisely, we will show that if $F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}$ is a functor which carries final objects of $\prod_{s \in S} \mathcal{C}_s$ to final objects of $\mathcal{D}$, then the reduction $\text{Red}(F)$ has a different description as the total fiber of a diagram of functors (which is better behaved with respect to differentiation).

**Construction 6.3.3.12.** Let $\{\mathcal{C}_s\}_{s \in S}$ be a nonempty finite collection of $\infty$-categories which admit final objects $s \in \mathcal{C}_s$. Let $F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}$ be a functor, where $\mathcal{D}$ is an $\infty$-category which admits finite products. For every equivalence relation $E$ on the set $S$, we let $F^E : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}$ denote the functor given by the formula

$$F^E(\{X_s\}_{s \in S}) = \prod_{T \subseteq S \setminus E} F(\{X_s\}_{s \in S})$$

where

$$X_s^T = \begin{cases} X_s & \text{if } s \in T \\ s & \text{if } s \notin T. \end{cases}$$

It will be convenient to have a more formal construction of the collection of functors $\{F^E\}_{E \subseteq \text{Equiv}(S)}$. For this, we define a partially ordered set $\text{Equiv}(S)$ as follows:

(a) The objects of $\text{Equiv}(S)$ are pairs $(T, E)$, where $T \subseteq S$ and $E$ is an equivalence relation on $T$.

(b) We have $(T, E) \leq (T', E')$ if and only if $T \subseteq T'$ and $xEy$ implies $xE'y$ for $x, y \in T$. 

Let us identify $\text{Equiv}(S)$ with the partially ordered subset of $\overline{\text{Equiv}}(S)$ consisting of those pairs $(T, E)$ where $T = S$, and let $\overline{\text{Equiv}}_0(S)$ denote the subset of $\text{Equiv}(S)$ consisting of those pairs $(T, E)$ where $E$ is a trivial equivalence relation on $T$.

Now let $F : \prod_{s \in S} C_s \to D$ be as above, and for $T \subseteq S$ let $F^T$ be the functor defined in Construction 6.1.3.15. The construction $(T, E) \mapsto F^{S-T}$ determines a functor $N(\overline{\text{Equiv}}_0(S))^\text{op} \to \text{Fun}(\prod_s C_s, D)$. This functor admits a right Kan extension $N(\text{Equiv}(S))^\text{op} \to \text{Fun}(\prod_s C_s, D)$, which we will denote by $(T, E) \mapsto F^{(T,E)}$. When $T = S$, we will denote $F^{(T,E)}$ simply by $F^E$.

Note that $F^E \simeq \prod_{T \subseteq S / E} F^T$ agrees with the functor defined informally above.

**Proposition 6.3.3.13.** Let $S$ be a nonempty finite set, let $F : \prod_{s \in S} C_s \to D$ be a functor between $\infty$-categories. Assume that each $C_s$ has a final object $*_{s}$, that $D$ is pointed and admits finite limits, and that $F(*_{s})$ is a final object of $D$. Let $H$ denote the total fiber of the diagram $\{F^E\}_{E \in \text{Equiv}(S)}$. Then:

(a) The functor $H : \prod_{s \in S} C_s \to D$ is reduced.

(b) Let $G : \prod_{s \in S} C_s \to D$ be any reduced functor. Then the canonical map $H \to F^{*_{s}} \simeq F$ induces a homotopy equivalence

$$\text{Map}_\text{Fun}(\prod_{s \in S} C_s, D)(G, H) \to \text{Map}_\text{Fun}(\prod_{s \in S} C_s, D)(G, F).$$

Consequently, we have a canonical equivalence $H \simeq \text{Red}(F)$.

**Proof.** We first prove (a). We will assume that $S$ has more than one element (otherwise $H = F$ and the result is obvious). Fix an element $t \in S$ and choose a sequence of objects $\{X_s \in C_s\}$ such that $X_t = *_{t}$. We will prove that the canonical map $F(\{X_s\}) \to \lim_{E \in \text{Equiv}^+(S)} F^E(\{X_s\})$ is an equivalence. Let $U \subseteq \text{Equiv}(S)$ denote the subset consisting of those equivalence relations $E$ on $S$ such that, if $s \in t$, then $s = t$ (that is, the set $\{t\}$ is an equivalence class with respect to $E$). Note that the inclusion $N(U) \to N(\text{Equiv}(S))$ admits a right adjoint, which we will denote by $E \mapsto E'$. Using our assumption that $X_t = *_{t}$ and that $F(\{*_{s}\})$ is a final object of $D$, we deduce that the canonical map $F^{E}(\{X_s\}) \to F^{E'}(\{X_s\})$ is an equivalence for every equivalence relation $E \in \text{Equiv}(S)$. Let $U^+ = U \cap \text{Equiv}^+(S)$. The preceding argument shows that the diagram $\{F^E(\{X_s\})\}_{E \in \text{Equiv}^+(S)}$ is a right Kan extension of its restriction to $\{F^{E}(\{X_s\})\}_{E \in U^+}$. Note that $U^+$ has a largest element (given by the equivalence $E_0$ relation corresponding to the partition $S = \{t\} \cup (S - \{t\})$), so that $\lim_{E \in \text{Equiv}^+(S)} F^E(\{X_s\})$ is given by $F^{E_0}(\{X_s\})$. It now suffices to observe that the map $F(\{X_s\}) \to F^{E_0}(\{X_s\})$ is an equivalence.

To prove (b), it will suffice to show that the space

$$\text{Map}_\text{Fun}(\prod_{s \in S} C_s, D)(G, \lim_{E \in \text{Equiv}^+(S)} F^E)$$

is contractible. In fact, we claim that the mapping space

$$\text{Map}_\text{Fun}(\prod_{s \in S} C_s, D)(G, F^E)$$

is contractible for every nontrivial equivalence relation $E$ on $S$. Let $S_1, \ldots, S_k$ denote the equivalence classes with respect to $\sim$, so that $F^E = \prod_{1 \leq i \leq k} F^{S_i}$ (where $F^{S_i}$ is defined as in Construction 6.1.3.15). It will therefore suffice to show that each of the mapping spaces $\text{Map}_\text{Fun}(\prod_{s \in S} C_s, D)(G, F^{S_i})$ is contractible. Let $\mathcal{E} \subseteq \prod_{s \in S} C_s$ be the full subcategory spanned by those sequences $\{Y_s\}_{s \in S}$ such that $Y_s$ is a final object of $C_s$ for $s \notin S_i$. Then $F^{S_i}$ is a right Kan extension of its restriction to $\mathcal{E}$. It will therefore suffice to show that $\text{Map}_\text{Fun}(\mathcal{E}, D)(G|\mathcal{E}, F^{S_i}|\mathcal{E})$ is contractible. This is clear, since $G$ carries each object of $\mathcal{E}$ to a zero object of $D$.

The main ingredient in our proof of Theorem 6.3.3.3 is the following assertion:
6.3. THE CHAIN RULE

**Theorem 6.3.3.14.** Let \( \{C_s\}_{s \in S} \) be a nonempty finite collection of pointed \( \infty \)-categories which admit finite colimits. For each functor \( F : \prod_{s \in S} C_s \to S_* \), let \( DF \) denote a differential of \( F \) (see Definition 6.2.3.1 and Proposition 6.2.3.13). Suppose that \( F : \prod_{s \in S} C_s \to S_* \) is a functor such that \( F(\{*_s\}) \) is contractible, so that Proposition 6.3.3.13 furnishes an equivalence \( \theta : \text{Red}(F) \simeq \text{tfib}(FE)_{E \in \text{Equiv}(S)} \). Then \( \theta \) induces an equivalence \( D \text{Red}(F) \simeq \text{tfib}(D^{FE})_{E \in \text{Equiv}(S)} \).

**Example 6.3.3.15.** In the situation of Theorem 6.3.3.14, suppose that \( S = \{0,1\} \) and let \(*\) denote the zero object of both \( C_0 \) and \( C_1 \). Theorem 6.3.3.14 asserts that, if \( F : C_0 \times C_1 \to S_* \) is a functor such that \( F(*,*) \) is contractible and we define \( G : C_0 \times C_1 \to S_* \) by the formula \( G(C,D) = F(C,*) \times F(*,D) \), then the fiber sequence

\[
\text{Red}(F) \to F \to G
\]

induces a fiber sequence of differentials

\[
D \text{Red}(F) \to DF \to DG.
\]

Combining Theorem 6.3.3.14 with Corollary 6.2.3.22, we obtain the following result:

**Corollary 6.3.3.16.** Let \( \{C_s\}_{s \in S} \) be a nonempty finite collection of pointed differentiable \( \infty \)-categories which admit finite colimits, and let \( F : \prod_{s \in S} C_s \to S_* \) be a functor which preserves final objects and sequential colimits. Then the equivalence \( \text{Red}(F) \simeq \text{tfib}(FE)_{E \in \text{Equiv}(S)} \) induces an equivalence \( \partial \text{Red}(F) \simeq \text{tfib}(\partial FE)_{E \in \text{Equiv}(S)} \) of functors from \( \prod_{s \in S} \text{Sp}(C_s) \to \text{Sp}(\mathbb{D}) \).

The proof of Theorem 6.3.3.14 is rather elaborate, and will be given in §6.3.4. We conclude this section by showing how Theorem 6.3.3.3 can be deduced from Theorem 6.3.3.14.

**Proof of Theorem 6.3.3.3.** Let \( \text{id} : S_* \to S_* \) be the identity functor; we wish to describe the spectrum \( \partial_n(\text{id}) \) or equivalently the functor \( \partial_n(\text{id}) : \text{Sp}^n \to \text{Sp} \). Let \( F : S_*^n \to S_* \) be the functor given by \( F(X_1,\ldots,X_n) = X_1 \amalg \cdots \amalg X_n \), so that the functor \( \partial_n(\text{id}) \) is given by the derivative of \( \text{Red}(F) \). Set \( T = \{1,\ldots,n\} \). Using Corollary 6.3.3.16, we obtain an equivalence of functors \( \alpha : \partial_n(\text{id}) \simeq \text{tfib}(\partial FE)_{E \in \text{Equiv}(T)} \). Since the product functor on \( S_* \) preserves pushouts in each variable, it follows from Example 6.2.3.10 that \( \text{cored}(FE) \) is trivial for \( E \neq E_\perp \). Moreover, \( FE_\perp \) is given by the formula \( FE_\perp(X_1,\ldots,X_n) = X_1 \times \cdots \times X_n \), so that \( \text{cored}(FE_\perp) \) is the iterated smash product functor \( \wedge : S_*^n \to S_* \) and therefore \( \partial FE_\perp : \text{Sp}^n \to \text{Sp} \) is also given by the iterated smash product (see Example 6.2.3.28). In particular, we have \( \partial FE(S,S,\ldots,S) \simeq G'(E) \), where \( G' : \text{N(Equiv}(T))^\text{op} \to \text{Sp} \) denote the functor given by the formula

\[
G'(E) = \begin{cases} S & \text{if } E = E_\perp \\ 0 & \text{otherwise.} \end{cases}
\]

Evaluating \( \alpha \) on the sphere spectrum, we obtain an equivalence of spectra \( \partial_n(\text{id}) \simeq \text{tfib}(G') \).

Let \( G : \text{N(Equiv}(T))^\text{op} \to \text{Sp} \) be the constant functor taking the value \( S \), and let \( G'' : \text{N(Equiv}(T))^\text{op} \to \text{Sp} \) be given by \( G''(E) = \begin{cases} 0 & \text{if } E = E_\perp \\ S & \text{otherwise.} \end{cases} \) so that we have a fiber sequence of functors

\[
G' \to G \to G''
\]

and therefore a fiber sequence of spectra

\[
\partial_n(\text{id}) \to \text{tfib}(G) \to \text{tfib}(G'') \to \text{tfib}(G''').
\]

Unwinding the definitions, we have equivalences

\[
\text{tfib}(G) = \text{fib}(\lim(G) \to \lim(G|\text{N(Equiv}^+(T))) \quad \text{tfib}(G'') = \text{fib}(\lim(G'') \to \lim(G''|\text{N(Equiv}^+(T)))).
\]
Note that $G''$ is a right Kan extension of $G|\text{N}(\text{Equiv}^-(T))$, so that
\[ \text{tfib}(G'') \simeq \text{fib}(\lim(G|\text{N}(\text{Equiv}^-(T))) \to \lim(G|\text{N}(\text{Equiv}^+(T))). \]
We may therefore identify $\partial_n(id)$ with the total fiber of the diagram of spectra
\[
\begin{array}{ccc}
\lim(G) & \rightarrow & \lim(G|\text{N}(\text{Equiv}^+(T))) \\
\downarrow & & \downarrow \\
\lim(G|\text{N}(\text{Equiv}^-(T))) & \rightarrow & \lim(G|\text{N}(\text{Equiv}^-(T))).
\end{array}
\]
which is the fiber of the canonical map
\[ S^N(\text{Equiv}(T)) \rightarrow S^N(\text{Equiv}^+(T)) \times S^N(\text{Equiv}^-(T)). \]

\[ \square \]

6.3.4 Differentiation and Reduction

Let $\{\mathcal{C}_s\}_{s \in S}$ be a nonempty finite collection of pointed $\infty$-categories which admit finite colimits, and let $F : \prod_{s \in S} \mathcal{C}_s \to S_*$ be a functor which preserves final objects. Our goal in this section is to prove Theorem 6.3.3.14, which asserts that the canonical map
\[ d\text{Red}(F) \to \text{tfib}\{dF_E\}_{E \in \text{Equiv}(S)} \]
is an equivalence of functors from $\prod_{s \in S} \mathcal{C}_s \to S_*$ (here $dG$ denotes the differential of a functor $G$). We can outline our strategy as follows:

(a) Let $\mathcal{C} = \prod_{s \in S} \mathcal{C}_s$. We will show that any functor $F : \mathcal{C} \to S_*$ can be “approximated” by products of homogeneous functors (Proposition 6.3.4.4).

(b) We show that any homogeneous functor from $\mathcal{C}$ to $\mathcal{D}$ is a product of functors which are homogeneous in each variable (Proposition 6.3.4.11).

(c) Using (a) and (b), we are reduced to proving Theorem 6.3.3.14 for (products of) functors which are homogeneous in each variable. In this case, we will obtain the desired result by combining the classification of homogeneous functors given in §6.1.4 with an analysis of the partially ordered set $\text{Equiv}(S)$ of equivalence relations on $S$.

To carry out step (a), we need to introduce some terminology.

**Definition 6.3.4.1.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object and let $\mathcal{D}$ be a differentiable $\infty$-category. We will say that a natural transformation $\alpha : F \to G$ of functors $F, G : \mathcal{C} \to \mathcal{D}$ is a jet equivalence if $\alpha$ induces an equivalence $P_n F \to P_n G$ for every integer $n$.

**Remark 6.3.4.2.** Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits and has a final object, let $\mathcal{D}$ be a differentiable $\infty$-category, and suppose we are given a pullback diagram
\[
\begin{array}{ccc}
F & \xrightarrow{\alpha} & F' \\
\downarrow & & \downarrow \\
G & \xrightarrow{\beta} & G'
\end{array}
\]
in the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$. If $\beta$ is a jet equivalence, then $\alpha$ is also a jet equivalence. This follows from the fact that each of the functors $P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D})$ is left exact (Remark 6.1.1.29).
Remark 6.3.4.3. Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object and let \( \mathcal{D} \) be a differentiable \( \infty \)-category. Assume that \( \mathcal{D} \) admits \( K \)-indexed colimits, for some simplicial set \( K \). Then the collection of jet equivalences is closed under \( K \)-indexed colimits (when regarded as a full subcategory of \( \text{Fun}(\Delta^1, \text{Fun}(\mathcal{C}, \mathcal{D})) \)). This follows immediately from the observation that \( P_n : \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D}) \) is a localization functor.

The main ingredient in our proof of Theorem 6.3.3.14 is the following general approximation result:

**Proposition 6.3.4.4.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, let \( F : \mathcal{C} \to S_* \) be a reduced functor, and let \( n \geq 0 \) be an integer. Then there exists a simplicial object \( F_* \) of \( \text{Fun}(\mathcal{C}, S_*) \) and a jet equivalence \( \alpha : F_* \to P_n F \) satisfying the following condition:

\[
(\ast_n) \quad \text{For each integer } p \geq 0, \text{ the functor } F_p \text{ can be written as a finite product } F_p \simeq \prod \alpha F_{p,\alpha}, \text{ each each } F_{p,\alpha} : \mathcal{C} \to S_\ast \text{ is } k_\alpha\text{-homogeneous for some } 1 \leq k_\alpha \leq n.
\]

The proof of Proposition 6.3.4.4 will require some preliminaries.

**Lemma 6.3.4.5.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object, let \( \mathcal{D} \) be a pointed differentiable \( \infty \)-category, and let \( \alpha : F \to G \) be a natural transformation between functors \( F, G : \mathcal{C} \to \mathcal{D} \). Assume that:

(i) The map \( \alpha \) induces an equivalence \( F(\ast) \to G(\ast) \), where \( \ast \) denotes the final object of \( \mathcal{C} \).

(ii) There exists an integer \( k \) such that \( \alpha \) induces an equivalence of functors \( \Omega^k(F) \to \Omega^k(G) \).

Then \( \alpha \) is a jet equivalence.

**Proof.** We will prove that \( P_n(\alpha) \) is an equivalence using induction on \( n \). If \( n = 0 \), the desired result follows from (i). If \( n > 0 \), we use Theorem 6.1.2.4 to construct a map of fiber sequences

\[
\begin{array}{ccc}
P_n F & \to & P_{n-1} F \to RF \\
\downarrow P_n(\alpha) & & \downarrow R(\alpha) \\
P_n G & \to & P_{n-1} G \to RG.
\end{array}
\]

Since \( P_{n-1}(\alpha) \) is an equivalence by the inductive hypothesis, it will suffice to show that \( R(\alpha) \) is an equivalence. Because the functor \( R \) is left exact, condition (ii) implies that \( R(\alpha) \) induces an equivalence \( \Omega^k RF \to \Omega^k RG \) for some integer \( k \). Since the \( \infty \)-category \( \text{Homog}^n(\mathcal{C}, \mathcal{D}) \) is stable (Corollary 6.1.2.8), this implies that \( R(\alpha) \) is itself an equivalence.

**Lemma 6.3.4.6.** Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite colimits and has a final object. Let \( n \geq 0 \), and let \( U : \text{Fun}(\text{N}(\Delta)^{\text{op}}, \text{Fun}_n(\mathcal{C}, S_*)) \to \text{Fun}_n(\mathcal{C}, S_*) \) be the functor given by the formula \( U(F_*) = P_n|F_*| \). Then \( U \) preserves finite limits.

**Proof.** Since it is clear that \( U \) preserves final objects, it will suffice to show that \( U \) preserves pullback squares (Corollary T.4.4.2.5). Let \( \tau_{\geq 1} : S_* \to S_* \) be the functor which assigns to each pointed space \( X \) the connected component of its base point (so that we have a fiber sequence \( \tau_{\geq 1}X \to X \to \pi_0X \)). For every functor \( F : \mathcal{C} \to S_* \), let \( F^\circ \) denote the composite functor

\[
\mathcal{C} \xrightarrow{F} S_* \xrightarrow{\tau_{\geq 1}} S_*.
\]

There is an evident natural transformation \( F^\circ \to F \). According to Lemma 6.3.4.5, this natural transformation is a jet equivalence whenever \( F \) is reduced (or, more generally, whenever \( F \) carries the final object of \( \mathcal{C} \) to a connected space). If we are given a simplicial object \( F_* \) in \( \text{Fun}_n(\mathcal{C}, \mathcal{D}) \), then we obtain a new simplicial object \( F^\circ_* \), and Remark 6.3.4.3 implies that the induced map \( |F^\circ_*| \to |F_*| \) is also a jet equivalence, and therefore induces an equivalence \( U(F^\circ_*) \to U(F_*) \).
Suppose now that we are given a pullback diagram \( \sigma : \)

\[
\begin{array}{c}
F \rightarrow \quad \rightarrow \\
\downarrow \quad \downarrow \\
G \rightarrow \quad \rightarrow
\end{array}
\]

of simplicial objects of \( \text{Fun}_*(\mathcal{C}, \mathcal{D}) \). We would like to show that \( U(\sigma) \) is also a pullback diagram. In view of the above arguments, it will suffice to show that \( U \) carries the diagram \( \sigma' : \)

\[
\begin{array}{c}
F' \rightarrow \quad \rightarrow \\
\downarrow \quad \downarrow \\
G' \rightarrow \quad \rightarrow
\end{array}
\]

to a pullback diagram in \( \text{Fun}_*(\mathcal{C}, S_*) \). Let \( H_* \) be the simplicial functor given by the fiber product \( F^o_\bullet \times_{G^o_\bullet} G^o_\bullet \). For every integer \( k \geq 0 \) and every object \( X \in \mathcal{C} \), we have a pullback diagram

\[
\begin{array}{c}
F^o_k(X) \rightarrow \quad \rightarrow \\
\downarrow \quad \downarrow \\
\pi_0 F_k(X) \rightarrow \quad \rightarrow \\
\pi_0 F^o_k(X) \times_{\pi_0 G^o_k(X)} \pi_0 G_k(X)
\end{array}
\]

so that the canonical map \( F^o_k(X) \rightarrow H_k(X) \) has nonempty, discrete homotopy fibers (that is, it is a covering map). Using Lemma 6.3.4.5, we deduce that the map \( F^o_k \rightarrow H_k \) is a jet equivalence, so that Remark 6.3.4.3 implies that \( U(F^o_\bullet) \rightarrow U(H_\bullet) \) is an equivalence. It will therefore suffice to show that the pullback diagram

\[
\begin{array}{c}
H \rightarrow \quad \rightarrow \\
\downarrow \quad \downarrow \\
G \rightarrow \quad \rightarrow
\end{array}
\]

remains a pullback diagram after applying the functor \( U \). Because \( P_n \) is left exact (Remark 6.1.1.29), we are reduced to proving that the diagram

\[
\begin{array}{c}
|H_*| \rightarrow \quad \rightarrow \\
\downarrow \quad \downarrow \\
|G_*| \rightarrow \quad \rightarrow
\end{array}
\]

is a pullback square of functors. This is equivalent to the assertion that for every object \( X \in \mathcal{C} \), the diagram

\[
\begin{array}{c}
|H_*(X)| \rightarrow \quad \rightarrow \\
\downarrow \quad \downarrow \\
|G_*(X)| \rightarrow \quad \rightarrow
\end{array}
\]

is a pullback square of spaces. This follows from Lemma 5.5.6.17 (note that each \( G^o_k(X) \) is connected, by construction). \( \square \)
6.3. THE CHAIN RULE

Proof of Proposition 6.3.4.4. Let $G : \mathcal{C} \to S_*$ denote the constant functor taking the value $\Delta^0$, and let $G_\bullet$ be the constant simplicial object of $\text{Fun}(\mathcal{C}, S_*)$ taking the value $G$. We proceed by induction on $n$. When $n = 0$, we can take $F_\bullet = G_\bullet$. Let us therefore assume that $n > 0$. By the inductive hypothesis, we can choose a jet equivalence $\alpha : |F_\bullet| \to P_{n-1}F$ satisfying condition $(\ast_{n-1})$. Choose a natural transformation $u : G_\bullet \to F_\bullet$, and let $F_{\bullet,u}$ be the Čech nerve of $u$. For every integer $p \geq 0$, we have an augmentation map

$$v_p : \lim_{[q]} F_{p,q} \to F_p$$

which exhibits $\lim_{[\mathcal{C}],q} F_{p,q}(X)$ as the base point component of $F_p(X)$, for every object $X \in \mathcal{C}$. Using Lemma 6.3.4.5, we deduce that $v_p$ is a jet equivalence. It follows that the composite map

$$P_n(\lim_{[p]} F_{p,q}) \to P_n|F_\bullet| \simeq P_{n-1}F$$

is also a jet equivalence. Define a simplicial object $F'_\bullet$ of $\text{Fun}(\mathcal{C}, S_*)$ by the formula $F'_p = F_{p,p}$. Since the $\infty$-category $\text{N}(\Delta)^op$ is sifted, we conclude that the map $|F'_\bullet| \to P_{n-1}F$ is a jet equivalence.

Theorem 6.1.2.4 supplies a fiber sequence of functors

$$P_nF \to P_{n-1}F \to RF,$$

where $R$ is $n$-homogeneous, and let $F''_\bullet$ denote the simplicial object of $\text{Fun}(\mathcal{C}, S_*)$ whose $p$th term is given by the fiber of the composite map

$$F'_p \to P_{n-1}F \to RF.$$  

We claim that the evident map $\beta : |F''_\bullet| \to P_nF$ satisfies our requirements. Since colimits in $S$ are universal, we have a pullback diagram

$$\begin{array}{ccc}
|F''_\bullet| & \longrightarrow & |F'_\bullet| \\
\downarrow{\beta} & & \downarrow{\gamma} \\
P_nF & \longrightarrow & P_{n-1}F.
\end{array}$$

For every integer $p \geq 0$, the map $F'_p \to P_{n-1}F \to R$ factors through $F'_0 \simeq G$ and is therefore nullhomotopic. We therefore have an equivalence

$$F''_p \simeq \Omega(RF) \times F'_p \simeq \Omega(RF) \times F_{p,p} \simeq \Omega(RF) \times \Omega(F_p)^p.$$  

Because the simplicial object $F'_\bullet$ satisfies $(\ast_{n-1})$ and $R$ is $n$-homogeneous, we deduce that $F''_\bullet$ satisfies $(\ast_n)$.

To apply Proposition 6.3.4.4 in our context, we need to know something about the classification of homogeneous functors with domain $\prod_{s \in S} \mathcal{C}_s$. For this, we need to generalize some of the results of §6.1.4 to the multivariate case. We begin by proving a generalization of Proposition 6.1.3.10.

**Proposition 6.3.4.7.** Let $\{\mathcal{C}_s\}_{s \in S}$ be a nonempty finite collection of pointed $\infty$-categories which admit finite colimits, let $\mathcal{C} = \prod_{s \in S} \mathcal{C}_s$, and let $\mathcal{D}$ be a pointed differentiable $\infty$-category. Let $F : \prod_{s \in S} \mathcal{C}_s \to \mathcal{D}$ be a functor which is $n_s$-reduced in the $s$th argument. Then $F$ is $n$-reduced (when regarded as a functor from $\mathcal{C}$ to $\mathcal{D}$).

**Lemma 6.3.4.8.** Let $\mathcal{C}_0$ and $\mathcal{C}_1$ be $\infty$-categories which admit finite colimits and zero objects $*_0$ and $*_1$, let $\mathcal{C} = \mathcal{C}_0 \times \mathcal{C}_1$, and let $\mathcal{D}$ be an $\infty$-category which admits finite limits. Let $\phi_0$ denote the composite functor

$$\mathcal{C}_0 \simeq \mathcal{C}_0 \times \{*_1\} \to \mathcal{C}_0 \times \mathcal{C}_1 = \mathcal{C},$$

and define $\phi_1 : \mathcal{C}_1 \to \mathcal{C}$ similarly. Then composition with $\phi_0$ and $\phi_1$ induces an equivalence of $\infty$-categories

$$\theta : \text{Exc}_*(\mathcal{C}, \mathcal{D}) \to \text{Exc}_*(\mathcal{C}_0, \mathcal{D}) \times \text{Exc}_*(\mathcal{C}_1, \mathcal{D}).$$
Proof. Let \( \xi : \text{Exc}_s(\mathcal{E}_0, \mathcal{D}) \times \text{Exc}_s(\mathcal{E}_1, \mathcal{D}) \to \text{Exc}_s(\mathcal{E}_0 \times \mathcal{E}_1, \mathcal{D}) \) be the functor given by the formula

\[
\xi(F_0, F_1)(X, Y) = F_0(X) \times F_1(Y).
\]

It is easy to see that \( \xi \) is a homotopy inverse to \( \theta \).

\[\square\]

**Remark 6.3.4.9.** Let \( \{\mathcal{C}_s\}_{s \in S} \) be a nonempty finite collection of pointed \( \infty \)-categories which admit finite colimits, let \( \mathcal{E} = \prod_{s \in S} \mathcal{C}_s \), let \( \mathcal{D} \) be a pointed \( \infty \)-category which admits finite products. Let \( F : \mathcal{E} \to \mathcal{D} \) be a functor and let \( \text{cr}_n(F) : \mathcal{E}^n \to \mathcal{D} \) be its \( n \)th cross effect. Let \( d\text{cr}_n(F) \) denote the differential of \( \text{cr}_n(F) \) (where we regard \( \text{cr}_n(F) \) as a functor of \( n \) variables). The proof of Lemma 6.3.4.8 shows that \( d\text{cr}_n(F) \) can be written as a product of functors given by the composition

\[
\mathcal{E}^n \to \prod_{s \in S} \mathcal{E}_{s}^{m_s} \xrightarrow{d\text{cr}_n(F)} \mathcal{D}
\]

where \( \vec{n} \) varies over those tuples \( \{m_s\}_{s \in S} \) having sum \( n \) and the cross effects \( \text{cr}_n \) are defined as in Variant 6.1.3.21.

**Proof of Proposition 6.3.4.7.** If each \( n_s = 0 \), there is nothing to prove. Assume therefore that \( n_s > 0 \) for some \( s \in S \). Then \( F \) is 1-reduced as a functor of its \( s \)th argument, and therefore 1-reduced when regarded as a functor from \( \mathcal{C}_s \) to \( \mathcal{D} \). According to Proposition 6.1.3.24, it will suffice to show that for \( m < n \), the differential \( d\text{cr}_m(F) \) vanishes. Using Remark 6.3.4.9, we are reduced to proving that the functor

\[
d\text{cr}_m(F) : \prod_{s \in S} \mathcal{E}_{s}^{m_s} \to \mathcal{D}
\]

is trivial for every sequence \( \{m_s\}_{s \in S} \) satisfying \( \sum_{s \in S} m_s < n \). For such a sequence, we must have \( m_s < n_s \) for some \( s \). The desired result now follows by applying Remark 6.1.3.23 to \( F \), regarded as a functor from \( \mathcal{C}_s \) to \( \text{Fun}(\prod_{s \neq s} \mathcal{C}_s, \mathcal{D}) \).

\[\square\]

**Corollary 6.3.4.10.** Let \( \{\mathcal{C}_s\}_{s \in S} \) be a nonempty finite collection of \( \infty \)-categories which admit finite colimits and final objects, and let \( \mathcal{D} \) be a pointed differentiable \( \infty \)-category. For every collection of nonnegative integers \( \vec{n} = \{n_s\}_{s \in S} \), let \( \text{Hom}^\vec{n}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) spanned by those functors \( F \) which are \( n_s \)-homogeneous when regarded as a functor from \( \mathcal{C}_s \) to \( \text{Fun}(\prod_{s \neq s} \mathcal{C}_s, \mathcal{D}) \). Then \( \text{Hom}^\vec{n}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \subseteq \text{Hom}^\vec{\mathcal{C}}(\mathcal{C}, \mathcal{D}) \), where \( \mathcal{C} = \prod_{s \in S} \mathcal{C}_s \) and \( n = \sum_{s \in S} n_s \).

**Proof.** Combine Proposition 6.3.4.7 with Proposition 6.1.3.4.

\[\square\]

In the situation of Corollary 6.3.4.10, the \( \infty \)-category \( \text{Hom}^\vec{n}(\mathcal{C}, \mathcal{D}) \) can be reconstructed from the \( \infty \)-categories \( \text{Hom}^{\vec{\mathcal{C}}}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) as follows:

**Proposition 6.3.4.11.** Let \( \{\mathcal{C}_s\}_{s \in S} \) be a nonempty finite collection of pointed \( \infty \)-categories which admit finite colimits, let \( \mathcal{C} = \prod_{s \in S} \mathcal{C}_s \), let \( \mathcal{D} \) be a pointed differentiable \( \infty \)-category, and let \( n \geq 0 \) be an integer. For every collection of nonnegative integers \( \vec{n} = \{n_s\}_{s \in S} \), let \( |\vec{n}| = \sum_{s \in S} n_s \). Consider the functor

\[
\Phi : \prod_{|\vec{n}| = n} \text{Hom}^{\vec{\mathcal{C}}}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \to \text{Hom}^{\vec{n}}(\mathcal{C}, \mathcal{D})
\]

given by

\[
\Phi([F_{\vec{n}}]) = \prod_{|\vec{n}| = n} F_{\vec{n}}.
\]

Then \( \Phi \) is an equivalence of \( \infty \)-categories.
Lemma 6.3.4.12. Let $S$ be a finite set. Suppose we are given a finite collection of pointed $\infty$-categories $\{C_s\}_{s \in S}$ which admit finite colimits, and let $\mathcal{D}$ be an $\infty$-category which admits finite limits. Let $C = \prod_{s \in S} C_s$, and for each $s \in S$, let $\phi_s : C_s \to C$ be the functor given by the product of the identity map $id : C_s \to C_s$ with constant functor $C_s \to C_s$ carrying $C_s$ to a zero object of $C_s$ for $t \neq s$.

Fix an integer $n \geq 0$. For every collection of nonnegative integers $\vec{n} = \{n_s\}_{s \in S}$, set

$$e^{\vec{n}} = \prod_{s \in S} e^{n_s}, \quad e^{(\vec{n})} = \prod_{s \in S} e^{(n_s)},$$

where $e^{(n_s)}$ denotes the $n_s$th extended power of $C_s$ (see Notation 6.1.4.1). Let $\SymFun^{\vec{n}}(\mathcal{C}, \mathcal{D})$ denote the $\infty$-category $\Fun(e^{(\vec{n})}, \mathcal{D})$, and let $\SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\SymFun^{\vec{n}}(\mathcal{C}, \mathcal{D})$ spanned by those functors for which the underlying functor $\prod_{s \in S} e^{n_s} : \mathcal{C} \to \mathcal{D}$ is $1$-homogeneous in each variable. Let $U_{\vec{n}}$ denote the composite map

$$U_{\vec{n}} : e^{\vec{n}} \to \prod_{s \in S} e^{(n_s)} \to e^{(n)}.$$

Then the maps $U_{\vec{n}}$ induce an equivalence of $\infty$-categories

$$\Psi : \SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D}) \to \prod_{|\vec{n}| = n} \SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D}).$$

Proof. Using Lemma 6.3.4.8 repeatedly, we obtain an equivalence of $\infty$-categories

$$\Exc_* e^n, \mathcal{D}) \to \prod_{(s_1, \ldots, s_n) \in S^n} \Exc_*( \prod_{1 \leq i \leq n} e_{s_i}, \mathcal{D}).$$

The desired result is now obtained by extracting homotopy fixed points with respect to the action of the symmetric group $\Sigma_n$ on each side. \(\square\)

Remark 6.3.4.13. Let $\mathcal{C} = \prod_{s \in S} C_s$ and $\mathcal{D}$ be as in Lemma 6.3.4.12, and assume that $\mathcal{D}$ is pointed. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor. For every $\vec{n} = \{n_s\}_{s \in S}$ with $\sum_{s \in S} n_s = n$, we let $cr_{(\vec{n})}(F) \in \SymFun^{\vec{n}}(\mathcal{C}, \mathcal{D})$ be the composition of $cr_{(n_s)}(F) \in \SymFun^{(n_s)}(\mathcal{C}, \mathcal{D})$ with the functor $U_{\vec{n}} : e^{(n_s)} \to e^{(n)}$ in the statement of Lemma 6.3.4.12. Note that the underlying $n$-ary functor of $cr_{(\vec{n})}(F)$ is given by the functor $cr_{\vec{n}}(F) : \prod_{s \in S} e^{n_s} : \mathcal{C} \to \mathcal{D}$ appearing in Variant 6.1.3.21.

Proof of Proposition 6.3.4.11. Suppose we are given two sequences $\vec{m}$ and $\vec{n}$ with $|\vec{m}| = |\vec{n}| = n$. Consider the composite functor

$$U_{\vec{m}, \vec{n}} : \Homog^{\vec{m}}(\prod_{s \in S} C_s, \mathcal{D}) \subseteq \Homog^n(\mathcal{C}, \mathcal{D}) \overset{cr_{(n)}}{\to} \SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D}) \to \SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D}).$$

If $\vec{m} = \vec{n}$, then iterated application of Theorem 6.1.4.7 shows that $U_{\vec{m}, \vec{n}}$ is an equivalence of $\infty$-categories. If $\vec{m} \neq \vec{n}$, we claim that $U_{\vec{m}, \vec{n}}$ carries each object $F \in \Homog^{\vec{m}}(\prod_{s \in S} C_s, \mathcal{D})$ to a zero object of the $\infty$-category $\SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D})$. Using Remark 6.3.4.13, we are reduced to proving that $cr_{\vec{m}}(F)$ carries each object of $\prod_{s \in S} e^{m_s}$ to a zero object of $\mathcal{D}$. Since $\sum_{s \in S} m_s = \sum_{s \in S} n_s$, we have $m_s > n_s$ for some $s \in S$, in which case the desired result follows by applying Proposition 6.1.3.22 to the functor $C_s \to \Fun(\prod_{t \neq s} C_t, \mathcal{D})$ determined by $F$.

It follows from the above argument that the composite functor

$$\prod_{|\vec{m}| = n} \Homog^{\vec{m}}(\prod_{s \in S} C_s, \mathcal{D}) \overset{\Phi}{\to} \Homog^n(\mathcal{C}, \mathcal{D}) \overset{cr_{(n)}}{\to} \SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D}) \overset{\Psi}{\to} \prod_{|\vec{n}| = n} \SymFun^{\vec{n}}_{\text{lin}}(\mathcal{C}, \mathcal{D})$$

is an equivalence of $\infty$-categories, where $\Psi$ is the equivalence of $\infty$-categories appearing in Lemma 6.3.4.12. Since $cr_{(n)}$ is an equivalence of $\infty$-categories by Theorem 6.1.4.7, we conclude that $\Phi$ is an equivalence of $\infty$-categories. \(\square\)
We now turn to the proof of Theorem 6.3.3.14.

**Remark 6.3.4.14.** Let \( \{ C_s \} \) be a finite collection of pointed \( \infty \)-categories which admit finite colimits. Suppose we are given functors \( F, F' : \prod_{s \in S} C_s \to S_* \) and an element \( s \in S \) such that \( F' \) is 2-reduced when regarded as a functor from \( C_s \) to \( \text{Fun}(\prod_{t \neq s} C_t, S_*) \). Form fiber sequences

\[
H \to F \to \lim_{E \in \text{Equiv}^+(S)} F^E.
\]

\[
H' \to F' \to \lim_{E \in \text{Equiv}^+(S)} F'^E.
\]

Using Remark 6.1.1.29, we deduce that \( H' \) and each of the functors \( F'^{nE} \) is also 2-reduced when regarded as a functor \( C_s \to \text{Fun}(\prod_{t \neq s} C_t, S_*) \). It follows that the projection maps

\[
H \times H' \to H \quad (F \times F')^E \simeq F^E \times F'^E \to F^E
\]

induce equivalences after applying the functor \( P_t \) for \( t = (1, \ldots, 1) \), and therefore equivalences of differentials. Consequently, the conclusion of Theorem 6.3.3.14 is valid for \( F \) if and only if it is valid for the product \( F \times F' \).

**Proof of Theorem 6.3.3.14.** Let \( n \) be the cardinality of the set \( S \), let \( C = \prod_{s \in S} C_s \), and let \( \text{Exc}_\ast(\prod_{s \in S} C_s, S_*) \) denote the fullsubcategory of \( \text{Fun}(C, S_*) \) spanned by those functors which are reduced and excisive in each variable. Note that any functor \( F : \prod_{s \in S} C_s \to D \) which is 1-homogeneous in each variable is \( n \)-homogeneous when regarded as a functor from \( C \) to \( D \) (Corollary 6.1.3.11). It follows that any natural transformation \( F' \to F \) which induces an equivalence \( P_n F' \to P_n F \) also induces an equivalence of differentials \( D F' \to DF \).

Let \( F : \prod_{s \in S} C_s \to S_* \) be a functor which preserves final objects. For every subset \( T \subseteq S \), let \( F^T : C \to S_* \) be defined as in Construction 6.1.3.15, and note that \( (P_n F^T) \simeq P_n(F^T) \). Since \( P_n \) is left exact, we conclude that \( P_n \text{Red}(F) \simeq \text{Red}(P_n F) \). In particular, we have \( D \text{Red}(F) \simeq D \text{Red}(P_n F) \) and \( DF^E \simeq DP_n(F^E) \) for each equivalence relation \( E \) on \( S \). We may therefore replace \( F \) by \( P_n F \) and thereby reduce to the case where \( F \) is \( n \)-excisive.

Using Proposition 6.3.4.4, we can choose a jet equivalence \( F_n \to F \) such that each \( F_k \) is a finite product of homogeneous functors from \( C \) to \( D \). Let \( F' \) denote the functor \( |F_n| \). Note that for every subset \( T \subseteq S \), the functor \( F'^T \) is given by \( |F^T_n| \) (using the notation of Construction 6.1.3.15). Since geometric realizations in \( S \) commute with products, we deduce that for every equivalence relation \( E \) on \( S \), the canonical map \( |F^E_n| \to F^E \) is an equivalence. Since \( F' \to F \) is a jet equivalence, the left exactness of the functors \( P_m \) implies that \( F'^{nE} \to F^E \) is a jet equivalence for every \( E \in \text{Equiv}(S) \), so that we have a jet equivalence \( |F^E_n| \to F^E \). In particular, we obtain an equivalence of differentials \( D|F^E_n| \simeq DF^E \), so that \( DF^E \) is the geometric realization of the simplicial object \( DF^E_n \) in the \( \infty \)-category \( \text{Exc}_\ast(\prod_{s \in S} C_s, S_*) \). Since the \( \infty \)-category \( \text{Exc}_\ast(\prod_{s \in S} C_s, S_*) \) is stable (see Corollary 6.1.2.8), we deduce that the canonical map

\[
|\text{tfib}(DF^E_n)| \to \text{tfib}(|DF^E_n|) \quad \text{for } E \in \text{Equiv}(S)
\]

is an equivalence in \( \text{Exc}_\ast(\prod_{s \in S} C_s, S_*) \).

Let \( H_n \) be the simplicial functor given by \( \text{tfib}(DF^E_n) \), and let \( H = \text{tfib}(DF^E) \). It follows from Lemma 6.3.4.6 that the canonical map \( |H_n| \to H \) is a jet equivalence, so that \( DH \simeq D|H_n| \) is the geometric realization of the simplicial object of the simplicial object \( dH_n \) in the \( \infty \)-category \( \text{Exc}_\ast(\prod_{s \in S} C_s, S_*) \). It follows that the map

\[
DH \to \text{tfib}(DF^E_n) \quad \text{for } E \in \text{Equiv}(S)
\]

can be realized as a colimit of maps \( DH_m \to \text{tfib}(DF^E_m) \). We may therefore replace \( F \) by \( F_m \) and thereby reduce to the case where \( F \) is a finite product of reduced homogeneous functors.

Using Proposition 6.3.4.11, we can write \( F \) as a finite product \( \prod_{\alpha \in A} F_\alpha \), where each \( F(\alpha) \) belongs to \( \text{Hom}^\sim_n(\prod_{s \in S} C_s, S_*) \), where \( n_\alpha = \{ n_{\alpha,s} \}_{s \in S} \) is a collection of nonnegative integers with \( |n_\alpha| = \sum_{s \in S} n_{\alpha,s} > 0 \). Let \( A_0 \subseteq A \) be the subset consisting of those indices \( \alpha \) such that \( n_{\alpha,s} \leq 1 \) for all \( s \in S \). Let
\( \mathcal{F} = \prod_{\alpha \in A_0} F(\alpha) \). Applying Remark 6.3.4.14 repeatedly, we can replace \( F \) by \( \mathcal{F} \) and thereby reduce to the case where \( A_0 = A \). For every subset \( T \subseteq S \), let \( F_T \) denote the product of those functors \( F_\alpha \) for which \( \alpha \in A \) satisfies \( n_\alpha = \begin{cases} 1 & \text{if } s \in T \\ 0 & \text{if } s \notin T. \end{cases} \) Then \( F \simeq \prod_{\emptyset \neq T \subseteq S} F_T \), where each \( F_T \) can be written as a composition

\[
\prod_{s \in S} \mathcal{C}_s \to \prod_{s \in T} \mathcal{C}_s \xrightarrow{\mathcal{F}_T} \mathcal{S}_s
\]

for some functor \( \mathcal{F}_T \), which is reduced and excisive in each variable.

Let \( \mathcal{U} \) be a collection of nonempty subsets of \( S \), and set \( F_{\mathcal{U}} = \prod_{T \in \mathcal{U}} F_T \). Note that for \( E \in \text{Equiv}(S) \), we have \( F_E^\mathcal{U} = \prod_T F_T \), where the product is taken over all subsets \( T \in \mathcal{U} \) which are contained in a single equivalence class of the equivalence relation \( E \). If \( T \neq S \), then the collection of equivalence relations \( E \in \text{Equiv}^+(S) \) satisfying this condition has a smallest element, and therefore a weakly contractible nerve. It follows that \( \lim_{\leftarrow E \in \text{Equiv}^+(S)} F_E^\mathcal{U} \) is given by the product \( \prod_{T \in \mathcal{U}, T \neq S} F_T \). Form a fiber sequence

\[
H_{\mathcal{U}} \to F_{\mathcal{U}} \to \lim_{\leftarrow \mathcal{E} \in \text{Equiv}^+(S)} F_E^\mathcal{U},
\]

so that \( H_{\mathcal{U}} \simeq \begin{cases} F_S & \text{if } S \in \mathcal{U} \\ * & \text{otherwise,} \end{cases} \) where * denotes the constant functor \( \mathcal{C} \to \mathcal{S}_s \) carrying every object to a single point.

We will prove that for every collection \( \mathcal{U} \) of nonempty subsets of \( S \), the canonical map

\[
\theta_{\mathcal{U}} : DH_{\mathcal{U}} \to \text{tfib}\{DF_E^\mathcal{U}\}_{E \in \text{Equiv}(S)}
\]

is an equivalence. Taking \( \mathcal{U} = \mathbb{P}(S) \), we obtain a proof of the desired result. Our proof will proceed by induction on the cardinality of \( \mathcal{U} \). Let us therefore assume that \( \theta_{\mathcal{U}} \) is an equivalence for every proper subset \( \mathcal{U}' \subseteq \mathcal{U} \). Since the \( \infty \)-category \( \text{Exc}_*(\prod_{s \in S} \mathcal{C}_s, \mathcal{S}_s) \) is stable (Corollary 6.1.2.8) and the differentiation functor \( d : \text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{S}_s) \to \text{Exc}_*(\prod_{s \in S} \mathcal{C}_s, \mathcal{S}_s) \) preserves colimits, we deduce that the map

\[
\theta' : D(\lim_{\mathcal{U}' \subset \mathcal{U}} H_{\mathcal{U}'}) \to \text{tfib}\{D(\lim_{\mathcal{U}' \subset \mathcal{U}} F_E^\mathcal{U}')\}_{E \in \text{Equiv}(S)}
\]

For each equivalence relation \( E \in \text{Equiv}(S) \), let \( G(E) \) denote the cofiber of the canonical map

\[
\lim_{\mathcal{U}' \subset \mathcal{U}} F_E^\mathcal{U}' \to F_E^\mathcal{U}.
\]

When \( E = E_\perp \) is the discrete equivalence relation on \( S \) (that is, \( sE_\perp t \) for all \( s, t \in S \)), we denote \( G(E) \) by \( G \). Let \( H_0 \) denote the cofiber of the map \( \lim_{\mathcal{U}' \subset \mathcal{U}} H_{\mathcal{U}'} \to H_{\mathcal{U}} \). Using the description of the functor \( H_{\mathcal{U}} \) given above, we see that

\[
H_0 = \begin{cases} F_S & \text{if } \mathcal{U} = \{S\} \\ 0 & \text{otherwise.} \end{cases}
\]

We have a fiber sequence

\[
\theta' \to \theta_{\mathcal{U}} \to \theta''
\]

in the stable \( \infty \)-category \( \text{Fun}(\Delta^1, \text{Exc}_*(\prod_{s \in S} \mathcal{C}_s, \mathcal{S}_s)) \), where \( \theta'' \) denotes the canonical map

\[
dH_0 \to \text{tfib}\{DG(E)\}_{E \in \text{Equiv}(S)}.
\]

Consequently, to prove that \( \theta_{\mathcal{U}} \) is an equivalence, it will suffice to show that \( \theta'' \) is an equivalence. If \( \mathcal{U} = \{S\} \), then \( H_0 \simeq G \simeq F_S \) and \( G \) is trivial for \( E \in \text{Equiv}^+(S) \). Let us therefore assume that \( \mathcal{U} \neq \{S\} \). Then \( H_0 \) is trivial, so we are reduced to proving that the canonical map

\[
\phi : DG \to \text{tfib}\{DG(E)\}_{E \in \text{Equiv}(S)}
\]
is an equivalence.

Let \( \wedge : S_s \times S_s \to S_s \) denote the smash product functor on pointed spaces (see Example 6.2.3.28). Unwinding the definitions, we see that for each equivalence relation \( E \in \text{Equiv}(S) \), the functor \( G(E) \) is given by the smash product \( \wedge_{T \in \mathcal{U}} F_T \) if each element \( T \in \mathcal{U} \) is contained in an equivalence class of \( E \), and is trivial otherwise. There are several cases to consider:

(a) Suppose there is some element \( s \in S \) which does not belong to any element of \( \mathcal{U} \). Then each of the functors \( G(E) \) is constant when regarded as a functor \( \mathcal{C}_s \to \text{Fun}(\prod_{i \neq s} \mathcal{C}_i, S_s) \), so that the differential \( DG(E) \) is a zero object of \( \text{Exc}_s(\prod_{s \in S} \mathcal{C}_s, S_s) \). In this case, \( \phi \) is a map between zero objects of \( \text{Exc}_s(\prod_{s \in S} \mathcal{C}_s, S_s) \), and therefore an equivalence.

(b) Suppose that some element \( s \in S \) belongs to \( T \cap T' \) for some pair of distinct elements \( T, T' \in \mathcal{U} \). Using Proposition 6.1.3.10, we deduce that each of the functors \( G(E) \) is 2-reduced when regarded as a functor from \( \mathcal{C}_s \) to \( \text{Fun}(\prod_{i \neq s} \mathcal{C}_i, S_s) \), so that the differential \( DG(E) \) vanishes (Remark 6.3.4.14). We again see that \( \phi \) is a map between zero objects of \( \text{Exc}_s(\prod_{s \in S} \mathcal{C}_s, S_s) \), and therefore an equivalence.

(c) Suppose that \( \mathcal{U} = \{T_1, \ldots, T_k\} \) for some collection of disjoint nonempty subsets \( T_1, \ldots, T_k \subseteq S \) satisfying \( S = \bigcup T_i \). Let \( \text{Equiv}^{++}(S) \subseteq \text{Equiv}^+(S) \) be the subset consisting of those equivalence relations such that each \( T_i \) is contained in an equivalence class. Our analysis above shows that the functors \( G(E) \) are given by the formula

\[
G(E) = \begin{cases} 
G & \text{if } E \in \text{Equiv}^{++}(S) \\
* & \text{otherwise},
\end{cases}
\]

so that the diagram \( (E \in \text{Equiv}^+(S)) \to G(E) \) is a right Kan extension of its restriction to the \( \infty \)-category \( N(\text{Equiv}^{++}(S))\text{op} \). Consequently, to prove that \( \phi \) is an equivalence, it will suffice to show that the simplicial set \( N(\text{Equiv}^{++}(S)) \) is weakly contractible. In fact, the partially ordered set \( \text{Equiv}^{++}(S) \) has a smallest element: namely, the equivalence relation whose equivalence classes are precisely the sets \( T_i \) (note that this equivalence relation belongs to \( \text{Equiv}^+(S) \) by virtue of our assumption that \( \mathcal{U} \neq \{S\} \)).

\( \square \)

### 6.3.5 Consequences of Theorem 6.3.3.14

Let \( \{\mathcal{C}_s\}_{s \in S} \) be a nonempty finite collection of pointed \( \infty \)-categories which admit finite colimits, let \( \mathcal{D} \) be a pointed differentiable \( \infty \)-category, and let

\[
D : \text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \to \text{Exc}_s(\prod_{s \in S} \mathcal{C}_s, \mathcal{D})
\]

be a left adjoint to the inclusion (given by differentiation). When restricted to the full subcategory of \( \text{Fun}(\prod_{s \in S} \mathcal{C}_s, \mathcal{D}) \) spanned by those functors which are reduced in each variable, the functor \( D \) coincides with \( P_\mathcal{I} \) of Proposition 6.1.3.6 (with \( \mathcal{I} = \{1, 1, \ldots, 1\} \)), and is therefore left exact. In general \( D \) is not left exact. Nevertheless, Theorem 6.3.3.14 implies that \( D \) commutes with a very special type of limits. In this section, we will apply Theorem 6.3.3.14 to show that differentiation commutes with a larger class of limits (Theorem 6.3.5.5). We will also obtain a generalization of the chain rule of Theorem 6.2.1.22 to the case of nonreduced functors (Theorem 6.3.5.6).

We begin by formulating a more general version of Theorem 6.3.3.14.

**Notation 6.3.5.1.** Let \( p : S \to T \) be a map of finite sets. For each \( t \in T \), we let \( S_t \) denote the fiber of \( p^{-1}\{t\} \subseteq S \). We let \( \text{Equiv}_p(S) \) denote the subset of \( \text{Equiv}(S) \) consisting of those equivalence relations \( E \) on \( S \) such that \( p \) is constant on each equivalence class: that is, equivalence relations for which \( xEy \) implies...
6.3. THE CHAIN RULE

Let \( p : S \to T \) be a surjective map of nonempty finite sets. Suppose we are given a collection of pointed \( \infty \)-categories \( \{ C_s \}_{s \in S} \) which admit finite colimits, a collection of pointed \( \infty \)-categories \( \{ D_t \}_{t \in T} \), and a pointed presentable differentiable \( \infty \)-category \( \mathcal{E} \). Let \( \{ F_t : \prod_{p(s) = t} C_s \to D_t \} \) and \( G : \prod_{t \in T} D_t \to \mathcal{E} \) be functors which preserve zero objects. For each \( E \in \text{Equiv}_p(S) \), let \( F^E \) denote the functor

\[
\prod_{s \in S} C_s \xrightarrow{F^E} \prod_{t \in T} D_t.
\]

Then the canonical map

\[
D(G \circ \text{tfib}\{ F^E \}|_{E \in \text{Equiv}_p(S)}) \to \text{tfib}\{ D(G \circ F^E) \}|_{E \in \text{Equiv}_p(S)}
\]

is an equivalence in the \( \infty \)-category \( \text{Exc}_s(\prod_{s \in S} C_s, \mathcal{E}) \).

Remark 6.3.5.3. In the special case where \( T \) has a single element, \( \mathcal{E} = S_* \), and the functor \( G \) is an equivalence, Proposition 6.3.5.2 reduces to Theorem 6.3.3.14.

Before giving the proof of Proposition 6.3.5.2, let us describe some of its consequences.

Notation 6.3.5.4. If \( \mathcal{C} \) and \( \mathcal{D} \) are compactly generated \( \infty \)-categories, we let \( \text{Fun}^c(\mathcal{C}, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) spanned by those functors which preserve filtered colimits.

Theorem 6.3.5.5. Let \( S \) be a nonempty finite set. Suppose we are given compactly generated pointed \( \infty \)-categories \( \{ C_s \}_{s \in S} \), and \( \mathcal{D} \). Let \( K \) be a finite simplicial set and suppose we are given a diagram

\[
\alpha : K^\triangledown \to \text{Fun}^c(\prod_{s \in S} C_s, \mathcal{D}),
\]

carrying each vertex \( v \in K^\triangledown \) to a functor \( F_v : \prod_{s \in S} C_s \to \mathcal{D} \). For every nonempty subset \( S' \subseteq S \), let \( F_{v, S'} \) denote the restriction of \( F_v \) to

\[
\prod_{s \in S'} C_s \cong \prod_{s \in S'} C_s \times \prod_{s \in S - S'} \{ *_s \} \subseteq \prod_{s \in S} C_s;
\]

here \( *_s \) denotes a zero object of \( C_s \) for \( s \in S \). Assume that:

1. Each of the functors \( F_v \) carries zero objects of \( \prod_{s \in S} C_s \) to zero objects of \( \mathcal{D} \).

2. For each equivalence relation \( E \in \text{Equiv}(S) \), there exists a map of finite simplicial sets \( u : K \to \prod_{S' \in S/E} K_{S'} \) satisfying the following conditions:

   (a) The map of simplicial sets \( u \) is right cofinal.

   (b) For each \( S' \in S/E \), there exists a limit diagram \( \beta_{S'} : K^\triangledown_{S'} \to \text{Fun}^c(\prod_{s \in S'} C_s, \mathcal{D}) \) such that the composite map

\[
K^\triangledown \xrightarrow{u} \prod_{S'' \in S/E} K^\triangledown_{S''} \xrightarrow{\beta_{S'}} \text{Fun}^c(\prod_{s \in S'} C_s, \mathcal{D})
\]

is given by \( v \mapsto F_{v, S'} \).
Let \( v_0 \) denote the cone point of \( K^\circ \). Then the canonical map
\[
\phi : \tilde{\partial}(F_{v_0}) \to \lim_{v \in K} \tilde{\partial}(F_v)
\]
is an equivalence in \( \text{Exc}_v(\prod_{s \in S} \text{Sp}(E_s), \text{Sp}(\mathcal{D})) \).

Proof of Theorem 6.3.5.5. For every compact object \( D \in \mathcal{D} \), let \( J_D : \mathcal{D} \to \mathcal{S}_* \) denote the functor corepresented by \( D \). Then \( J_D \) is left exact, so that its derivative \( j_D = \partial(J_D) : \text{Sp}(\mathcal{D}) \to \text{Sp} \) is given by pointwise composition with \( J_D \) (Example 6.2.1.4). Since \( \mathcal{D} \) is compactly generated, the functors \( j_D \) are jointly conservative. Consequently, it will suffice to show that each of the induced maps
\[
\alpha_G : j_D \circ \tilde{\partial}(F_{v_0}) \to \lim_{v \in K} j_D \circ \tilde{\partial}(F_v)
\]
is an equivalence. Using Theorem 6.2.1.22, we can identify \( \tilde{\partial}(F_{v_0}) \) with the map
\[
\tilde{\partial}(J_D \circ \prod_{s \in S} F_s) \to \lim_{v \in K} \tilde{\partial}(J_D \circ F_v).
\]
We may therefore replace \( F \) by \( J_D \circ F \) and thereby reduce to the case where \( \mathcal{D} = \mathcal{S}_* \).

For each equivalence relation \( E \in \text{Equiv}(\mathcal{S}) \), let \( \phi_E \) denote the canonical map \( \tilde{\partial}(F_{v_0}) \to \lim_{v \in K} \tilde{\partial}(F_v) \). We will prove that each of the maps \( \phi_E \) is an equivalence. The proof will proceed by induction. For every equivalence relation \( E \), let \( \text{Equiv}_E(\mathcal{S}) \) denote the collection of equivalence relations on \( \mathcal{S} \) that refine \( E \) (that is, \( \text{Equiv}_E(\mathcal{S}) = \{ E' \in \text{Equiv}(\mathcal{S}) : E' \leq E \} \)) and let \( \text{Equiv}_E^+(\mathcal{S}) = \text{Equiv}_E(\mathcal{S}) - \{ E \} \). To complete the proof, it will suffice to show that if \( E \in \text{Equiv}(\mathcal{S}) \) has the property that \( \phi_{E'} \) is an equivalence for each \( E' \in \text{Equiv}_E^+(\mathcal{S}) \), then \( \phi_E \) is an equivalence.

Fix an equivalence relation \( E \in \text{Equiv}(\mathcal{S}) \) as above, and let \( T = S/E \). Let \( G : \prod_{t \in T} \mathcal{S}_* \to \mathcal{S}_* \) denote the functor given by iterated Cartesian product. Then \( \phi_E \) can be identified with the upper horizontal map appearing in the diagram \( \sigma : \)
\[
\begin{align*}
\tilde{\partial}(G \circ \prod_{s' \in \mathcal{S}} F_{v_0,s'}) & \to \lim_{v \in K} \tilde{\partial}(G \circ \prod_{s' \in \mathcal{S}} F_{v,s'}) \\
\lim_{t \in T} \text{Diff}(G \circ \prod_{s' \in \mathcal{S}} F_{v_0,s'}) & \to \lim_{t \in T} \lim_{v \in K} \text{Diff}(G \circ \prod_{s' \in \mathcal{S}} F_{v,s'}).
\end{align*}
\]
Here the lower horizontal map is an equivalence by the inductive hypothesis. Since \( \text{Exc}_v(\prod_{s \in S} \text{Sp}(E_s), \text{Sp}) \) is a stable \( \infty \)-category, it will suffice to show that \( \sigma \) induces an equivalence after passing to the fibers of the vertical maps. Using Proposition 6.3.5.2, we are reduced to providing that the map
\[
\tilde{\partial}(G \circ \prod_{s' \in T} \text{Red}(F_{v_0,s'})) \to \lim_{v \in K} \tilde{\partial}(G \circ \prod_{s' \in T} \text{Red}(F_{v,s'}))
\]
is an equivalence.

Let \( G' : \prod_{t \in T} \mathcal{S}_* \to \mathcal{S}_* \) denote the iterated smash product functor. For each vertex \( v \in K \), the canonical map
\[
G \circ \prod_{s' \in T} \text{Red}(F_{v,s'}) \to G' \circ \prod_{s' \in T} \text{Red}(F_{v,s'}),
\]
induces an equivalence of derivatives. It will therefore suffice to show that the canonical map
\[
\theta : \tilde{\partial}(G' \circ \prod_{s' \in T} \text{Red}(F_{v_0,s'})) \to \lim_{v \in K} \tilde{\partial}(G' \circ \prod_{s' \in T} \text{Red}(F_{v,s'}))
\]
is an equivalence. Using Theorem 6.2.1.22 and Example 6.2.3.28, we can identify \( \theta \) with the canonical map

\[
\theta' : \otimes_{v' \in T} \tilde{\partial}(\text{Red}(F_{v_0, v'})) \to \varprojlim_{v \in K} \otimes_{v' \in T} \tilde{\partial}(\text{Red}(F_{v, v'})).
\]

Choose a map \( u : K \to \prod_{v' \in S/E} K_{v'} \) and maps \( \beta_{v'} : K_{v'} \to \text{Fun}(\prod_{v' \in E} \mathcal{C}_s, \mathcal{D}) \) as in (2). For \( S' \in T \), let \( v_0, v' \) denote the cone point of \( K_{v'} \). Using the right cofinality of \( u \), we can identify \( \theta \) with the canonical map

\[
\otimes_{v' \in T} \tilde{\partial}\text{Red}(\beta_{v'}(v_0, v')) \to \varprojlim_{v' \in K_{v'}} \otimes_{v' \in T} \tilde{\partial}\text{Red}(\beta_{v'}(v')) \simeq \otimes_{v' \in K_{v'}} \lim_{v' \in K_{v'}} \tilde{\partial}\text{Red}(\beta_{v'}(v')).
\]

We are therefore reduced to proving that for each \( S' \in T \), the canonical map

\[
\tilde{\partial}\text{Red}(\beta_{v'}(v_0, v')) \to \varprojlim_{v' \in K_{v'}} \tilde{\partial}\text{Red}(\beta_{v'}(v'))
\]

is an equivalence. Since differentiation is left exact when restricted to functors which are reduced in each variable, so it suffices to show that \( \text{Red}(\beta_{v'}(v_0, v')) \simeq \varprojlim_{v' \in K_{v'}} \text{Red}(\beta_{v'}(v')) \) is an equivalence. This follows from our assumption that \( \beta_{v'} \) is a limit diagram, since the reduction functor \( \text{Red} \) is left exact.

**Theorem 6.3.5.6.** Let \( p : S \to T \) be a surjective map of nonempty finite sets. Suppose we are given compactly generated pointed \( \infty \)-categories \( \{ \mathcal{C}_s \}_{s \in S}, \{ \mathcal{D}_t \}_{t \in T}, \) and \( \mathcal{E} \). Let \( G \in \text{Fun}^c(\prod_{t \in T} \mathcal{D}_t, \mathcal{E}) \). Let \( K \) be a finite simplicial set, and suppose that for each \( t \in T \) we are given a diagram

\[
K^a \to \text{Fun}^c(\prod_{s \in S_t} \mathcal{C}_s, \mathcal{D}_t),
\]

carrying each vertex \( v \in K^a \) to a functor \( F_{t,v} : \prod_{s \in S_t} \mathcal{C}_s \to \mathcal{D}_t \). Assume that:

1. Each of the functors \( F_{t,v} \) carries zero objects of \( \prod_{s \in S_t} \mathcal{C}_s \) to zero objects of \( \mathcal{D}_t \), and \( G \) carries zero objects of \( \prod_{t \in T} \mathcal{D}_t \) to zero objects of \( \mathcal{E} \).

2. For each \( E \in \text{Equiv}_p^+(S) \), there exists a map of finite simplicial sets \( u : K^a \to K^a_E \) satisfying the following conditions:

   a. The underlying map \( K \to K^a_E \) is right cofinal.
   b. For each \( t \in T \), the functor \( K^a \to \text{Fun}^c(\prod_{s \in S_t} \mathcal{C}_s, \mathcal{D}_t) \) given by \( v \mapsto F_{t,v}^E \) factors through \( u \).
   c. The map \( u \) carries the cone point of \( K^a \) to the cone point of \( K^a_E \).

Let \( v_0 \) denote the cone point of \( K^a \). Then the diagram \( \sigma \):

\[
\begin{array}{ccc}
\tilde{\partial}(G \circ \prod_{t \in T} F_{t,v_0}) & \longrightarrow & \varprojlim_{v \in K} \tilde{\partial}(G \circ \prod_{t \in T} F_{t,v}) \\
\downarrow & & \downarrow \\
\tilde{\partial}(G) \circ \prod_{t \in T} \tilde{\partial}(F_{t,v_0}) & \longrightarrow & \varprojlim_{v \in K} \tilde{\partial}(G) \circ \prod_{t \in T} \tilde{\partial}(F_{t,v})
\end{array}
\]

is a pullback square in \( \text{Fun}(\prod_{s \in S} \text{Sp}(\mathcal{C}_s), \text{Sp}(\mathcal{E})) \).

**Proof.** For each \( E \in \text{Equiv}_p^+(S) \), let \( \sigma(E) \) denote the diagram

\[
\begin{array}{ccc}
\tilde{\partial}(G \circ \prod_{t \in T} F_{t,v_0}^E) & \longrightarrow & \varprojlim_{v \in K} \tilde{\partial}(G \circ \prod_{t \in T} F_{t,v}^E) \\
\downarrow & & \downarrow \\
\tilde{\partial}(G) \circ \prod_{t \in T} \tilde{\partial}(F_{t,v_0}^E) & \longrightarrow & \varprojlim_{v \in K} \tilde{\partial}(G) \circ \prod_{t \in T} \tilde{\partial}(F_{t,v}^E).
\end{array}
\]
Form a fiber sequence
\[ \tau \to \sigma \to \lim_{E \in \text{Equiv}^+(S)} \sigma(E). \]

in the stable \( \infty \)-category \( \text{Fun}(\Delta^1 \times \Delta^1, \text{Ex}_* (\prod_{s \in S} \text{Sp}(c_s), \text{Sp}(E))) \). To prove that \( \sigma \) is a pullback diagram, it will suffice to show that \( \tau \) is a pullback diagram and that \( \sigma(E) \) is a pullback diagram, for each \( E \in \text{Equiv}^+(S) \).

We first show that \( \tau \) is a pullback diagram. Unwinding the definitions, we can write \( \tau \) as a commutative diagram
\[
\begin{array}{c}
\text{tfib}\{\partial(G \circ \prod_{t} F_{t,v})\}_{E \in \text{Equiv}(S)} \\
\downarrow \\
\text{tfib}\{\partial(G) \circ \prod_{t} (F_{t,v}^E)\}_{E \in \text{Equiv}(S)}
\end{array}
\]

To prove that this diagram is a pullback square, it will suffice to show that the vertical maps are equivalences. Fix a vertex \( v \in K^d \); we will show that the map
\[
\theta : \text{tfib}\{\partial(G \circ \prod_{t} F_{t,v})\}_{E \in \text{Equiv}(S)} \to \text{tfib}\{\partial(G) \circ \prod_{t} (F_{t,v}^E)\}_{E \in \text{Equiv}(S)}
\]
is an equivalence. Since the functor \( \partial(G) \) is left exact in each variable, the right hand side is given by
\[
\partial(G) \circ \prod_{t} \text{tfib}\{\partial(F_{t,v}^E)\}_{E \in \text{Equiv}(S_i)}.
\]

We have a commutative diagram
\[
\begin{array}{c}
\text{tfib}\{\partial(G) \circ \prod_{t} F_{t,v}^E\}_{E \in \text{Equiv}(S)} \\
\downarrow \theta' \\
\text{tfib}\{\partial(G) \circ \prod_{t} (F_{t,v}^E)\}_{E \in \text{Equiv}(S)} \\
\downarrow \theta \\
\partial(G) \circ \prod_{t} \text{tfib}\{\partial(F_{t,v}^E)\}_{E \in \text{Equiv}(S_i)}
\end{array}
\]
The horizontal maps in this diagram are equivalences by Proposition 6.3.5.2. We are therefore reduced to proving that \( \theta' \) is an equivalence. This follows from Theorem 6.2.1.22, since each of the functors \( \text{tfib}\{F_{t,v}^E\} \) is reduced in each variable. This completes the proof that \( \tau \) is a pullback square.

Now suppose that \( E \in \text{Equiv}^+(S) \); we will show that the diagram \( \sigma(E) \) is a pullback square. Choose a map \( u : K^d \to K_E^d \) satisfying the requirements of hypothesis (2). Condition (b) implies that for each \( t \in T \), we can choose a diagram \( u' : K^d \to \text{Fun}^c(\prod_{s \in S_i} c_s, U_t) \) such that the composition of \( u' \circ u_t \) is given by the formula \( v \mapsto F_{t,v}^E \). Let \( K_E^d \) denote the product \( \prod_{t} T_{t,E}^d \). For each vertex \( w \in \{w_t\}_{t \in T} \), let \( H_{t,w} : \prod_{s \in S_i} c_s \to U_t \) denote the image of \( w_t \) under the diagram \( u'_t \). Then we rewrite \( \sigma(E) \) as a diagram
\[
\begin{array}{c}
\text{tfib}\{\partial(G) \circ \prod_{t} H_{t,w_t}\}_{E \in \text{Equiv}(S)} \\
\downarrow \\
\text{tfib}\{\partial(G) \circ \prod_{t} H_{t,w}\}_{E \in \text{Equiv}(S)}
\end{array}
\]

Let \( w_0 \) denote the cone point of \( K_E^d \). Using assumptions (a) and (c), we can rewrite the diagram \( \sigma(E) \) again:
\[
\begin{array}{c}
\text{tfib}\{\partial(G) \circ \prod_{t} H_{t,w_0}\}_{E \in \text{Equiv}(S)} \\
\downarrow \\
\text{tfib}\{\partial(G) \circ \prod_{t} H_{t,w}\}_{E \in \text{Equiv}(S)}
\end{array}
\]
6.3. THE CHAIN RULE

Since $K^E_\infty$ contains $w_0$ as an initial object, the horizontal maps in this diagram are equivalences. □

The proof of Proposition 6.3.5.2 will require a bit of terminology.

**Notation 6.3.5.7.** Let $\{\mathcal{E}_s\}_{s \in S}$ be a nonempty finite collection of pointed $\infty$-categories which admit finite colimits, and let $D$ be a differentiable $\infty$-category. Suppose we are given functors

$$F : \prod_{s \in S} \mathcal{E}_s \to D \quad f : \prod_{s \in S} \mathcal{E}_s \to \text{Sp}(D).$$

We will say that a natural transformation $\alpha : F \to \Omega_\infty^D \circ f$ exhibits $f$ as a predifferential of $F$ if it exhibits $\Omega_\infty^D \circ f$ as a differential of $f$, in the sense of Definition 6.2.3.1.

Using Proposition 1.4.2.22, we see that $\Omega_\infty^D$ induces a trivial Kan fibration

$$\text{Exc}_s(\prod_{s \in S} \mathcal{E}_s, \text{Sp}(D)) \to \text{Exc}_s(\prod_{s \in S} \mathcal{E}_s, D).$$

It follows from Proposition 6.2.3.13 that for every functor $F : \prod_{s \in S} \mathcal{E}_s \to D$, there exists a functor $f : \prod_{s \in S} \mathcal{E}_s \to \text{Sp}(D)$ and a natural transformation $\alpha : F \to \Omega_\infty^D \circ f$. The functor $f$ is determined by $f$ up to equivalence; we will denote it by $d(F)$.

**Example 6.3.5.8.** In the situation of Notation 6.3.5.7, let $\Sigma_\infty^D : D \to \text{Sp}(D)$ be a left adjoint to $\Omega_\infty^D$ (Proposition 6.2.3.16). Then a natural transformation $\alpha : F \to \Omega_\infty^D \circ f$ exhibits $f$ as a predifferential of $F$ if and only if the adjoint map $\Sigma_\infty^D \circ F \to f$ exhibits $f$ as a differential of $\Sigma_\infty^D \circ F$.

**Lemma 6.3.5.9.** Let $p : S \to T$ be a surjective map between nonempty finite sets, and let $\{\mathcal{E}_s\}_{s \in S}$ be a collection of pointed $\infty$-categories which admit finite colimits. Suppose we are given a collection of functors $\{F_t : \prod_{p(s)=t} \mathcal{E}_s \to S_s\}_{t \in T}$ such that each $F_t(\{s\}_{p(s)=t})$ is contractible. Let $F$ denote the composite functor

$$\prod_{s \in S} \mathcal{E}_s \xrightarrow{\prod F_t} \prod_{t \in T} S_s \xrightarrow{\sim} S_s.$$

For each $E \in \text{Equiv}_p(S)$, let $F^E_\infty$ denote the composition

$$\prod_{s \in S} \mathcal{E}_s \xrightarrow{\prod F^E_t} \prod_{t \in T} S_s \xrightarrow{\sim} S_s.$$

Then the canonical map

$$d \text{tfib}(F^E_\infty)_{E \in \text{Equiv}_p(S)} \to \text{tfib}(dF^E_\infty)_{E \in \text{Equiv}_p(S)}$$

is an equivalence.

**Proof.** Let $E \in \text{Equiv}_p(S)$. Since the formation of products in $S$ preserves colimits separately in each variable, the product functor on $S_s$ preserves contractible colimits separately in each variable. It follows that the coreduction of $F^E_\infty$ is given by the composition

$$\prod_{s \in S} \mathcal{E}_s \xrightarrow{\prod_{t \in T} \text{cored}(F^E_t)} \prod_{t \in T} S_s \xrightarrow{\sim} S_s.$$

Consequently, the functor $\Sigma_\infty \circ \text{cored}(F^E_\infty) : \prod_{s \in S} \mathcal{E}_s \to \text{Sp}$ is given by the composition

$$\prod_{s \in S} \mathcal{E}_s \xrightarrow{\prod_{t \in T} \text{cored}(F^E_t)} \prod_{t \in T} S_s \xrightarrow{\Sigma_\infty} \prod_{t \in T} \text{Sp} \xrightarrow{\otimes} \text{Sp}.$$
where \(\otimes\) denotes the functor given by iterated smash product of spectra. Since the functor \(\otimes\) is left exact and preserves sequential colimits in each variable, we have canonical equivalences

\[
d(F^E_X) \simeq d(\text{cored}(F^E_X)) \\
\simeq D(\Sigma^\infty \circ \text{cored}(F^E_X)) \\
\simeq \otimes_{t \in T} D(\Sigma^\infty \circ \text{cored}(F^E_t)) \\
\simeq \otimes_{t \in T} d(\text{cored}(F^E_t)) \\
\simeq \otimes_{t \in T} d(F^E_t).
\]

It follows that the differential \(d(F^E_X)\) is given by the composition

\[
\prod_{s \in S} c_s d(F^E_t) \prod_{t \in T} \text{Sp} \overset{\otimes}{\rightarrow} \text{Sp} \overset{\Omega^\infty}{\rightarrow} S_*.
\]

Since the formation of smash products of spectra is left exact in each variable, Remark 6.3.3.9 implies that the total fiber \(\text{tfib}\{D(F^E_X)\}_{E \in \text{Equiv}_s(S)}\) is given by the composition

\[
\prod_{s \in S} c_s \text{tfib}(d(F^E_t)) \prod_{t \in T} \text{Sp} \overset{\otimes}{\rightarrow} \text{Sp} \overset{\Omega^\infty}{\rightarrow} S_*.
\]

Invoking Theorem 6.3.3.14, we can identify this composition with the functor

\[
\prod_{s \in S} c_s \prod_{t \in T} \text{Red}(F_t) \prod_{t \in T} \text{Sp} \overset{\otimes}{\rightarrow} \text{Sp} \overset{\Omega^\infty}{\rightarrow} S_*,
\]

which is the differential of the functo

\[
\prod_{s \in S} c_s \prod_{t \in T} \text{Red}(F_t) \prod_{t \in T} S_* \overset{\times}{\rightarrow} S_*.
\]

Using Remark 6.3.3.9 again, we can identify this composition with \(\text{tfib}\{F^E_X\}_{E \in \text{Equiv}_s(S)}\).

Proof of Proposition 6.3.5.2. It will suffice to show that the natural transformation

\[
d(G \circ \text{tfib}\{F^E\}_{E \in \text{Equiv}_s(S)}) \rightarrow \text{tfib}\{d(G \circ F^E)\}_{E \in \text{Equiv}_s(S)}
\]

is an equivalence in \(\text{Fun(}\prod_{s \in S} c_s, \text{Sp}(E))\) (we can then deduce the analogous result for differentials by composing with the left exact functor \(\Omega^\infty\)). Replacing \(G\) by \(\Sigma^\infty \circ G\) (and using Example 6.3.5.8), we are reduced to proving Proposition 6.3.3.14 in the special case where the \(\infty\)-category \(E\) is stable.

We may assume without loss of generality that the \(\infty\)-categories \(E_s\) and \(D_t\) are small. Let \(X\) denote the full subcategory of \(\text{Fun(}\prod_{s \in S} c_s, \text{Sp}(E))\) spanned by those functors which preserve zero objects. Let us regard the functors \(F_t : \prod_{p(s)=t} c_s \rightarrow D_t\) as fixed, and allow \(G\) to vary over objects of \(X\). For each \(G \in X\), let \(\theta_G\) denote the canonical map

\[
\text{D}(G \circ \text{tfib}\{F^E\}_{E \in \text{Equiv}_s(S)}) \rightarrow \text{tfib}\{\text{D}(G \circ F^E)\}_{E \in \text{Equiv}_s(S)}.
\]

Let \(X_0 \subseteq X\) denote the full subcategory spanned by those functors \(G \in X\) such that \(\theta_G\) is an equivalence. We wish to show that \(X_0 = X\).

For every collection of objects \(\bar{D} = \{D_t \in D_t\}_{t \in T}\) and every object \(E \in \mathcal{E}\), let \(G_{\bar{D},E} \in X\) be the functor given by the formula

\[
G_{\bar{D},E}(\{D'_t\}_{t \in T}) = (\prod_{t \in T} \text{Map}_{D_t}(D_t, D'_t)) \wedge E.
\]
Recall that Theorem 6.3.2.3 asserts that if

\[ q \]  

some mild hypotheses, then the stabilization of \( \mathcal{E} \) is generated by a small collection of objects under small colimits, and is therefore a presentable \( \infty \)-category.

Using Corollary T.5.5.2.9, we deduce that the inclusion \( \mathcal{X}_1 \to \mathcal{X} \) admits a right adjoint \( V \). We claim that \( V \) is conservative (so that \( \mathcal{X}_1 \subseteq \mathcal{X} \)). To prove this, consider a morphism \( \alpha : G \to G' \) in \( \mathcal{X} \) such that \( V(\alpha) \) is an equivalence. Then the composite map

\[
\text{Map}_\mathcal{E}(E, G(D)) \simeq \text{Map}_\mathcal{X}(G_{\tilde{D}, E}, G) \to \text{Map}_\mathcal{X}(G_{\tilde{D}, E}, G') \simeq \text{Map}_\mathcal{E}(E, G'(\tilde{D}))
\]

is a homotopy equivalence for every pair \((\tilde{D}, E)\), from which it follows that \(\alpha\) is an equivalence.

To prove that \( \mathcal{X}_0 = \mathcal{X} \), it will suffice to show that \( \mathcal{X}_1 \subseteq \mathcal{X}_0 \). Using the stability of \( \mathcal{E} \), we deduce that the construction \( G \mapsto \theta_G \) preserves small colimits. It follows that \( \mathcal{X}_0 \) is closed under small colimits in \( \mathcal{X} \). It will therefore suffice to show that \( G_{\tilde{D}, E} \in \mathcal{X}_1 \) for every pair \((\tilde{D}, E)\). In other words, we can reduce to the case where the functor \( G \) is given by a composition

\[
\prod_{t \in T} \mathcal{D}_t \xrightarrow{e_{\tilde{D}}} S_* \xrightarrow{\Sigma^n} \text{Sp}^E \times \mathcal{E}.
\]

where \( e_{\tilde{D}} \) denotes the functor corepresented by \( \tilde{D} \in \prod_{t \in T} \mathcal{D}_t \). Since the last of these functors commutes with small colimits and finite limits, we can replace \( G \) by the composition \( \Sigma^n \circ e_{\tilde{D}} \) and \( \mathcal{E} \) by the \( \infty \)-category of spectra. Using Example 6.3.5.8, we are reduced to proving that the canonical map

\[
\psi : d(e_{\tilde{D}} \circ \text{tfib}(F^E)_{E \in \text{Eqiv}_p(S)}) \to \text{tfib}(d(e_{\tilde{D}} \circ F^E))_{E \in \text{Eqiv}_p(S)}.
\]

For each \( t \in T \), let \( F_t' : \prod_{p(s)=t} C_S \to S_* \) denote the composite functor

\[
\prod_{p(s)=t} C_S \xrightarrow{e_{S}} \mathcal{D}_t \xrightarrow{\text{Map}_{\mathcal{D}}(D_t, \bullet)} S_*.
\]

Since corepresentable functors preserve limits, we can identify \( \psi \) with the canonical map

\[
D(\text{tfib}(F'^E)_{E \in \text{Eqiv}_p(S)}) \to \text{tfib}(d(F'^E))_{E \in \text{Eqiv}_p(S)}.
\]

The desired result now follows from Lemma 6.3.5.9. \( \square \)

### 6.3.6 The Dual Chain Rule

Recall that Theorem 6.3.2.3 asserts that if \( q : \mathcal{C} \to \Delta^2 \times N(\text{Fin}_*) \) is a thin \( \Delta^2 \)-family of \( \infty \)-operads satisfying some mild hypotheses, then the stabilization of \( q \) is also a thin \( \Delta^2 \)-family of \( \infty \)-operads. We will devote the entirety of this section to the proof of Theorem 6.3.2.3. We begin with a simple combinatorial lemma.

**Lemma 6.3.6.1.** Let \( K \) be a finite product of simplices \( \prod_{1 \leq i \leq n} \Delta^a_i \), and let \( v \) denote the final vertex of \( K \). Let \( P \) denote the partially ordered set of nondegenerate simplices of \( K \) (ordered by inclusion) and let \( P^0 = P - \{v\} \). If at least one of the integers \( a_i \) is positive, then \( N(P^0) \) is weakly contractible.

**Proof.** By omitting those factors \( \Delta^a_i \) where \( a_i = 0 \), we may assume that each \( a_i \) is positive. For \( 1 \leq i \leq n \), let \( P_i \subseteq P \) denote the subset consisting of those simplices \( \sigma \subseteq K \) such that the projection map \( K \to \Delta^a_i \) does not carry \( \sigma \) to the final vertex of \( \Delta^a_i \). For \( I \subseteq \{1, \ldots, n\} \), we let \( P_I = \bigcap_{i \in I} P_i \). We will identify each \( N(P_I) \) with a simplicial subset of \( N(P) \). Note that \( N(P_I) = \bigcap_{i \in I} N(P_i) \) and that \( N(P^0) = \bigcup_{1 \leq i \leq n} N(P_i) \). It follows that \( N(P^0) \) can be identified with the homotopy colimit of the diagram \( I \to N(P_I) \), where \( I \) ranges over the collection of nonempty subsets of \( \{1, \ldots, n\} \). To complete the proof, it will suffice to show that each \( N(P_I) \) is weakly contractible.
For every nonempty subset $I \subseteq \{1, \ldots, n\}$, let $K_I$ denote the product
\[
\prod_{i \in I} \Delta^{a_i - 1} \times \prod_{i \notin I} \Delta^{a_i} \subseteq K.
\]
Let $Q_I$ denote the partially ordered collection of nondegenerate simplices of $K_I$. Then $N(Q_I)$ is the barycentric subdivision of $K_I$, and therefore weakly contractible (since $K_I$ is a product of simplices). The inclusion $N(Q_I) \to N(P_I)$ admits a right adjoint, which carries a simplex $\sigma$ to its intersection with the simplicial subset $K_I \subseteq K$. It follows that $N(P_I)$ is also weakly contractible, as desired. \qed

**Lemma 6.3.6.2.** Let $S \to T$ be a surjective map of nonempty finite sets, let $\{\mathcal{E}_s\}_{s \in S}$ be a collection of differentiable pointed $\infty$-categories, $\{\mathcal{D}_t\}_{t \in T}$ a collection of differentiable stable $\infty$-categories, and $\mathcal{E}$ a differentiable stable $\infty$-category. Suppose that we are given a collection of functors
\[
\{F_t : \prod_{s \in S_t} \mathcal{E}_s \to \mathcal{D}_t\}_{t \in T} \quad G : \prod_{t \in T} \mathcal{D}_t \to \mathcal{E}.
\]
Assume that each $F_t$ commutes with sequential colimits, and that $G$ commutes with sequential colimits and is exact in each variable. For each $t \in T$, let $\alpha_t : F_t \to D(F_t)$ be a map which exhibits $D(F_t)$ as a differential of $F_t$. Then the induced map
\[
\alpha : G \circ \prod_{t \in T} F_t \to G \circ \prod_{t \in T} D(F_t)
\]
exhibits $G \circ \prod_{t \in T} D(F_t)$ as a differential of $G \circ \prod_{t \in T} F_t$.

**Proof.** Since the functor $G$ is reduced and right exact in each variable, we have the canonical map $G \circ \prod_{t \in T} F_t \to G \circ \prod_{t \in T} \text{cored}(F_t)$ exhibits $G \circ \prod_{t \in T} \text{cored}(F_t)$ as a coreduction of $G \circ \prod_{t \in T} F_t$. We may therefore replace each $F_t$ by $\text{cored}(F_t)$ and thereby reduce to the case the functors $F_t$ are reduced in each variable. Using Corollary 6.2.3.22, we can write each of the functors $D(F_t)$ as a composition
\[
\prod_{s \in S_t} \mathcal{E}_s \xrightarrow{\Sigma^\infty} \prod_{s \in S_t} \text{Sp}(\mathcal{E}_s) \xrightarrow{\tilde{\partial}(F_t)} \text{Sp}(\mathcal{D}_t) \simeq \mathcal{D}_t
\]
where $\tilde{\partial}(F_t)$ is a multilinear functor, and the map $\alpha_t$ exhibits $\tilde{\partial}(F_t)$ as a derivative of $F_t$. Let $\tilde{\partial}G : \prod_{t \in T} \text{Sp}(\mathcal{D}_t) \to \text{Sp}(\mathcal{E})$ denote a derivative of $G$. Since the $\infty$-categories $\mathcal{D}_t$ and $\mathcal{E}$ are stable and the functor $G$ is exact in each variable, the diagram
\[
\begin{array}{ccc}
\prod_{t \in T} \text{Sp}(\mathcal{D}_t) & \xrightarrow{\tilde{\partial}G} & \text{Sp}(\mathcal{E}) \\
\downarrow{\Omega^\infty} & & \downarrow{\Omega^\infty} \\
\prod_{t \in T} \mathcal{D}_t & \longrightarrow & \mathcal{E}
\end{array}
\]
commutes (up to canonical homotopy). Using Theorem 6.2.1.22, we conclude that $\alpha$ exhibits the composite map
\[
\prod_{s \in S} \text{Sp}(\mathcal{E}_s) \xrightarrow{\prod \tilde{\partial}(F_t)} \prod_{t \in T} \text{Sp}(\mathcal{D}_t) \xrightarrow{\tilde{\partial}G} \text{Sp}(\mathcal{E})
\]
as a derivative of $G \circ \prod_{t \in T} F_t$. It follows from Corollary 6.2.3.24 that $\alpha$ also exhibits $G \circ \prod_{t \in T} D(F_t)$ as a differential of $G \circ \prod_{t \in T} F_t$. \qed

**Proof of Theorem 6.3.2.3.** Let $q : \mathcal{C} \to \Delta^2 \times N(\text{Fin}_*)$ be a thin $\Delta^2$-family of $\infty$-operads satisfying the following conditions:
6.3. THE CHAIN RULE

(1) Each of the ∞-categories $C_i$ is pointed and compactly generated.

(2) For every $i \leq j$, each of the induced functors $C_i^j \to C_j$ preserves final objects and filtered colimits.

(3) Let $i \in \Delta^2$ be a vertex and $\alpha : \langle m \rangle \to \langle n \rangle$ be an injective map of pointed finite sets. If $\pi$ is a locally $q$-coCartesian morphism in $C_\otimes$ lifting the map $\langle i, \langle m \rangle \rangle \to \langle i, \langle n \rangle \rangle$ in $\Delta^2 \times N(\text{Fin}_*)$, then $\pi$ is $q$-coCartesian.

Let $U : \text{Sp}(C)^\otimes \to C^\otimes$ be a map which exhibits $\text{Sp}(C)^\otimes$ as a stabilization of $C^\otimes$. We wish to show that $\text{Sp}(C)^\otimes$ is also a thin $\Delta^2$-family of ∞-operads.

Let us regard the canonical map $U^{op} : (\text{Sp}(C)^\otimes)^{op} \to (C^\otimes)^{op}$ as giving a diagram $v : [1] \to \text{Set}_\Delta$, and let $M$ denote the relative nerve $N_v(\Delta^1)^{op}$ (see Definition T.3.2.5.2). We have a canonical map $u_0 : M \to \Delta^1$, whose fibers are given by $M_0 = C^\otimes$, $M_1 = \text{Sp}(C)^\otimes$. Let $v_0 : [1] \to \text{Set}_\Delta$ be the constant functor taking the value $\Delta^2 \times N(\text{Fin}_*)$. Since the maps

$$C^\otimes \to \Delta^2 \times N(\text{Fin}_*) \quad \text{Sp}(C)^\otimes \to \Delta^2 \times N(\text{Fin}_*)$$

are categorical fibrations, the map $u_0$ lifts to a categorical fibration

$$u : M = N_v(\Delta^1)^{op} \to N_{v_0}(\Delta^1)^{op} \simeq \Delta^2 \times N(\text{Fin}_*) \times \Delta^1$$

(see Lemma T.3.2.5.11).

For every object $A = (j, \langle n \rangle) \in \Delta^2 \times N(\text{Fin}_*)$, the forgetful functor $\text{Sp}(C)^\otimes_A \to C^\otimes_A$ can be identified with a product of $n$ copies of the forgetful functor $\Omega_{C^\otimes_j} : \text{Sp}(C)_j \to C_j$, and therefore admits a left adjoint $\Sigma_A^\infty : C^\otimes_A \to \text{Sp}(C)^\otimes_A$. It follows that $u$ restricts to a coCartesian fibration $u_A : M_A \to \{A\} \times \Delta^1$. In particular, for every object $X \in C^\otimes_A$, we can choose a locally $u$-coCartesian morphism $\alpha : X \to \Sigma_A^\infty(X)$ in $M$ which covers the canonical map $(A, 0) \to (A, 1)$ in $\Delta^2 \times N(\text{Fin}_*) \setminus \Delta^1$.

We first prove:

(i) Suppose we are given a locally $q$-coCartesian morphism $\beta : X' \to X$ in $C^\otimes$, where $X \in C^\otimes_A$ for some $A \in \Delta^2 \times N(\text{Fin}_*)$. Let $\alpha_X : X \to \Sigma_A^\infty(X)$ be defined as above. Then $\alpha_X \circ \beta$ is a locally $u$-coCartesian morphism in $M$.

To prove (i), let $\beta_0 : A' \to A$ denote the image of $\beta$ in $\Delta^2 \times N(\text{Fin}_*)$. Fix an object $Y \in \text{Sp}(C)^\otimes_A$. Let $\text{Map}_{C^\otimes_A}^\alpha(X', Y)$ denote the inverse image of $u(\alpha_X \circ \beta)$ in the mapping space $\text{Map}_M(X', Y)$. We wish to show that composition with $\alpha_X \circ \beta$ induces a homotopy equivalence

$$\xi : \text{Map}_{C^\otimes_A}(\Sigma_A^\infty(X), Y) \to \text{Map}_{C^\otimes_A}^\beta(X', Y).$$

Using the definition of $\Sigma_A^\infty$ and of the ∞-category $M$, we can identify $\xi$ with the map

$$\text{Map}_{C^\otimes_A}(X, U(Y)) \to \text{Map}_{C^\otimes_A}(X', U(Y))$$

given by composition with $\beta$. The desired result now follows from the fact that $\beta$ is locally $q$-coCartesian.

Using (i), we next prove the following:

(ii) The map $u : M \to \Delta^2 \times N(\text{Fin}_*) \times \Delta^1$ is a locally coCartesian fibration.

To prove this, suppose we are given a morphism $\gamma_0 : \langle j', \langle n' \rangle, i' \rangle \to \langle j, \langle n \rangle, i \rangle$ in $\Delta^2 \times N(\text{Fin}_*) \times \Delta^1$ and an object $X' \in M$ lying over $\langle j', \langle n' \rangle, i' \rangle$. We wish to show that $\gamma$ can be lifted to a locally $u$-coCartesian morphism $\gamma : X' \to Y$ in $M$. If $i = i'$, then the desired result follows from the fact that $q : C^\otimes \to \Delta^2 \times N(\text{Fin}_*)$ and $(q \circ U) : \text{Sp}(C)^\otimes \to \Delta^2 \times N(\text{Fin}_*)$ are locally coCartesian fibrations. Let us therefore assume that $i' = 0$ and $i = 1$. In this case, $\gamma_0$ factors as a composition

$$\langle j', \langle n' \rangle, 0 \rangle \xrightarrow{\beta} \langle j, \langle n \rangle, 0 \rangle \xrightarrow{\alpha} \langle j, \langle n \rangle, 1 \rangle.$$
Since \( q \) is a locally coCartesian fibration, we can choose a locally \( q \)-coCartesian morphism \( \beta : X' \to X \) lifting \( \beta_0 \). Let \( \alpha_X : X \to \Sigma_{(i'_j, n)} X \) be as above. It follows from (i) that the composition \( \alpha_X \circ \beta \) is a locally \( u \)-coCartesian morphism lifting \( \gamma \).

Fix an integer \( n \geq 1 \) and let \( S = \{1, \ldots, n\} \). Let \( T = \Delta^2 \times N(\text{Fin}_n) \). Then \( T \) contains objects \( t = (0, (n)) \) and \( t' = (2, (1)) \). Let \( \chi : \text{Part}(S) \to \Delta^t_{t'} \) be as in Notation 6.3.2.11, and let \( \theta : N(\Delta_{t'}^t) \to \text{Fun}(\text{Sp}(\mathcal{E})^\otimes_{(0, (n))}, \text{Sp}(\mathcal{E})) \) be the spray associated to the locally coCartesian fibration \( (q \circ U) : \text{Sp}(\mathcal{E})^\otimes \to N(\text{Fin}_n) \times \Delta^2 \). To prove that \( \text{Sp}(\mathcal{E})^\otimes \) is thin, we must show that the composite map

\[
\phi : N(\text{Part}^0(S))^g \cong N(\text{Part}(S)) \xrightarrow{\Delta} N(\Delta_{t'}^t) \xrightarrow{\theta} \text{Fun}(\text{Sp}(\mathcal{E})^\otimes_{(0, (n))}, \text{Sp}(\mathcal{E}))
\]

is a limit diagram in the \( \infty \)-category \( \text{Fun}(\text{Sp}(\mathcal{E})^\otimes_{(0, (n))}, \text{Sp}(\mathcal{E})) \). Note that \( \phi \) takes values in the full subcategory of \( \text{Fun}(\text{Sp}(\mathcal{E})^\otimes_{(0, (n))}, \text{Sp}(\mathcal{E})) \) spanned by those maps which correspond to functors \( \text{Sp}(\mathcal{E})^n \to \text{Sp}(\mathcal{E}) \) which are excisive in each variable and commute with filtered colimits. Using Theorem 6.2.3.21, we are reduced to showing that the composite map

\[
\phi' : N(\text{Part}(S)) \xrightarrow{\Delta} \text{Fun}(\text{Sp}(\mathcal{E})^\otimes_{(0, (n))}, \text{Sp}(\mathcal{E})) \to \text{Fun}(\text{Sp}(\mathcal{E})^n, \text{Sp}(\mathcal{E}))
\]

is a limit diagram, where the second map is given by composition with the functor

\[
\text{Sp}(\mathcal{E})^n \xrightarrow{\Sigma_{\mathcal{E}}} \text{Sp}(\mathcal{E})^n \cong \text{Sp}(\mathcal{E})_{(0, (n))}^\otimes.
\]

Set \( T^+ = \Delta^2 \times N(\text{Fin}_n) \times \Delta^1 \), so that \( T^+ \) contains objects \( t^+ = (0, (n), 0) \) and \( t'^+ = (2, (1), 1) \). Let \( \mathcal{U} \subseteq \text{Equiv}(S) \) be a downward-closed subset (that is, if an equivalence relation \( E \) on \( S \) belongs to \( \mathcal{U} \), then any finer equivalent relation also belongs to \( \mathcal{U} \)). We define a functor \( \chi_{\mathcal{U}} : \text{Part}(S) \to \Delta^t_{t'^+} \) as follows. To every chain of equivalence relations \( (E_1 \subseteq \cdots \subseteq E_k) \) on \( S \), \( \chi_{\mathcal{U}} \) assigns the \( (k + 1) \)-simplex of \( T^+ \) given by the chain of morphisms

\[
(0, (n), 0) \to (1, (S/E_1)_*, i_1) \to (1, (S/E_2)_*, i_2) \to \cdots \to (1, (S/E_k)_*, i_k) \to (2, (1), 1),
\]

where

\[
i_j = \begin{cases} 
0 & \text{if } E_j \in \mathcal{U} \\
1 & \text{if } E_j \notin \mathcal{U}.
\end{cases}
\]

Let \( \chi' : \text{Part}(S) \to \Delta^t_{t'^+} \) be the functor which carries a chain of equivalence relations \( (E_1 \subseteq \cdots \subseteq E_k) \) to the \( (k + 2) \)-simplex of \( T^+ \) given by the chain of morphisms

\[
(0, (n), 0) \to (0, (n), 1) \to (1, (S/E_1)_*, 1) \to (1, (S/E_2)_*, 1) \to \cdots \to (1, (S/E_k)_*, 1) \to (2, (1), 1),
\]

Let \( \theta^+ : N(\Delta^t_{t'^+}) \to \text{Fun}(\text{Sp}(\mathcal{E})^n, \text{Sp}(\mathcal{E})) \) be the functor obtained by combining the equivalence \( \text{Sp}(\mathcal{E})^n \cong \text{Sp}(\mathcal{E})_{(0, (n))}^\otimes \) with the spray associated to the locally coCartesian fibration \( u \). Unwinding the definition, we can identify \( \phi' \) with the composition \( \theta^+ \circ \chi' \). For every downward closed subset \( \mathcal{U} \subseteq \text{Equiv}(S) \), we let \( \phi_{\mathcal{U}} \) denote the composite map

\[
N(\text{Part}(S)) \xrightarrow{\chi_{\mathcal{U}}} N(\Delta^t_{t'^+}) \xrightarrow{\theta^+} \text{Fun}(\text{Sp}(\mathcal{E})^n, \text{Sp}(\mathcal{E})).
\]

Let \( D : \text{Fun}(\text{Sp}(\mathcal{E})^n, \text{Sp}(\mathcal{E})) \to \text{Exc}_*(\text{Sp}(\mathcal{E}), \text{Sp}(\mathcal{E})) \) be a left adjoint to the inclusion, given by the differentiation construction described in §6.2.3. We have an evident natural transformation \( \chi_{\mathcal{U}} \to \chi' \) of functors from \( \text{Part}(S) \) into \( \Delta^t_{t'^+} \), which induces a natural transformation \( \iota : \phi_{\mathcal{U}} \to \phi' \). Since \( \phi' \) takes values in the full subcategory \( \text{Exc}_*(\text{Sp}(\mathcal{E})^n, \text{Sp}(\mathcal{E})) \), \( \iota \) induces a map \( D \circ \phi_{\mathcal{U}} \to \phi' \). Using Lemma 6.3.6.2, we deduce that this map is an equivalence: that is, for every chain of equivalence relations \( \overline{E} = (E_1 \subseteq \cdots \subseteq E_k) \) in \( \text{Part}(S) \), the map \( \iota_{\overline{E}} : \phi_{\mathcal{U}}(\overline{E}) \to \phi'(\overline{E}) \) exhibits \( \phi'(\overline{E}) \) as a differential of \( \phi_{\mathcal{U}}(\overline{E}) \). We will deduce that \( \phi' \) is a limit diagram from the following more general assertion:
6.3. THE CHAIN RULE

(iii) For every downward-closed \( U \subseteq \text{Equiv}(S) \), the composition \( D \circ \phi_U \) determines a limit diagram

\[
\text{N}(\text{Part}(S)) \to \text{Exc}_*(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)).
\]

The proof of (iii) proceeds by descending induction on the cardinality of \( U \). Our base case is the following:

(iv) If \( U = \text{Equiv}(S) \), then the functor \( D \circ \phi_U \) determines a limit diagram \( \text{N}(\text{Part}(S)) \to \text{Exc}_*(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) \).

To carry out the inductive step, we will prove the following:

(v) Let \( U \subseteq \text{Equiv}(S) \) be a proper downward closed subset. Let \( E \) be an equivalence relation on \( S \) which is minimal among those elements which does not belong to \( U \), let \( U' = U \cup \{ E \} \), and assume that \( D \circ \phi_{U'} \) is a limit diagram in \( \text{Exc}_*(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) \). Then \( D \circ \phi_U \) is a limit diagram in \( \text{Exc}_*(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) \).

We now prove (iv). Let \( \theta^* : (\Delta^n)^* \to \text{Fun}(\mathbb{C}^n_{(n)}, \mathbb{C}_2) \) be the spray associated to the locally coCartesian fibration \( q : \mathbb{C}^\otimes \to T \), and let \( \Sigma^\infty_{\mathbb{C}_2} : \mathbb{C}_2 \to \text{Sp}(\mathbb{C}_2) \) be a left adjoint to the functor \( \text{Sp}(\mathbb{C}_2) \to \mathbb{C}_2 \) determined by \( p \). Using (i), we deduce that \( \phi_{\text{Equiv}(S)} \) is equivalent to the composition

\[
\text{N}(\text{Part}(S)) \xrightarrow{\psi} \text{Fun}(\mathbb{E}_0^n, \mathbb{C}_2) \xrightarrow{\psi^*} \text{Fun}(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)),
\]

where \( \psi \) denotes the composition

\[
\text{N}(\text{Part}(S)) \xrightarrow{\psi} \text{N}(\Delta_{T}^{\otimes n}) \xrightarrow{\theta^*} \text{Fun}(\mathbb{C}^n_{(n)}, \mathbb{C}_2) \simeq \text{Fun}(\mathbb{E}_0^n, \mathbb{C}_2).
\]

Let \( D' : \text{Fun}(\mathbb{E}_0^n, \mathbb{C}_2) \to \text{Exc}_*(\mathbb{E}_0^n, \mathbb{C}_2) \) be a left adjoint to the inclusion. The commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\text{Exc}_*(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) & \xrightarrow{\Omega^\infty_{\mathbb{C}_2} \circ} & \text{Exc}_*(\mathbb{E}_0^n, \mathbb{C}_2) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) & \xrightarrow{\Omega^\infty_{\mathbb{C}_2} \circ} & \text{Fun}(\mathbb{E}_0^n, \mathbb{C}_2)
\end{array}
\]

determines a commutative diagram of left adjoint functors

\[
\begin{array}{ccc}
\text{Exc}_*(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) & \xleftarrow{D} & \text{Exc}_*(\mathbb{E}_0^n, \mathbb{C}_2) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) & \xleftarrow{\Sigma^\infty_{\mathbb{C}_2}} & \text{Fun}(\mathbb{E}_0^n, \mathbb{C}_2)
\end{array}
\]

where the upper horizontal map is an equivalence by virtue of Proposition 1.4.2.22. Consequently, to show that \( D \circ \phi_{\text{Equiv}(S)} \simeq D \circ \Sigma^\infty_{\mathbb{C}_2}(\psi) \) is a limit diagram in \( \text{Exc}_*(\mathbb{E}_0^n, \text{Sp}(\mathbb{C}_2)) \), it will suffice to show that \( D' \circ \psi \) is limit diagram in \( \text{Exc}_*(\mathbb{E}_0^n, \mathbb{C}_2) \). Using Corollary 6.2.3.24, we are reduced to proving that the diagram \( \tilde{D} \circ \psi \) is a limit diagram in \( \text{Exc}_*(\text{Sp}(\mathbb{C}_2)^n, \text{Sp}(\mathbb{C}_2)) \). We will prove this by verifying the hypotheses of Theorem 6.3.5.5. Fix an equivalence relation \( E \) on \( S \). We let \( \text{Equiv}_E(S) \) denote the subset of \( \text{Equiv}(S) \) spanned by those equivalence relations \( E' \) on \( S \) which refine \( E \). We have a canonical isomorphism of partially ordered sets

\[
\text{Equiv}_E(S) = \prod_{S' \in S/E} \text{Equiv}(S'),
\]

where the product is taken over all equivalence classes in \( S \) (which we regard as subsets of \( S \)). The inclusion \( \text{Equiv}_E(S) \hookrightarrow \text{Equiv}(S) \) admits a right adjoint, which we can identify with the map

\[
\eta : \text{Equiv}(S) \to \prod_{S' \in S/E} \text{Equiv}(S'),
\]

given by restricting an equivalence relation on \( S \) to each of the subsets \( S' \in S/E \). Composing with \( \eta \) gives a map \( \gamma : \text{Part}(S) \to \prod_{S' \in S/E} \text{Part}(S') \). We first verify:
(a) The map \( u \) restricts to a right cofinal map \( \text{Part}^0(S) \to \Pi_{S' \in S/E} \text{Part}^0(S') \). According to Theorem T.4.1.3.1, this is equivalent to the assertion that for every element \( \{X_{S'}\}_{S' \in S/E} \in \prod_{S' \in S/E} \text{Part}^0(S') \), the partially ordered set \( P = \{ X \in \text{Part}^0(S) : \gamma(X) \leq \{X_{S'}\} \} \) has weakly contractible nerve.

We can identify each \( X_{S'} \) with a nondegenerate simplex in \( \text{N}(\text{Equiv}(S')) \). Unwinding the definitions, we see that the simplicial set \( N(P) \) is isomorphic to the barycentric subdivision of the simplicial set \( Q = \text{N}(\text{Equiv}(S)) \times \prod_{S' \in S/E} \text{N}(\text{Equiv}(S')) \times \prod_{S'' \in S/E} X_{S''} \), which is a full subcategory of \( \text{N}(\text{Equiv}(S)) \).

Let \( Q_0 \) denote the full subcategory of \( Q \) spanned by those equivalence relations on \( S \) which refine \( E \). The inclusion \( Q_0 \hookrightarrow Q \) admits a right adjoint and is therefore a weak homotopy equivalence. We are therefore reduced to proving that \( Q_0 \) is weakly contractible. It now suffices to observe that the projection map \( Q_0 \to \prod_{S' \in S/E} X_{S'} \) is an isomorphism, so that \( Q_0 \) is a product of simplices.

For each \( S' \in S/E \), let \( t_{S'} = (0, S'_0) \in T \), let \( \theta_{S'} : N(\Delta^{t_{S'}, t'}) \to \text{Fun}(\mathcal{E}_{0, S'_0}, \mathcal{C}) \) be the spray associated to the locally coCartesian fibration \( q \). Composing with the functor \( \text{Part}(S') \to N(\Delta^{t_{S'}, t'}) \) and using the identification \( \mathcal{E}_{0, S'_0} \simeq \mathcal{E}_0^S \), we obtain a map \( \psi_{S'} : N(\text{Part}(S')) \to \text{Fun}(\mathcal{E}_0^S, \mathcal{C}_2) \). Using (3), we see that the composite map

\[
\text{N}(\text{Part}(S)) \to \text{N}(\text{Part}(S')) \xrightarrow{\psi_{S'}} \text{Fun}(\mathcal{E}_0^s, \mathcal{C}_2)
\]

is given by composing the functor \( \psi : N(\text{Part}(S)) \to \text{Fun}(\mathcal{E}_0^S, \mathcal{C}_2) \) with the map \( \text{Fun}(\mathcal{E}_0^S, \mathcal{C}_2) \to \text{Fun}(\mathcal{E}_0^E, \mathcal{C}_2) \) determined by the inclusion

\[
\mathcal{E}_{0}^{S'} \simeq \prod_{s \in S'} \mathcal{E}_0 \times \prod_{s \in S-S'} \{ * \} \subseteq \mathcal{E}_0^S,
\]

where \(*\) denotes a zero object of \( \mathcal{C}_0 \) (see Remark 6.3.2.4).

To complete the verification of the hypotheses of Theorem 6.3.5.5, it suffices to observe the following:

(b) Each of the functors \( \psi_{S'} \to N(\text{Part}(S')) \to \text{Fun}(\mathcal{E}_{0}^{S'}, \mathcal{C}_2) \) is a limit diagram.

This follows immediately from our assumption that the corepresentable \( \Delta^2\)-family of \( \infty\)-operads \( 0^\infty \to N(\text{Fin}_*) \times \Delta^2 \) is thin.

We now prove (v). Let \( \mathcal{U} \subseteq \text{Equiv}(S) \) be a downward closed subset, let \( E \) be a minimal element of \( \text{Equiv}(S) - \mathcal{U} \), let \( \mathcal{U}' = \mathcal{U} \cup \{E\} \), and assume that \( D \circ \phi_{\mathcal{U}} \) is a limit diagram. We wish to prove that \( D \circ \phi_{\mathcal{U}} \) is a limit diagram.

We define a functor

\[
\chi_{\mathcal{U}, \mathcal{U}'} : \text{Part}(S) \to \Delta^{t^+, t^+}
\]

as follows. If \( \bar{E} = (E_1 \subseteq \cdots \subseteq E_k) \) is a chain of equivalence relations on \( S \) which does not contain the equivalence relation \( E \), then we set \( \chi_{\mathcal{U}, \mathcal{U}'}(\bar{E}) = \chi_{\mathcal{U}}(\bar{E}) = \chi_{\mathcal{U}'}(\bar{E}) \). Otherwise, there is a unique integer \( p \leq k \) such that \( E_p = E \). We define \( \chi_{\mathcal{U}, \mathcal{U}'}(J) \) to be the simplex of \( T^+ \) given by the chain of morphisms

\[
(0, \langle n \rangle, 0) \to (1, (S/E_1)_*, 0) \\
\to \cdots \\
\to (1, (S/E_p)_*, 0) \\
\to (1, (S/E_p)_*, 1) \\
\to \cdots \\
\to (1, (S/E_k)_*, 1) \\
\to (2, \langle 1 \rangle, 1).
\]

Composing with \( \theta^+ \), we obtain a functor \( \phi_{\mathcal{U}, \mathcal{U}'} : N(\text{Part}(S)) \to \text{Fun}(\mathcal{E}_0^n, \text{Sp}(\mathcal{C}_2)) \). Moreover, we have evident natural transformations \( \chi_{\mathcal{U}} \to \chi_{\mathcal{U}, \mathcal{U}'} \leftarrow \chi_{\mathcal{U}'} \), which induce natural transformations

\[
\phi_{\mathcal{U}} \to \phi_{\mathcal{U}, \mathcal{U}'} \leftarrow \phi_{\mathcal{U}'}.
\]
Using (i), we deduce that the map $\epsilon$ is an equivalence. Consequently, to complete the proof of (v), it will suffice to show that $D \circ \phi_{U, U'}$ is a limit diagram.

Let $P \subseteq [1] \times \text{Part}(S)$ be the subset consisting of those pairs $(i, \vec{E})$ where either $i = 0$ or $\vec{E}$ contains $E$. We define a map $\chi_P : P \to \Delta^{i_+, i^+}$ by the formula

$$
\chi_P(i, \vec{E}) = \begin{cases} 
\chi_{U, U'}(\vec{E}) & \text{if } i = 1 \\
\chi_U(\vec{E}) & \text{otherwise}.
\end{cases}
$$

Note that composition with $\theta^+$ determines a map $\phi_P : N(P) \to \text{Fun}(\mathbb{E}^n_0, \text{Sp}(\mathbb{E})_2)$. Let $P^0$ denote the partially ordered subset of $P$ obtained by removing the least element $(0, \emptyset)$. By assumption, the restriction of $D \circ \phi_P$ to $N(\{0\} \times \text{Part}(S))$ is a limit diagram. The inclusion $N(\{0\} \times \text{Part}^0(S)) \hookrightarrow N(P^0)$ admits a right adjoint (given by the projection $P^0 \to \text{Part}^0(S)$) and is therefore right cofinal. It follows that $D \circ \phi_P$ is a limit diagram.

Define partially ordered subsets $P'' \subseteq P' \subseteq P$ as follows:

- A pair $(i, \vec{E}) \in P$ belongs to $P'$ if either $i = 1$ or $\vec{E}$ does not contain $E$ as a least element.

- A pair $(i, \vec{E}) \in P$ belongs to $P''$ if either $i = 1$ or $\vec{E}$ does not contain $E$.

Set $P^0 = P' \cap P^0$ and $P'' = P'' \cap P^0$. Note that the projection map $P'' \to \text{Part}(S)$ is an isomorphism of partially ordered sets, and that the restriction of $\phi_P$ to $N(P'')$ coincides with $\phi_{U, U'}$. To complete the proof, it will suffice to show that the restriction of $D \circ \phi_P$ to $N(P'')$ is a limit diagram. The inclusion $N(P'') \to N(P^0)$ admits a right adjoint (given by $(i, \vec{E}) \mapsto \begin{cases} (0, \vec{E} - \{E\}) & \text{if } i = 0 \\
(1, \vec{E}) & \text{if } i = 1. \end{cases}$), and is therefore right cofinal. We are therefore reduced to proving that the restriction of $D \circ \phi_P$ to $N(P'')$ is a limit diagram. Since $D \circ \phi_P$ is a limit diagram, this is a consequence of the following assertion:

(vi) The diagram $D \circ \phi_P$ is a right Kan extension of its restriction to $N(P')$.

To prove (vi), fix an object $(0, \vec{E}) \in P - P'$; we will show that $D \circ \phi_P$ is a right Kan extension of $(D \circ \phi_P)|N(P')$ at $(0, \vec{E})$. We can identify $\vec{E}$ with a chain of equivalence relations

$$E = E_0 \subseteq E_1 \subseteq \cdots \subseteq E_k$$

on $S$. Let $P'_{\vec{E}_i} = \{(i, \vec{E}') \in P' : \vec{E} \subseteq \vec{E}'\}$. We wish to prove that the canonical map

$$D(\phi_P(0, \vec{E})) \to \lim_{(i, \vec{E}') \in P'_{\vec{E}_i}} D(\phi_P(i, \vec{E}'))$$

is an equivalence. Let $Q \subseteq P'_{\vec{E}_i}$ be the partially ordered subset spanned by those pairs $(i, \vec{E}')$, where $\vec{E}' \cap \{E' \in \text{Equiv}(S) : E \subseteq E'\} = \vec{E}$. The construction $(i, \vec{E}') \mapsto (i, \vec{E} - \{E' \in \text{Equiv}(S) : E \subseteq E' \notin \vec{E}\})$ determines a right adjoint to the inclusion $Q \hookrightarrow P'_{\vec{E}_i}$, so that the inclusion $N(Q) \to N(P'_{\vec{E}_i})$ is right cofinal. It will therefore suffice to prove that the canonical map

$$D(\phi_P(0, \vec{E})) \to \lim_{(i, \vec{E}') \in Q} D(\phi_P(i, \vec{E}'))$$

is an equivalence.

Let $\text{Part}'(S)$ denote the subset of $\text{Part}(S)$ consisting of those linearly ordered subsets of $\text{Equiv}(S)$ which contain $E$ as a largest element. The construction $\vec{E} \mapsto \vec{E}' \cup \vec{E}$ induces a bijection from $\text{Part}'(S)$ to the subset of $\text{Part}(S)$ consisting of those chains which contain $\vec{E}$ as a final segment. Let $\text{Part}^0(S)$ denote the
Let \( t'' \) denote the vertex \( (1, (S/E)_*) \) of \( \Delta^2 \times N(Fin_*) \). The locally coCartesian fibration \( q : \mathcal{C}^\otimes \to \Delta^2 \times N(Fin_*) \) determines a spray \( \hat{\theta} : N(\Delta^2_{T''}) \to \text{Fun}(\mathcal{C}_{0,(n)_*}, \mathcal{C}_{1,(S/E)_*}) \). Let \( \chi'' : \text{Part}'(S) \to \Delta^2_{T''} \) be the map which carries a chain of equivalence relations

\[
E'_0 \subseteq E'_1 \subseteq \cdots \subseteq E'_k = E
\]
to the simplex corresponding to the chain of maps

\[
t = (0, (n)) \to (1, (S/E'_0)_*) \to \cdots \to ((S/E'_k)_*, 1).
\]

Composing \( \chi'' \) and \( \hat{\theta} \) and using the identifications \( \mathcal{C}_{0,(n)_*} \simeq \mathcal{C}_0^n \) and \( \mathcal{C}_{1,(S/E)_*} \simeq \mathcal{C}_{1S/E}^1 \), we obtain a diagram \( \psi_E : N(\text{Part}'(S)) \to \text{Fun}(\mathcal{C}_{00}, \mathcal{C}_{1S/E}) \).

For every nonempty subset \( S' \subseteq S \), let \( E_{S'} \) denote the restriction of the equivalence relation \( E \) to \( S' \), and let \( \text{Part}'(S') \) denote the subset of \( \text{Part}(S') \) consisting of those linearly ordered subsets of \( \text{Equiv}(E) \) which contain \( E_{S'} \) as a maximal element. Consider the vertices \( t_{S'} = (0, S'_0) \) and \( t_{S'}' = (1, 1) \) of \( T \), and let \( \hat{\theta}_{S'} : N(\Delta_{T''}^2) \to \text{Fun}(\mathcal{C}_{00,S'_0}, \mathcal{C}_1) \) be the spray associated to the locally coCartesian fibration \( q : \mathcal{C}^\otimes \to T \). Let \( \chi_{S'} : \text{Part}'(S') \to \Delta_{T''}^2 \) be the functor which carries a chain of equivalence relations

\[
E'_0 \subseteq E'_1 \subseteq \cdots \subseteq E'_k
\]
to the simplex given by the chain of maps

\[
t_E = (0, S'_0) \to (1, (S'/E'_0)_*) \to \cdots \to (1, (S'/E'_k)_*).
\]

Composing \( \chi_{S'} \) and \( \hat{\theta}_{S'} \), we obtain a functor \( \psi_{S'} : N(\text{Part}'(S')) \to \text{Fun}(\mathcal{C}_{00}, \mathcal{C}_1) \). The inclusion \( S' \hookrightarrow S \) determines a map \( \text{Equiv}(S) \to \text{Equiv}(S') \), which induces a restriction map \( r_{S'} : \text{Part}'(S) \to \text{Part}'(S') \). Unwinding the definitions, we see that \( \psi_E \) is equivalent to the composition

\[
N(\text{Part}'(S)) \xrightarrow{\prod_{S' \in S/E} r_{S'}} \prod_{S' \in S/E} N(\text{Part}'(S')) \xrightarrow{\prod_{S' \in S/E} \psi_{S'}} \prod_{S' \in S/E} \text{Fun}(\mathcal{C}_{00}, \mathcal{C}_1) \to \text{Fun}(\mathcal{C}_{00}, \mathcal{C}_{1S/E}).
\]

We now divide the proof into two cases. Suppose first that \( k = 0 \), so that \( \bar{E} = \{ E \} \). The edge \( (1, (S/E)_*) \to (2, (1)) \) of \( T \) determines a functor \( G : \mathcal{C}_{1S/E}^0 \to \mathcal{C}_2 \). Unwinding the definitions, we obtain canonical equivalences

\[
\phi_P(0, \bar{E}' \cup \bar{E}) \simeq \Sigma_{\mathcal{C}_2^0} \circ G \circ \prod_{S' \in S/E} \psi_{S'}(r_{S'} \bar{E}')
\]
\[
\phi_P(1, \bar{E}' \cup \bar{E}) \simeq \delta(G) \circ \prod_{S' \in S/E} \Sigma_{\mathcal{C}_1^0} \circ \psi_{S'}(r_{S'} \bar{E}').
\]
6.3. THE CHAIN RULE

To prove that $\sigma$ is a pullback diagram, it will suffice to show that the square

$$
\begin{array}{ccc}
\tilde{\delta}(G \circ \prod_{S' \in S/E} (\psi_{S'} \circ r_{S'})) \{E\}) & \to & \left( \lim_{E' \in \text{Part}^{\text{eq}}(S)} \tilde{\delta}(G \circ \prod_{S' \in S/E} (\psi_{S'} \circ r_{S'}))(E') \right) \\
\tilde{\delta}(G \circ \prod_{S' \in S/E} (\psi_{S'} \circ r_{S'})) \{E\}) & \to & \left( \lim_{E' \in \text{Part}^{\text{eq}}(S)} \tilde{\delta}(G \circ \prod_{S' \in S/E} (\psi_{S'} \circ r_{S'}))(E') \right)
\end{array}
$$

is a pullback square in $\text{Exc}_{\ast}(\text{Sp}(\mathbb{C}_0)^{\ast}, \text{Sp}(\mathbb{C}_2))$. We will deduce this from Theorem 6.3.5.6.

Choose an equivalence relation $E' \subseteq E$ on $S$. If $S' \subseteq S$, we let $E_{S'}$ denote the restriction of the equivalence relation $E'$ to $S'$. Unwinding the definitions, we see that for each $S' \subseteq S/E$ and each $E' \in \text{Part}'(S)$, the functor $(\psi_{S'} \circ r_{S'})(E')_{E/S'}$ canonically equivalent to the composition

$$
E' \subseteq S/E \ni \{v\} \quad \mapsto \quad \partial_{S'/E'}(\psi_{S'}(\{v\})) \in \text{Part}'(S)
$$

where the final functor is given by the iterated product. To satisfy the hypotheses of Theorem 6.3.5.6, it will suffice to verify the following:

(vii) The restriction maps $r_{S''}$ determine a right cofinal map $N(\text{Part}^{\text{eq}}(S)) \to \prod_{S'' \in S/E'} N(\text{Part}'(S''))$.

Fix elements $\{E'_i \in \text{Part}'(S'')\}$ for $S'' \subseteq S/E'$. Let $\text{Part}^{\text{eq}}(S)$ denote the subset of $\text{Part}^{\text{eq}}(S)$ consisting of those elements $E'$ such that $r_{S''}(E') \subseteq E'_i$, for $S'' \subseteq S/E'$. According to Theorem T.4.1.3.1, it will suffice to show that the partially ordered set $\text{Part}^{\text{eq}}(S)$ has weakly contractible nerve.

Let $\text{Equiv}_{E'}(S)$ denote the subset of $\text{Equiv}(S)$ consisting of equivalence relations which refine $E'$, and define $\text{Equiv}_{E'}(S) \subseteq \text{Equiv}_E(S)$ similarly. For every downward-closed subset $V \subseteq \text{Equiv}_E(S) - \{(E) \cup \text{Equiv}_{E'}(S)\}$, we let $\text{Part}^{\text{eq}}_{V'}(S)$ denote the subset of $\text{Part}^{\text{eq}}(S)$ consisting of those linearly ordered subsets $E'' \subseteq \text{Equiv}(S)$ which do not intersect $V$. We will prove that $\text{Part}^{\text{eq}}_{V'}(S)$ has a weakly contractible nerve by descending induction on the cardinality of $V$. Taking $V = \emptyset$, this will complete the proof of (vi). We first treat the base case $V = \text{Equiv}_E(S) - \{(E) \cup \text{Equiv}_{E'}(S)\}$ Let $R$ denote the subset of $\text{Part}^{\text{eq}}_{V'}(S)$ consisting of those subsets $E'' \subseteq \text{Equiv}(S)$ which contain $E'$. The inclusion $R \subseteq \text{Part}^{\text{eq}}_{V'}(S)$ admits a left adjoint, given by $E'' \mapsto E'' \cup \{E'\}$. It will therefore suffice to show that $N(R)$ is weakly contractible. This is clear, since $R$ contains a least element (given by the linearly ordered subset $\{E' \subseteq E\} \subseteq \text{Equiv}(S)$).

We now carry out the inductive step. Assume that $\text{Part}^{\text{eq}}_{V'}(S)$ has a weakly contractible nerve for some nonempty subset $V \subseteq \text{Equiv}_E(S) - \{(E) \cup \text{Equiv}_{E'}(S)\}$. Let $E''$ be a maximal element of $V$ and let $V' = V - \{E''\}$. We will prove that $\text{Part}^{\text{eq}}_{V'}(S)$ has a weakly contractible nerve by showing that the inclusion

$$
i : N(\text{Part}^{\text{eq}}_{V'}(S)) \hookrightarrow N(\text{Part}^{\text{eq}}_{V'}(S))
$$

is a weak homotopy equivalence. Let $R$ denote the subset of $\text{Part}^{\text{eq}}_{V'}(S)$ consisting of those linearly ordered subsets $E'' \subseteq \text{Equiv}(S)$ with the following property: if $E''$ belongs to $E''$, then the common refinement $E' \cap E''$ belongs to $E'$. Then the inclusion map $\iota'$ factors as a composition

$$
N(\text{Part}^{\text{eq}}_{V'}(S)) \xrightarrow{\iota'} N(R) \xrightarrow{\iota''} N(\text{Part}^{\text{eq}}_{V'}(S)).
$$

Here $\iota'$ admits a right adjoint and $\iota''$ admits a left adjoint. It follows that $\iota'$ and $\iota''$ are weak homotopy equivalences, so that $\iota$ is a weak homotopy equivalence. This completes the proof of (vii).

We now return to the proof of (vi) in the case where $k > 0$. Let $W = S/E_1$. Given an element $w \in W$, let $S_w$ denote its inverse image in $S$ and let $E_w$ be the restriction of $E$ to $S_w$. The map of pointed finite sets $(S/E)_w \to W_w$ determines functors

$$
G_w : \prod_{E \in S_w/E} \mathcal{C}_1 \to \mathcal{C}_1
$$
Let \( H : \text{Sp}(\mathcal{C})_1^W \to \text{Sp}(\mathcal{C})_2 \) be the functor given by the composition
\[
\text{Sp}(\mathcal{C})_1^{S/E_1} \to \text{Sp}(\mathcal{C})_1^{S/E_2} \to \cdots \to \text{Sp}(\mathcal{C})_1^{S/E_k} \to \text{Sp}(\mathcal{C})_2
\]
determined by \( \vec{E} \). Unwinding the definitions, we obtain canonical equivalences
\[
\phi_p(0, \vec{E}' \cup \vec{E}) \simeq H \circ \prod_{w \in W} (\Sigma_{\infty} \circ G_w) \circ \prod_{S' \in S_w/E_w} \psi_{S'}(r_{S'} \vec{E}')
\]
\[
\phi_p(1, \vec{E}' \cup \vec{E}) \simeq H \circ \prod_{w \in W} (\delta(G_w)) \circ \prod_{S' \in S_w/E_w} \Sigma_{\infty} \circ \psi_{S'}(r_{S'}(\vec{E}))
\]
for \( \vec{E}' \in \text{Part}'(S) \). Since \( \text{Sp}(\mathcal{C})_1^\circ \) is a stable \( \Delta^2 \)-family of \( \infty \)-operads, the functor \( H \) is exact in each variable. Using Lemma 6.3.6.2 and Corollary 6.2.3.24, we see that \( \sigma \) is a pullback diagram if and only if the diagram
\[
\begin{array}{ccc}
H \circ \prod_{w \in W} \delta(G_w) \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'})(\{E\}) & \overset{\lim_{\vec{E} \in \text{Part}'(S)}}{=} & \\
\overset{\lim_{\vec{E} \in \text{Part}'(S)}}{\lim_{\vec{E} \in \text{Part}'(S)}} H \circ \prod_{w \in W} \delta(G_w) \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'})(\vec{E}) & \overset{\lim_{\vec{E} \in \text{Part}'(S)}}{=} & \\
H \circ \prod_{w \in W} \delta(G_w) \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'})(\vec{E}) & \overset{\lim_{\vec{E} \in \text{Part}'(S)}}{=} & \\
\overset{\lim_{\vec{E} \in \text{Part}'(S)}}{\lim_{\vec{E} \in \text{Part}'(S)}} H \circ \prod_{w \in W} \delta(G_w) \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'})(\vec{E}) & \overset{\lim_{\vec{E} \in \text{Part}'(S)}}{=} & \\
\end{array}
\]
is a pullback square in \( \text{Exc}_*(\text{Sp}(\mathcal{C})_1^\circ, \text{Sp}(\mathcal{C})_2) \).

Define \( F, F' : N(\text{Part}'(S)) \to \text{Exc}_*(\text{Sp}(\mathcal{C})_1^\circ, \text{Sp}(\mathcal{C})_2) \) by the formulae
\[
F(\vec{E}) = H \circ \prod_{w \in W} \delta(G_w) \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'})(\vec{E})
\]
\[
F'(\vec{E}) = H \circ \prod_{w \in W} \delta(G_w) \circ \prod_{S' \in S_w/E_w} \text{Diff}(\psi_{S'} \circ r_{S'})(\vec{E})
\]
We wish to prove that the evident natural transformation \( F \to F' \) induces an equivalence \( \text{tfib}(F) \to \text{tfib}(F') \) in the stable \( \infty \)-category \( \text{Exc}_*(\text{Sp}(\mathcal{C})_1^\circ, \text{Sp}(\mathcal{C})_2) \). To study this map, we need the following observation:
\[\begin{enumerate} \setcounter{enumi}{7} \item \end{enumerate}\]
Let \( (\prod_{w \in W} \text{Part}'(S_w))^0 \) denote the subset of \( (\prod_{w \in W} \text{Part}'(S_w)) \) obtained by removing the least element. Then the restriction maps \( \text{The restriction maps } \{r_{S_w} : \text{Part}'(S) \to \text{Part}'(S_w)\} \) induce a right cofinal functor
\[
N(\text{Part}'^0(S)) \to N(\prod_{w \in W} \text{Part}'(S_w))^0.
\]
To prove (viii), let us fix an element \( \{\vec{E}'_w\}_{w \in W} \) of \( \prod_{w \in W} \text{Part}'(S_w) \) which is not the least element. Using the criterion of Theorem T.4.1.3.1, we are reduced to proving that the partially ordered set \( Z = \{\vec{E}' \in \text{Part}'^0(S) : (\forall w \in W)[r_{S_w}(\vec{E}') \subseteq \vec{E}_w]\} \) has weakly contractible nerve. Let \( Z'' \subseteq \text{Part}(S) \) be the subset consisting of those nonempty chains \( \vec{E}' = (E'_0 \subseteq \cdots \subseteq E'_w) \in \text{Part}(S) \) such that \( E'_k \subseteq E \) and \( r_{S_w}(\vec{E}') \subseteq \vec{E}_w \) for each \( w \in W \), and let \( Z' \subseteq Z'' \) be the subset obtained by removing the one-element chain \( \{E\} \). The inclusion \( Z \to Z' \) has a left adjoint (given by the construction \( \vec{E}' \mapsto \vec{E}' \cup \{E\} \)) and therefore induces a weak homotopy equivalence \( N(Z) \to N(Z') \). We are therefore reduced to proving that \( N(Z') \) is weakly contractible. Note that each \( \vec{E}''_w \) determines an embedding \( \Delta^1 \to \text{Equiv}(S_w) \). Since \( \{\vec{E}'_w\}_{w \in W} \) is not the
least element of $\prod_{w \in W} \text{Part}'(S_w)$, at least one of the integers $a_w$ is nonzero. Unwinding the definitions, we can identify $N(Z')$ with the barycentric subdivision of the product $\prod_{w \in W} \Delta^{a_w}$. The weak contractibility of $N(Z')$ now follows from Lemma 6.3.6.1.

For every subset $S' \subseteq S_w$, we let $r^{w}_{S'} : \text{Part}'(S_w) \to \text{Part}'(S')$ denote the evident restriction map. Define functors $F_w, F'_w : N(\text{Part}'(S_w)) \to \text{Fun}(\text{Sp}(\mathcal{E}_0^n), \text{Sp}(\mathcal{E})_1)$ by the formulae

$$F_w(\tilde{E}_w) = \tilde{\delta}(G_w \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'}^{w})(\tilde{E}_w)) \quad F'_w(\{\tilde{E}_w\}) = \tilde{\delta}(G_w) \circ \prod_{S' \in S_w/E_w} \tilde{\delta}(\psi_{S'} \circ r_{S'}^{w})(\tilde{E}_w).$$

Let

$$F_0 : \prod_{w \in W} N(\text{Part}'(S_w)) \to \text{Fun}(\text{Sp}(\mathcal{E}_0^n), \text{Sp}(\mathcal{E})_2)$$

be given by the formula $F_0(\{\tilde{E}_w\}) = H \circ \prod_{w \in W} F_w(\tilde{E}_w)$, and define $F_0'$ similarly. Then we can recover $F$ and $F'$ as the composite functors

$$\text{Part}'(S) \to \prod_{w \in W} \text{Part}'(S_w) \xrightarrow{F_0'} \text{Fun}(\text{Sp}(\mathcal{E}_0^n), \text{Sp}(\mathcal{E})_2)$$

We have an evident commutative diagram

$$\xymatrix{ \text{tfib } F_0 \ar[r] \ar[d] & \text{tfib } F'_0 \ar[d] \\
\text{tfib } F \ar[r] & \text{tfib } F',}$$

and assertion (viii) guarantees that the vertical maps are equivalences. We are therefore reduced to proving that the map $\rho : \text{tfib } F_0 \to \text{tfib } F'_0$ is an equivalence. Since the functor $H$ is exact in each variable, we can identify $\rho$ with the canonical map $H \circ \prod_{w \in W} \{\text{tfib } F_w\} \to H \circ \prod_{w \in W} \{\text{tfib } F'_w\}$. It will therefore suffice to show that for each $w \in W$, the map $\text{tfib } F_w \to \text{tfib } F'_w$ is an equivalence. Equivalently, we wish to show that the diagram

$$\xymatrix{ \tilde{\delta}(G \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'}^{w})(\{E_w\})) \ar[r] \ar[d] & \lim_{E_w \in \text{Part}'(S_w)} \tilde{\delta}(G \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'}^{w})(\tilde{E}_w)) \ar[d] \\
\tilde{\delta}(G \circ \prod_{S' \in S_w/E_w} ((\psi_{S'} \circ r_{S'}^{w})(\{E_w\})) \ar[r] & \lim_{E_w \in \text{Part}'(S_w)} \tilde{\delta}(G \circ \prod_{S' \in S_w/E_w} (\psi_{S'} \circ r_{S'}^{w})(\tilde{E}_w))}$$

is a pullback square in $\text{Fun}(\text{Sp}(\mathcal{E}_0^n), \text{Sp}(\mathcal{E})_1)$. The proof now proceeds exactly as in the case $k = 0$ (with some minor changes in notation). $\square$
Chapter 7

Algebra in the Stable Homotopy Category

Let $\text{Sp}$ denote the $\infty$-category of spectra. In §4.8.2, we saw that $\text{Sp}$ admits a symmetric monoidal structure (the smash product symmetric monoidal structure) which is characterized up to equivalence by the requirement that the sphere spectrum $S \in \text{Sp}$ is the unit object and the tensor product functor $\otimes : \text{Sp} \times \text{Sp} \to \text{Sp}$ preserves colimits separately in each variable. This operation can be regarded as a homotopy theoretic analogue of the usual tensor product of abelian groups. In this chapter, we will undertake a systematic study of commutative and noncommutative algebra in the $\infty$-category $\text{Sp}$.

We begin in §7.1 by introducing the notion of an $E_k$-ring, for $0 \leq k \leq \infty$. To guide the reader’s intuition, we offer the following table of analogies:

<table>
<thead>
<tr>
<th>Ordinary Algebra</th>
<th>$\infty$-Categorical Algebra</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set</td>
<td>Space</td>
</tr>
<tr>
<td>Abelian group</td>
<td>Spectrum</td>
</tr>
<tr>
<td>Tensor product of abelian groups</td>
<td>Smash product of spectra</td>
</tr>
<tr>
<td>Associative Ring</td>
<td>$E_1$-Ring</td>
</tr>
<tr>
<td>Commutative Ring</td>
<td>$E_\infty$-Ring</td>
</tr>
</tbody>
</table>

Our goal in §7.2 is to show that these analogies are fairly robust, in the sense that many of the basic tools used in commutative and noncommutative algebra can be generalized to the setting of structured ring spectra.

The remainder of this chapter is devoted to studying the deformation theory of $E_k$-rings. In §7.3, we will introduce a general formalism describing the relative cotangent complex $L_{B/A}$ of a morphism $\phi : A \to B$ in a presentable $\infty$-category $\mathcal{C}$. When $\mathcal{C}$ is the $\infty$-category of $E_\infty$-rings, then we can identify $L_{B/A}$ with an object of the $\infty$-category $\text{Mod}_B(\text{Sp})$ of $B$-module spectra. In §7.4, we will see that many questions about a map $\phi : A \to B$ of $E_\infty$-rings can be reduced to questions about $L_{B/A}$: that is, to problems in stable homotopy theory. In §7.5, we will apply this technology to obtain a classification of étale morphisms between structured ring spectra.

**Warning 7.0.0.1.** Let $R$ be an associative ring, and let $M$ and $N$ be right and left modules over $R$, respectively. Then we can regard $R$ as a discrete $E_1$-algebra in the $\infty$-category of spectra, and $M$ and $N$ as discrete module spectra over $R$. Consequently, we can compute the tensor product $M \otimes_R N$ either in the $\infty$-category of spectra or in the ordinary category of abelian groups. Unless otherwise specified, the notation
\( M \otimes_R N \) will indicate the relative tensor product in the \( \infty \)-category of spectra. We will denote the ordinary algebraic tensor product by \( \text{Tor}_R^0(M, N) \). These are generally different from one another: for example, the spectrum \( M \otimes_R N \) need not be discrete. In fact, in \( \S 7.2 \) we will see that there are canonical isomorphisms \( \pi_i(M \otimes_R N) \simeq \text{Tor}_R^i(M, N) \) (Corollary 7.2.1.22). In particular, the algebraic tensor product \( \text{Tor}_R^0(M, N) \) can be realized as the 0th homotopy group of the spectrum \( M \otimes_R N \).

In cases where the groups \( \text{Tor}_i^R(M, N) \) vanish for \( i > 0 \) (for example, if either \( M \) or \( N \) is a projective module over \( R \)), we will generally not distinguish in notation between \( M \otimes_R N \) and \( \text{Tor}_R^0(M, N) \).

**Remark 7.0.0.2.** The theory of structured ring spectra plays an important role in modern stable homotopy theory. There is a vast literature on the subject, which we will not attempt to review here. We refer the readers to [51] for a foundational approach using the language of model categories, rather than the language of \( \infty \)-categories which we employ in this book.

### 7.1 Structured Ring Spectra

In this section, we introduce homotopy-theoretic analogues of some elementary notions from commutative and noncommutative algebra. Our starting point is the following:

**Definition 7.1.0.1.** Let \( 0 \leq k \leq \infty \), and let \( \text{Sp} \) denote the \( \infty \)-category of spectra (which we regard as endowed with the smash product monoidal structure of \( \S 4.8.2 \)). Let \( \mathbb{E}_k^\otimes \) denote the \( \infty \)-operad of little \( k \)-cubes (Definition 5.1.0.2). An \( \mathbb{E}_k \)-ring is an \( \mathbb{E}_k \)-algebra object of \( \text{Sp} \). We let \( \text{Alg}^{(k)} \) denote the \( \infty \)-category \( \text{Alg}_{\mathbb{E}_k}(\text{Sp}) \) of \( \mathbb{E}_k \)-rings.

In the special case \( k = \infty \), we will agree that \( \mathbb{E}_k^\otimes \) denotes the commutative \( \infty \)-operad \( \text{Comm}^\otimes = N(\text{Fin}_*) \) (see Corollary 5.1.1.5) and we let \( \text{CAlg} \) denote the \( \infty \)-category \( \text{CAlg}(\text{Sp}) = \text{Alg}_{\mathbb{E}_\infty}(\text{Sp}) \) of \( \mathbb{E}_\infty \)-rings.

**Remark 7.1.0.2.** The terminology of Definition 7.1.0.1 is somewhat nonstandard. What we call \( \mathbb{E}_k \)-rings are often called \( \mathbb{E}_k \)-ring spectra. In the special case \( k = \infty \), the term commutative ring spectrum is sometimes used, though some authors reserve this term for commutative algebra objects in the homotopy category \( \text{hSp} \) (that is, spectra which are equipped with a multiplication which is commutative and associative up to homotopy, rather than up to coherent homotopy). In the special case \( k = 1 \), many authors refer to \( \mathbb{E}_1 \)-rings as associative ring spectra or \( A_\infty \)-ring spectra.

**Remark 7.1.0.3.** Let \( R \) be an \( \mathbb{E}_k \)-ring for \( 0 \leq k \leq \infty \). We will say that \( R \) is discrete if its underlying spectrum is discrete: that is, if \( \pi_i R \simeq 0 \) for \( i \neq 0 \). The \( \infty \)-category of discrete \( \mathbb{E}_k \)-rings can be identified with the \( \infty \)-category of \( \mathbb{E}_k \)-algebra objects of \( \text{Sp}^\otimes \), which is equivalent to the nerve of the ordinary category of abelian groups. It follows that when \( k = 1 \), the \( \infty \)-category of discrete \( \mathbb{E}_1 \)-rings is equivalent to the nerve of the category of associative rings. Using Corollary 5.1.1.7, we see that the \( \infty \)-category of discrete \( \mathbb{E}_k \)-rings is equivalent to the nerve of the category of commutative rings whenever \( k \geq 2 \).

**Remark 7.1.0.4.** If \( R \) is an \( \mathbb{E}_k \)-ring, then we can view \( R \) as an \( \mathbb{E}_{k'} \)-ring for any \( k' \leq k \). More precisely, the sequence of maps

\[ \mathbb{E}_0^\otimes \to \mathbb{E}_1^\otimes \to \cdots \to \mathbb{E}_k^\otimes = \text{Comm}^\otimes \]

induces forgetful functors

\[ \text{CAlg} \to \cdots \to \text{Alg}^{(2)} \to \text{Alg}^{(1)} \to \text{Alg}^{(0)} \]

If \( R \in \text{Alg}^{(k)} \), we will generally abuse notation by identifying \( R \) with its image in \( \text{Alg}^{(k')} \) for \( k' \leq k \).

**Remark 7.1.0.5.** Using Remark 4.8.2.22, we can identify the \( \infty \)-category \( \text{Alg}_1^{(1)} \) of \( \mathbb{E}_1 \)-rings with the full subcategory of \( \text{Alg}(\text{Fun}(\text{Sp}, \text{Sp})) \) spanned by those monads \( T \) on \( \text{Sp} \) which preserve small colimits.

We will begin our study of \( \mathbb{E}_k \)-rings by considering the case \( k = 1 \). According to Example 5.1.0.7, we can identify the \( \infty \)-category \( \text{Alg}_1^{(1)} \) of \( \mathbb{E}_1 \)-rings with the \( \infty \)-category \( \text{Alg} = \text{Alg}(\text{Sp}) \). In other words, we can think of an \( \mathbb{E}_1 \)-ring as a spectrum \( A \) equipped with a multiplication \( A \otimes A \to A \), which is associative up
to coherent homotopy. The technology of Chapter 4 provides us with a robust theory of (left and right) modules over \( \mathbb{E}_1 \)-rings, which we study in §7.1.1.

For any \( \mathbb{E}_1 \)-ring \( A \), the \( \infty \)-category \( \text{LMod}_A = \text{LMod}_A(\text{Sp}) \) is stable and compactly generated. In §7.1.2 we will prove a converse to this statement (due to Schwede and Shipley): if \( \mathcal{C} \) is a presentable stable \( \infty \)-category which is generated by a single compact object \( 1 \in \mathcal{C} \), then we can describe \( \mathcal{C} \) as the \( \infty \)-category of left modules over the endomorphism object \( R = \text{End}_1(1) \) (see Theorem 7.1.2.1). Moreover, we show that promoting \( R \) to an \( \mathbb{E}_{k+1} \)-ring is equivalent to promoting \( \mathcal{C} \) to an \( \mathbb{E}_k \)-monoidal \( \infty \)-category (having \( 1 \) as unit object). In this case, it makes sense to consider \( \mathbb{E}_k \)-algebra objects of \( \mathcal{C} \), which we refer to as \( \mathbb{E}_k \)-algebras of \( \mathcal{C} \). In §7.1.3, we will study the theory of \( \mathbb{E}_k \)-algebras over an \( \mathbb{E}_{k+1} \)-ring \( R \), and prove a technical result (Theorem 7.1.3.1) which implies that many natural constructions are compatible with change of \( R \).

Using Theorem 4.1.4.4, we conclude that \( \text{Alg}^{(1)} \) is equivalent to the underlying \( \infty \)-category of strictly associative monoids in any sufficiently nice monoidal model category of spectra (see Example 4.1.4.6). If we are interested in studying algebras over a discrete \( \mathbb{E}_\infty \)-ring \( R \), then much more concrete models are available. In §7.1.4, we will show that the theory of \( \mathbb{E}_1 \)-algebras over \( R \) is equivalent to the theory of differential graded algebras (Proposition 7.1.4.6). When \( R \) contains the field \( \mathbb{Q} \) of rational numbers, there is a similar description of the \( \infty \)-category of \( \mathbb{E}_\infty \)-algebras over \( R \) (Proposition 7.1.4.11).

### 7.1.1 \( \mathbb{E}_1 \)-Rings and Their Modules

Let \( R \in \text{Alg}^{(1)} \) be an \( \mathbb{E}_1 \)-ring. In this section, we will introduce the theory of \( R \)-module spectra. This can be regarded as a generalization of homological algebra: if \( R \) is an ordinary ring (regarded as a discrete \( \mathbb{E}_1 \)-ring via Proposition 7.1.3.18), then the homotopy category of \( R \)-module spectra coincides with the classical derived category of \( R \) (Proposition 7.1.1.15); in particular, the theory of \( R \)-module spectra is a generalization of the usual theory of \( R \)-modules.

**Notation 7.1.1.1.** According to Example 5.1.0.7, there is a trivial Kan fibration of \( \infty \)-operads \( q : \mathbb{E}_1^\otimes \to \text{Ass}^\otimes \). We will fix a section of \( q \). For any symmetric monoidal \( \infty \)-category \( \mathcal{C} \), composition with this section induces an equivalence of \( \infty \)-categories \( \theta : \text{Alg}_{\mathbb{E}_1}(\mathcal{C}) \to \text{Alg}(\mathcal{C}) \). We will generally abuse notation by identifying an \( \mathbb{E}_1 \)-algebra object \( A \in \text{Alg}_{\mathbb{E}_1}(\mathcal{C}) \) with its image in \( \text{Alg}(\mathcal{C}) \). In particular, we will denote the \( \infty \)-categories \( \text{LMod}_{\mathbb{E}_1}(\mathcal{C}) \) and \( \text{RMod}_{\mathbb{E}_1}(\mathcal{C}) \) defined in §4.2.1 by \( \text{LMod}_A(\mathcal{C}) \) and \( \text{RMod}_A(\mathcal{C}) \), respectively.

If \( A \) is an \( \mathbb{E}_\infty \)-ring, then we let \( \text{Mod}_A \) denote the \( \infty \)-category \( \text{Mod}_{\mathbb{E}_1}(\mathcal{C}) \), so that we have canonical equivalences

\[
\text{LMod}_A \leftrightarrow \text{Mod}_A \leftrightarrow \text{RMod}_A
\]

(see Proposition 4.5.1.4).

**Definition 7.1.1.2.** Let \( R \) be an \( \mathbb{E}_1 \)-ring. We let \( \text{LMod}_R \) denote the \( \infty \)-category \( \text{LMod}_R(\text{Sp}) \). We will refer to \( \text{LMod}_R \) as the \( \infty \)-category of left \( R \)-module spectra. Similarly, we let \( \text{RMod}_R \) denote the \( \infty \)-category \( \text{RMod}_R(\text{Sp}) \) of right \( R \)-module spectra.

**Remark 7.1.1.3.** If \( R \) is an \( \mathbb{E}_1 \)-ring, we will often refer to (left or right) \( R \)-module spectra simply as (left or right) \( R \)-modules.

For the sake of definiteness, we will confine our attention to the study of left module spectra throughout this section; the theory of right module spectra can be treated in an entirely parallel way.

Our first goal is to prove that the \( \infty \)-category of modules over an \( \mathbb{E}_1 \)-ring is stable. This is a consequence of the following more general assertion:

**Proposition 7.1.1.4.** Let \( \mathcal{C} \) be an \( \infty \)-category equipped with a monoidal structure and a left action on an \( \infty \)-category \( \mathcal{M} \). Assume that \( \mathcal{M} \) is a stable \( \infty \)-category, and let \( R \in \text{Alg}(\mathcal{C}) \) be such that the functor \( \mathcal{M} \to \mathcal{C} \otimes \mathcal{M} \) is exact. Then \( \text{LMod}_R(\mathcal{M}) \) is a stable \( \infty \)-category. Moreover, if \( \mathcal{N} \) is an arbitrary stable \( \infty \)-category, then a functor \( \mathcal{N} \to \text{LMod}_R(\mathcal{M}) \) is exact if and only if the composite functor \( \mathcal{N} \to \text{LMod}_R(\mathcal{M}) \to \mathcal{M} \) is exact. In particular, the forgetful functor \( \text{LMod}_R(\mathcal{M}) \to \mathcal{M} \) is exact.
We will say that \( M \) preserves colimits separately in each variable, we conclude that \( Y \) and is stable under colimits and extensions. Let \( \pi_n R \) denote the \( n \)th homotopy group of the underlying spectrum. We observe that \( \pi_n R \) can be identified with the set \( \pi_0 \text{Map}_{\text{Sp}}(S[n], R) \), where \( S \) denotes the sphere spectrum. Since \( S \) is the identity for the smash product, there is a canonical equivalence \( S \otimes S \simeq S \); using the fact that \( \otimes \) is exact in each variable, we deduce the existence of equivalences \( S[n] \otimes S[m] \simeq S[n+m] \) for all \( n, m \in \mathbb{Z} \). The multiplication map

\[
\text{Map}_\text{Sp}(S[n], R) \times \text{Map}_\text{Sp}(S[m], R) \rightarrow \text{Map}_\text{Sp}(S[n] \otimes S[m], R) \rightarrow \text{Map}_\text{Sp}(S[n+m], R)
\]
determines a bilinear map \( \pi_n R \times \pi_m R \rightarrow \pi_{n+m} R \). It is not difficult to see that these maps endow \( \pi_* R = \bigoplus \pi_n R \) with the structure of a graded associative ring, which depends functorially on \( R \). In particular, \( \pi_0 R \) is an ordinary associative ring, and each \( \pi_n R \) has the structure of a \( \pi_0 R \)-bimodule.

**Remark 7.1.1.6.** If \( R \) admits the structure of an \( \mathbb{E}_k \)-ring for \( k \geq 2 \), we can say a bit more. In this case, the multiplication on \( R \) is commutative (up to homotopy). It follows that the multiplication on \( \pi_* R \) is graded commutative. That is, for \( x \in \pi_n R \) and \( y \in \pi_m R \), we have \( xy = (-1)^{nm}yx \). Here the sign results from the fact that the composition

\[
S[n+m] \simeq S[n] \otimes S[m] \simeq S[m] \otimes S[n] \simeq S[n+m]
\]
is given by the sign \((-1)^{nm}\). In particular, the homotopy group \( \pi_0 R \) is equipped with the structure of a commutative ring, and every other homotopy group \( \pi_n R \) has the structure of a module over \( \pi_0 R \).

We will need the following basic result:

**Lemma 7.1.1.7.** The \( \infty \)-category \( \text{Sp} \) determined by the class of connective objects is compatible with the smash product symmetric monoidal structure (in the sense of Example 2.2.1.3). In other words, the full subcategory \( \text{Sp}^{\text{cn}} \subseteq \text{Sp} \) spanned by the connective objects is closed under smash products and contains the unit object. Consequently, the monoidal structure on \( \text{Sp} \) determines a monoidal structure on \( \text{Sp}^{\text{cn}} \).

**Proof.** The \( \infty \)-category \( \text{Sp}^{\text{cn}} \) is the smallest full subcategory of \( \text{Sp} \) which contains the sphere spectrum \( S \in \text{Sp} \) and is stable under colimits and extensions. Let \( \mathcal{C} \) be the full subcategory of \( \text{Sp} \) spanned by those spectra \( X \) such that, for all \( Y \in \text{Sp}^{\text{cn}} \), \( X \otimes Y \) is connective. We wish to prove that \( \text{Sp}^{\text{cn}} \subseteq \mathcal{C} \). Since the smash product preserves colimits separately in each variable, we conclude that \( \mathcal{C} \) is closed under colimits and extensions in \( \text{Sp} \). It will therefore suffice to prove that \( S \in \mathcal{C} \). This is clear, since \( S \) is the unit object of \( \text{Sp} \).

Recall that a spectrum \( X \) is said to be *connective* if \( \pi_n X \simeq 0 \) for \( n < 0 \). We will say that an \( \mathbb{E}_k \)-ring \( R \) is *connective* if its underlying spectrum is connective. We let \( \text{Alg}^{(k) \text{cn}} \) denote the full subcategory of \( \text{Alg}^{(k)} \) spanned by the connective \( \mathbb{E}_k \)-rings. We can equivalently define \( \text{Alg}^{(k) \text{cn}} \) to be the \( \infty \)-category \( \text{Alg}_{\mathbb{E}_k}(\text{Sp}^{\text{cn}}) \), where \( \text{Sp}^{\text{cn}} \) denotes the full subcategory of \( \text{Sp} \) spanned by the connective spectra (the full subcategory \( \text{Sp}^{\text{cn}} \subseteq \text{Sp} \) inherits a symmetric monoidal structure in view of Proposition 2.2.1.1 and Lemma 7.1.1.7). In the special case \( k = \infty \), we will denote this \( \infty \)-category \( \text{CAlg}_{\mathbb{E}_k}(\text{Sp}^{\text{cn}}) \) by \( \text{CAlg}^{\text{cn}} \).

Let \( M \) be a left \( R \)-module spectrum for some \( \mathbb{E}_1 \)-ring \( R \). We will generally abuse notation by identifying \( M \) with its image in \( \text{Sp} \). In particular, we define the homotopy groups \( \{ \pi_n M \}_{n \in \mathbb{Z}} \) of \( M \) to be the homotopy groups of the underlying spectrum. The action map \( R \otimes M \rightarrow M \) induces bilinear maps \( \pi_n R \times \pi_m M \rightarrow \pi_{n+m} M \), which endow the sum \( \pi_* M = \bigoplus_{n \in \mathbb{Z}} \pi_n M \) with the structure of a graded left module over \( \pi_* R \). We will say that \( M \) is *connective* if its underlying spectrum is connective; that is, if \( \pi_n M \simeq 0 \) for \( n < 0 \).
Remark 7.1.1.8. When restricted to connective $\mathbb{E}_k$-rings, the functor $\Omega^\infty$ detects equivalences: if $f : A \to B$ is a morphism in $\text{Alg}^{(k),c_n}$ such that $\Omega^\infty(f)$ is an equivalence, then $f$ is an equivalence. We observe that the functor $\Omega^\infty : \text{Alg}^{(k),c_n} \to \mathcal{S}$ is a composition of a pair of functors $\text{Alg}_{\mathbb{E}_k}(\text{Sp}^{c_n}) \to \text{Sp}^{c_n} \to \mathcal{S}$, both of which preserve sifted colimits (Corollaries 3.2.3.2 and 1.4.3.9) and admit left adjoints. It follows from Theorem 4.7.4.5 that $\text{Alg}^{(k),c_n}$ can be identified with the $\infty$-category of modules over a suitable monad on $\mathcal{S}$. In other words, we can view connective $\mathbb{E}_k$-rings as spaces equipped with some additional structures. Roughly speaking, these additional structures consist of an addition and multiplication which satisfy the axioms for a ring (commutative if $k \geq 2$), up to coherent homotopy.

The functor $\Omega^\infty : \text{Alg}^{(k)} \to \mathcal{S}$ is not conservative: a map of $\mathbb{E}_k$-rings $f : A \to B$ which induces a homotopy equivalence of underlying spaces need not be an equivalence in $\text{Alg}^{(k)}$. We observe that $f$ is an equivalence of $\mathbb{E}_k$-rings if and only if it is an equivalence of spectra; that is, if and only if $\pi_n(f) : \pi_n A \to \pi_n B$ is an isomorphism of abelian groups for all $n \in \mathbb{Z}$. However, $\Omega^\infty(f)$ is a homotopy equivalence of spaces provided only that $\pi_n(f)$ is an isomorphism for $n \geq 0$; this is generally a weaker condition.

Remark 7.1.1.9. Roughly speaking, if we think of an $\mathbb{E}_1$-ring $R$ as a space equipped with the structure of an associative ring up to coherent homotopy, then a left $R$-module can be thought of as another space which has an addition and a left action of $R$, up to coherent homotopy in the same sense. This intuition is really only appropriate in the case where $R$ and $M$ are connective, since the homotopy groups in negative degree have no simple interpretation in terms of underlying spaces.

If $R$ is a connective $\mathbb{E}_1$-ring, the formation of homotopy groups of a left $R$-module $M$ can be interpreted in terms of an appropriate $t$-structure on $\text{LMod}_R$.

Notation 7.1.1.10. If $R$ is an $\mathbb{E}_1$-ring, we let $\text{LMod}^0_R$ be the full subcategory of $\text{LMod}_R$ spanned by those left $R$-modules $M$ for which $\pi_nM \simeq 0$ for $n < 0$, and $\text{LMod}^{\leq 0}_R$ the full subcategory of $\text{LMod}_R$ spanned by those $R$-modules $M$ for which $\pi_nM \simeq 0$ for $n > 0$.

Notation 7.1.1.11. Let $R$ be an $\mathbb{E}_1$-ring, and let $M$ and $N$ be left $R$-modules. We let $\text{Ext}_R^i(M, N)$ denote the abelian group $\pi_0 \text{Map}_{\text{LMod}_R}(M, N[i])$.

Remark 7.1.1.12. Suppose that $R$ is an associative ring, regarded as a discrete $\mathbb{E}_1$-ring, and let $M$ and $N$ be discrete left $R$-modules. Then the abelian groups $\text{Ext}_R^i(M, N)$ of Notation 7.1.1.11 can be identified with the usual Yoneda Ext-groups, computed in the abelian category of (discrete) left $R$-modules. This is a consequence of Proposition 7.1.1.15, proven below.

Proposition 7.1.1.13. Let $R$ be a connective $\mathbb{E}_1$-ring. Then:

1. The full subcategory $\text{LMod}^0_R \subseteq \text{LMod}_R$ is the smallest full subcategory which contains $R$ (regarded as an $R$-module in the natural way; see Example 4.2.1.17) and is stable under small colimits.

2. The subcategories $\text{LMod}_{R}^{0}, \text{LMod}_{R}^{\leq 0}$ determine an accessible $t$-structure on $\text{LMod}_R$ (see §1.2.1).

3. The $t$-structure described in (2) is both left and right complete, and the functor $\pi_0$ determines an equivalence of the heart $\text{LMod}^0_R$ with the (nerve of the) ordinary category of (discrete) $\pi_0R$-modules.

4. The subcategories $\text{LMod}^{0}_R, \text{LMod}^{\leq 0}_R \subseteq \text{LMod}_R$ are stable under small products and small filtered colimits.

Proof. According to Proposition 1.4.4.11, there exists an accessible $t$-structure $(\text{LMod}_R', \text{LMod}_R'')$ with the following properties:

(a) An object $M \in \text{LMod}_R$ belongs to $\text{LMod}_R''$ if and only if $\text{Ext}_R^i(R, M) \simeq 0$ for $i < 0$.

(b) The $\infty$-category $\text{LMod}_R'$ is the smallest full subcategory of $\text{LMod}_R$ which contains the object $R$ and is stable under extensions and small colimits.
Corollary 4.2.4.8 implies that \( R \) (regarded as an object of \( \text{LMod}_R \)) corepresents the composition \( \text{LMod}_R \rightarrow \text{Sp} \overset{L_{\Sigma}^\infty}{\rightarrow} S \). It follows that \( \text{LMod}_R^{\geq 0} = \text{LMod}_{R}^{\geq 0} \). Because the forgetful functor \( \text{LMod}_R \rightarrow \text{Sp} \) preserves small colimits (Corollary 4.2.3.5), we conclude that \( \text{LMod}_R^{\geq 0} \) is stable under extensions and small colimits. Since \( R \) is connective, \( R \in \text{LMod}_R^{\geq 0} \), so that \( \text{LMod}_R^{\geq 0} \subseteq \text{LMod}_R^{\geq 0} \). Let \( \mathcal{C} \) be the smallest full subcategory of \( \text{LMod}_R \) which contains \( R \) and is stable under small colimits, so that \( \mathcal{C} \subseteq \text{LMod}_R^{\geq 0} \). We will complete the proof of (1) and (2) by showing that \( \mathcal{C} = \text{LMod}_R^{\geq 0} \).

Let \( M \in \text{LMod}_R^{\geq 0} \). We will construct a diagram

\[
M(0) \rightarrow M(1) \rightarrow M(2) \rightarrow \ldots
\]

in \( (\text{LMod}_R)_M \) with the following properties:

(i) Let \( i \geq 0 \), and let \( K(i) \) be a fiber of the map \( M(i) \rightarrow M \). Then \( \pi_j K(i) \simeq 0 \) for \( j < i \).

(ii) The \( R \)-module \( M(0) \) is a coproduct of copies of \( R \).

(iii) For \( i \geq 0 \), there is a pushout diagram

\[
\begin{array}{ccc}
F[i] & \rightarrow & 0 \\
\downarrow & & \downarrow \\
M(i) & \rightarrow & M(i+1),
\end{array}
\]

where \( F \) is a coproduct of copies of \( R \).

We begin by choosing \( M(0) \) to be any coproduct of copies of \( R \) equipped with a map \( M(0) \rightarrow M \) which induces a surjection \( \pi_0 M(0) \rightarrow \pi_0 M \); for example, we can take \( M(0) \) to be a coproduct of copies of \( R \) indexed by \( \pi_0 M \). Let us now suppose that the map \( f : M(i) \rightarrow M \) has been constructed, with \( K(i) = \text{fib}(f) \) such that \( \pi_j K(i) \simeq 0 \) for \( j < i \). We now choose \( F \) to be a coproduct of copies of \( R \) and a map \( g : F[i] \rightarrow K(i) \) which induces a surjection \( \pi_0 F \rightarrow \pi_0 K(i) \). Let \( h \) denote the composite map \( F[i] \rightarrow K(i) \rightarrow M(i) \), and let \( M(i+1) = \text{cofib}(h) \). The canonical nullhomotopy of \( K(i) \rightarrow M(i) \rightarrow M \) induces a factorization

\[
M(i) \rightarrow M(i+1) \xrightarrow{\ell} M
\]

of \( f \). We observe that there is a canonical equivalence \( \text{fib}(f') \simeq \text{cofib}(g) \), so that \( \pi_j \text{fib}(f') \simeq 0 \) for \( j \leq i \).

Let \( M(\infty) \) be the colimit of the sequence \( \{M(i)\} \), and let \( K \) be the fiber of the canonical map \( M(\infty) \rightarrow M \). Then \( K \) can be identified with a colimit of the sequence \( \{K(i)\}_{i \geq 0} \). Since the formation of homotopy groups is preserves filtered colimits, we conclude that \( \pi_j K \simeq \text{colim} \pi_j K(i) \simeq 0 \). Thus \( M(\infty) \simeq M \), so that \( M \in \mathcal{C} \) as desired.

Assertion (4) follows from the corresponding result for \( \text{Sp} \), since the forgetful functor \( \text{LMod}_R \rightarrow \text{Sp} \) preserves all limits and colimits (Corollaries 4.2.3.3 and 4.2.3.5). Since \( \text{LMod}_R \rightarrow \text{Sp} \) is a conservative functor, an \( R \)-module \( M \) is zero if and only if \( \pi_n M \) is zero for all \( n \in \mathbb{Z} \). It follows from Proposition 1.2.1.19 that \( \text{LMod}_R \) is both right and left complete.

Let \( F \) be the functor from \( \text{LMod}_R^{\geq 0} \) to the (nerve of the) ordinary category of left \( \pi_0 R \)-modules, given by \( M \mapsto \pi_0 M \). It is easy to see that \( F \) preserves colimits, and that the restriction of \( F \) to \( \text{LMod}_R^{\geq 0} \) is an exact functor. We wish to prove that \( F_0 = F|_{\text{LMod}_R^{\geq 0}} \) is an equivalence. We first show that the restriction of \( F_0 \) is fully faithful. Fix \( N \in \text{LMod}_R^{\geq 0} \), and let \( \mathcal{D} \) be the full subcategory of \( \text{LMod}_R^{\geq 0} \) spanned by those objects \( M \) for which the map \( \pi_0 \text{Map}_{\text{LMod}_R}(M,N) \rightarrow \text{Hom}(\tau_{\leq 0} M,F(N)) \) is bijective, where the right hand side indicates the group of \( \pi_0 R \)-module homomorphisms. It is easy to see that \( \mathcal{D} \) is stable under colimits and contains \( R \). The first part of the proof shows that \( \mathcal{D} = \text{LMod}_R^{\geq 0} \). In particular, \( F_0 \) is fully faithful.

It remains to show that \( F_0 \) is essentially surjective. Since \( F_0 \) is fully faithful and exact, the essential image of \( F_0 \) is closed under the formation of cofibers. It will therefore suffice to show that every free left \( \pi_0 R \)-module belongs to the essential image of \( F_0 \). Since \( F_0 \) preserves coproducts, it will suffice to show that \( \pi_0 R \) itself belongs to the essential image of \( F_0 \). We now conclude by observing that \( F_0(\tau_{\leq 0} R) \simeq \pi_0 R \). \( \square \)
**Warning 7.1.1.14.** Let $R$ be an associative ring, which we can identify with a discrete $E_1$-ring (Proposition 7.1.3.18). The theory of $R$-module spectra (Definition 7.1.1.2) does not agree with the usual theory of $R$-modules. Instead, Proposition 7.1.1.13 allows us to identify the usual category of $R$-modules with the ∞-category of discrete $R$-module spectra.

Let $R$ be a connective $E_1$-ring, let $A$ be the abelian category of left modules over the (ordinary) ring $\pi_0 R$. Then $A$ has enough projective objects, so we can consider the derived ∞-category $\mathcal{D}^-(A)$ described in §1.3.2. Part (3) of Proposition 7.1.1.13 determines an equivalence $N(A) \simeq \mathbb{L}_{\mathcal{D}} R$. Using Proposition 1.3.3.12, we deduce the existence of an (essentially unique) right t-exact functor $\theta : \mathcal{D}^-(A) \to \mathbb{L}_{\mathcal{D}} R$.

**Proposition 7.1.1.15.** Let $R$ be a connective $E_1$-ring, and let $\theta : \mathcal{D}^-(A) \to \mathbb{L}_{\mathcal{D}} R$ be the functor constructed above. The following conditions are equivalent:

1. The $E_1$-ring $R$ is discrete. That is, $\pi_i R \simeq 0$ for $i > 0$.
2. The functor $\theta$ is fully faithful, and induces an equivalence of $\mathcal{D}^-(A)$ with the ∞-category of right bounded objects of $\mathbb{L}_{\mathcal{D}} R$.

**Proof.** Let $P \in A$ be the projective object corresponding to the free left $\pi_0 R$-module on one generator. Then, for $M \in \mathcal{D}^-(A)$, we have a canonical isomorphism $\text{Ext}_R^0(\theta(P), M) \simeq \pi_0 M$. If (2) is satisfied, then we deduce the existence of a canonical isomorphisms

$$\text{Ext}_R^0(\theta(P), M) \simeq \pi_0 M \simeq \text{Ext}^0(R, M)$$

for $M \in \mathbb{L}_{\mathcal{D}} R_0$. Thus $\theta(P)$ and $R$ are isomorphic in the homotopy category $\mathbb{hL}_{\mathcal{D}} R$. Since $\theta(P)$ is discrete, we conclude that $R$ is discrete, which proves (1).

For the converse, let us suppose that $R$ is discrete. Let us regard (the nerve of) $A$ as a full subcategory of both $\mathcal{D}^-(A)$ and $\mathbb{L}_{\mathcal{D}} R$. For $M, N \in A$, let $\text{Ext}_A^i(M, N)$ denote the abelian group $\pi_i \text{Map}_{\mathcal{D}^-(A)}(M, N[i])$ (in other words, $\text{Ext}_A^i(M, N)$ is the classical Yoneda Ext-group computed in the abelian category $A$). We claim that the canonical map $\text{Ext}_A^i(M, N) \to \text{Ext}_R^i(M, N)$ is an isomorphism. For $i < 0$, both sides vanish. The proof in general goes by induction on $i$, the case $i = 0$ being trivial. For $i > 0$, we choose an exact sequence

$$0 \to K \to P \to M \to 0$$

in $A$, where $P$ is a free $\pi_0 R$-module. We have a commutative diagram of abelian groups with exact rows

$$\begin{array}{cccccc}
\text{Ext}_A^{i-1}(P, N) & \longrightarrow & \text{Ext}_A^{i-1}(K, N) & \longrightarrow & \text{Ext}_A^i(M, N) & \longrightarrow & \text{Ext}_A^i(P, N) \\
\psi_1 \downarrow & & \psi_2 \downarrow & & \psi_3 & & \\
\text{Ext}_R^{i-1}(P, N) & \longrightarrow & \text{Ext}_R^{i-1}(K, N) & \longrightarrow & \text{Ext}_R^i(M, N) & \longrightarrow & \text{Ext}_R^i(P, N).
\end{array}$$

We wish to show that $\psi_3$ is an isomorphism. Since $\psi_1$ and $\psi_2$ are bijective by the inductive hypothesis, it will suffice to show that $\text{Ext}_A^i(P, N) \simeq 0 \simeq \text{Ext}_R^i(P, N)$. The first equivalence follows from the fact that $P$ is a projective object of $A$. For the second, we observe that as an object of $\mathbb{L}_{\mathcal{D}} R$, $P$ coincides with a coproduct of copies of $R$ (in virtue of assumption (1)). Consequently, $\text{Ext}_R^i(P, N)$ can be identified with a product of copies of $\pi_i N$, which vanishes since $i > 0$ and $N \in \mathbb{L}_{\mathcal{D}} R_0$.

Now suppose that $M \in A$, and consider the full subcategory $\mathcal{C} \subseteq \mathcal{D}^-(A)$ spanned by those objects $N$ for which the canonical map $\text{Ext}_A^i(M, N) \to \text{Ext}_R^i(\theta(M), \theta(N))$ is an isomorphism for all $i \in \mathbb{Z}$. Applying the five lemma to the relevant long exact sequences, we conclude that $\mathcal{C}$ is stable under extensions in $\mathcal{D}^-(A)$. The above argument shows that $\mathcal{C}$ contains the heart of $\mathcal{D}^-(A)$; it therefore contains the full subcategory $\mathbb{D}_R^b(A)$ of bounded object of $\mathcal{D}^-(A)$.

Now let $\mathcal{C}' \subseteq \mathcal{D}^-(A)$ spanned by those objects $M$ having the property that for every $N \in \mathbb{D}_R^b(A)$, the canonical map $\text{Ext}_A^i(\mathcal{D}^-(A), M, N) \to \text{Ext}_R^i(\theta(M), \theta(N))$ is an isomorphism for $i \in \mathbb{Z}$. Repeating the above argument, we conclude that $\mathbb{D}_R^b(A) \subseteq \mathcal{C}'$. In particular, the restriction $\theta | \mathbb{D}_R^b(A)$ is fully faithful.
We claim that the essential image of $\theta|\mathcal{D}^b(A)$ consists of precisely the t-bounded objects of $\mathsf{LMod}_R$. Let $M \in \mathsf{LMod}_R$ be a t-bounded object. We wish to prove that $M$ belongs to the essential image of $\theta$. Without loss of generality, we may suppose that $M \in \mathsf{LMod}^{>0}_R$. Since $M$ is t-bounded, we have also $M \in \mathsf{LMod}^{\leq n}_R$ for some $n \geq 0$. We now work by induction on $n$. If $n = 0$, then $M$ belongs to the heart of $\mathsf{LMod}_R$ and the result is obvious. If $n > 0$, then we have a fiber sequence
\[ \tau_{\geq n} M \to M \to \tau_{\leq n-1} M. \]
Since $\theta$ is exact and fully faithful, it will suffice to show that $\tau_{\geq n} M[-n]$ and $\tau_{\leq n-1} M$ belong to the essential image of $\theta$, which follows from the inductive hypothesis.

The preceding argument shows that $\theta$ induces an equivalence $\mathcal{D}^b(A) \to \mathsf{LMod}_R^b$ between the full subcategories of bounded objects. We now conclude by observing that both $\mathcal{D}^-(A)$ and $\mathsf{LMod}_R$ are left complete.

**Remark 7.1.1.16.** Let $R$ and $A$ be as in Proposition 7.1.1.15, and assume that $R$ is discrete. Let $\mathcal{D}(A)$ be the unbounded derived $\infty$-category of $A$ (Definition 1.3.5.8), so that Proposition 1.3.5.24 allows us to identify $\mathcal{D}^-(A)$ with the full subcategory of $\mathcal{D}(A)$ spanned by the right bounded objects. Since $\mathcal{D}(A)$ and $\mathsf{LMod}_R$ are both right complete (Propositions 1.3.5.21 and 7.1.1.13), the fully faithful embedding $\mathcal{D}(A)^- \to \mathsf{LMod}_R$ induces an equivalence of $\infty$-categories $\mathcal{D}(A) \simeq \mathsf{LMod}_R$. In other words, the $\infty$-category of left $R$-module spectra can be identified with the derived $\infty$-category of the abelian category of (discrete) $R$-modules.

### 7.1.2 Recognition Principles

Let $R$ be a commutative ring and let $A$ denote the abelian category of (discrete) $R$-modules. We will regard $R$ as a discrete $E_\infty$-ring, and let $\mathsf{Mod}_R$ denote the $\infty$-category of $R$-module spectra as in Notation 7.1.1.1. According to Remark 7.1.1.16, we can identify $\mathsf{Mod}_R$ with the derived $\infty$-category $\mathcal{D}(A)$ of chain complexes of $R$-modules. Since $R$ is commutative, we can regard $\mathsf{Mod}_R$ as a symmetric monoidal $\infty$-category. In this section, we will show that the symmetric monoidal structure on $\mathsf{Mod}_R$ is determined by the symmetric monoidal structure on the ordinary category $\mathsf{Ch}(A)$ of chain complexes with values in $A$.

We begin with a much more general question. Given a stable $\infty$-category $\mathcal{C}$ (such as the derived $\infty$-category $\mathcal{D}(A)$ of an abelian category $A$), under what circumstances can $\mathcal{C}$ be realized as the $\infty$-category $\mathsf{RMod}_R$ of right modules over an $E_1$-ring $R$? This question is addressed by the following result of Schwede and Shipley:

**Theorem 7.1.2.1.** ([Schwede-Shipley [128]]) Let $\mathcal{C}$ be a stable $\infty$-category. Then $\mathcal{C}$ is equivalent to $\mathsf{RMod}_R$, for some $E_1$-ring $R$, if and only if $\mathcal{C}$ is presentable and there exists a compact object $C \in \mathcal{C}$ which generates $\mathcal{C}$ in the following sense: if $D \in \mathcal{C}$ is an object having the property that $\text{Ext}^n_{\mathcal{C}}(C, D) \simeq 0$ for all $n \in \mathbb{Z}$, then $D \simeq 0$.

**Proof.** Suppose first that $\mathcal{C} \simeq \mathsf{RMod}_R$, and let $C = R$ (regarded as a left module over itself). Then $\mathcal{C}$ is presentable, $C$ is a compact object of $\mathcal{C}$, and $\text{Ext}^n_{\mathcal{C}}(C, D) \simeq \pi_{-n} D$ for every object $D \in \mathcal{C}$. It follows that $D \simeq 0$ if and only if $\text{Ext}^n_{\mathcal{C}}(C, D) \simeq 0$ for all integers $n$, so that $C$ generates $\mathcal{C}$.

Conversely, suppose that $\mathcal{C}$ is presentable and let $C \in \mathcal{C}$ be a compact generator. Let $\mathcal{Pr}^L$ denote the symmetric monoidal $\infty$-category of presentable $\infty$-categories, so that we can regard $\mathcal{C}$ as a right module over the $\infty$-category $\mathsf{Sp}$ (see Proposition 4.8.2.18). We will complete the proof by showing that the pair $(\mathcal{C}, C)$ lies in the image of the fully faithful embedding $\mathsf{Alg}(\mathsf{Sp}) \to \mathsf{Mod}_{\mathsf{Sp}}(\mathcal{Pr}^L)_{\mathsf{Sp}}$ of Proposition 4.8.5.8. Corollary T.5.5.2.9 guarantees that the functor $F : \mathsf{Sp} \to \mathcal{C}$ given by $X \mapsto X \otimes C$ admits a right adjoint $G$. According to Proposition 4.8.5.8, it will suffice to show the following:

(a) The functor $G$ preserves geometric realizations of simplicial objects.

(b) The functor $G$ is conservative.

(c) For every object $D \in \mathcal{C}$ and every spectrum $X \in \mathsf{Sp}$, the canonical map $\theta_X : X \otimes G(D) \to G(X \otimes D)$ is an equivalence of spectra.
To prove (a), it suffices to show that $G$ preserves all small colimits. Since $G$ is exact, this is equivalent to the requirement that $G$ preserves small filtered colimits, which follows from our assumption that $C$ is compact. To prove (b), suppose we are given a map $\alpha : D \to D'$ such that $G(\alpha)$ is an equivalence. Let $D''$ be the cofiber of $\alpha$. Since $G$ is exact, we deduce that $G(D'') \simeq 0$, so that $\pi_n G(D'') \simeq \Ext_{\Sigma}^n(C, D'')$ vanishes for every integer $n$. Our assumption that $C$ describes the argument in the case where $C$ is also enriched over $\text{Sp}$, so that there exists a morphism object $\text{Mor}_{\text{Sp}}(S[n], X, X)$ can be lifted to a final object of the monoidal $\infty$-category $X \subseteq \text{Sp}$ is stable under small colimits. To prove that $X = \text{Sp}$, it suffices to show that $\pi_n = 0$ for every integer $n$, where $S$ denotes the sphere spectrum. Since the functor $G$ is exact, we can reduce to the case $n = 0$, where the result is obvious.

**Remark 7.1.2.2.** Let $\mathcal{C}$ be a stable $\infty$-category, and let $X \in \mathcal{C}$ be an object. Then it is possible to extract from $\mathcal{C}$ an $E_1$-ring spectrum $\text{End}_{\mathcal{C}}(X)$ with the property that $\pi_n \text{End}_{\mathcal{C}}(X) \simeq \Ext_{\Sigma}^n(X, X)$ for all $n \in \mathbb{Z}$, and the ring structure on $\pi_n \text{End}_{\mathcal{C}}(X)$ is given by composition in the triangulated category $h \mathcal{C}$. We will describe the argument in the case where $\mathcal{C}$ is presentable (the general case can be reduced to this case by first replacing $\mathcal{C}$ by a small subcategory which contains $X$, and then enlarging $\mathcal{C}$ by formally adjoining filtered colimits). According to Remark 4.8.2.20, the $\infty$-category $\mathcal{C}$ is naturally left-tensored over $\text{Sp}$. Proposition 4.2.1.33 implies that $\mathcal{C}$ is also enriched over $\text{Sp}$, so that there exists a morphism object $\text{Mor}_{\mathcal{C}}(X, X)$. The object $\text{End}_{\mathcal{C}}(X) = \text{Mor}_{\mathcal{C}}(X, X)$ can be lifted to a final object of the monoidal $\infty$-category $\mathcal{C}^\ast [X]$, and can therefore be lifted to $\text{Alg}(\text{Sp}) \simeq \text{Alg}_{\mathcal{C}}(\text{Sp})$. The identification of the homotopy groups of $\text{End}_{\mathcal{C}}(X)$ follows from the homotopy equivalence $\text{Map}_{\text{Sp}}(S[n], \text{End}_{\mathcal{C}}(X)) \simeq \text{Map}_{\mathcal{C}}(S[n] \otimes X, X)$.

**Remark 7.1.2.3.** Let $\mathcal{C}$ be a presentable stable $\infty$-category containing an object $C$. The $E_1$-ring $R$ appearing in the proof of Theorem 7.1.2.1 can be identified with the endomorphism algebra $\text{End}_{\mathcal{C}}(C)$ described in Remark 7.1.2.2.

In the situation of Theorem 7.1.2.1, the $E_1$-ring $R$ is determined up to equivalence by the pair $(\mathcal{C}, C)$, but not by the $\infty$-category $\mathcal{C}$ alone. As in classical Morita theory, an equivalence between module categories $R \text{Mod}_{\mathcal{C}}$ and $R \text{Mod}_{\mathcal{C}}'$ need not result from an equivalence between $R$ and $R'$. However, every equivalence between $R \text{Mod}_{\mathcal{C}}$ and $R \text{Mod}_{\mathcal{C}'}$ is obtained by tensor product with a suitable $R$-$R'$-bimodule spectrum. In fact, we have the following more general result:

**Proposition 7.1.2.4.** Let $R$ and $R'$ be $E_1$-rings, and let $\text{Fun}^L(\text{RMod}_R, \text{RMod}_{R'})$ be the $\infty$-category of functors from $\text{RMod}_R$ to $\text{RMod}_{R'}$ which preserve small colimits. Then the relative tensor product functor $\otimes_R : \text{RMod}_R \times_{R} \text{BMod}_{R'}(\text{Sp}) \to \text{RMod}_{R'}$ induces an equivalence of categories $\text{Fun}^L(\text{RMod}_R, \text{RMod}_{R'}) \to \text{Fun}^L(\text{RMod}_R, \text{RMod}_{R'})$.

**Proof.** Combine Proposition 4.8.2.18, Theorem 4.8.4.1, and Theorem 4.3.2.7.

If we wish to recover the $E_1$-ring from the $\infty$-category $\text{RMod}_{R}$ of right $R$-modules, we should consider not only $\text{RMod}_R$ but also the distinguished object $R$ (regarded as a right module over itself), whose endomorphism algebra can be identified with $R$. More generally, for any $k \geq 1$, we can recover an $E_k$-ring $R$ from the $\infty$-category of right $R$-modules, regarded as an $E_{k-1}$-monoidal $\infty$-category. Before stating the precise result, we need to introduce a bit of terminology.

**Notation 7.1.2.5.** Fix a section $s$ of the trivial Kan fibration $E_1^\infty \to \text{Ass}^\infty$ of Example 5.1.0.7, so that composition with $s$ determines a map of $\infty$-operads $\mathcal{R}M^\infty \to E_1^\infty$ and therefore a bifunctor of $\infty$-operads $\mathcal{R}M^\infty \times E_{k-1}^\infty \to E_k^\infty$ for each $k > 0$. If $\mathcal{C}$ is an $E_k$-monoidal $\infty$-category and $R \in \text{Alg}_{E_k}(\mathcal{C})$, then we let $\text{RMod}_R(\mathcal{C})$ denote the fiber product $\text{Alg}_{\mathcal{R}M/E_k}(\mathcal{C}) \times_{\text{Alg}_{\text{Ass}}/E_k} \{R\}$. If we assume that $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product on $\mathcal{C}$ preserves geometric realizations of simplicial objects, then the constructions of §4.8.3 show that $\text{RMod}_R(\mathcal{C})$ inherits the structure of an $E_{k-1}$-monoidal $\infty$-category.
Proposition 7.1.2.6. Let \( k \geq 1 \). The construction \( R \mapsto \text{RMod}_R^\otimes \) determines a fully faithful embedding from the \( \infty \)-category \( \text{Alg}_k^{(k)} \) of \( \mathbb{E}_k \)-rings to the \( \infty \)-category \( \text{Alg}_{\mathbb{E}_{k-1}}^{(k+1)}(\mathbb{P}_{k-1}) \) of \( \mathbb{E}_{k-1} \)-monoidal presentable \( \infty \)-categories. An \( \mathbb{E}_{k-1} \)-monoidal \( \infty \)-category \( \mathcal{C}^\otimes \to \mathbb{P}_{k-1}^\otimes \) belongs to the essential image of this embedding if and only if the following conditions are satisfied:

1. The \( \infty \)-category \( \mathcal{C} \) is stable and presentable, and if \( k > 1 \) then the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves small colimits separately in each variable.
2. The unit object \( 1 \in \mathcal{C} \) is compact.
3. The object \( 1 \) generates \( \mathcal{C} \) in the following sense: if \( C \in \mathcal{C} \) is an object such that \( \text{Ext}^i_\mathcal{C}(1, C) \simeq 0 \) for all integers \( i \), then \( C \simeq 0 \).

Proof. The full faithfulness follows from Corollary 5.1.2.6 and Proposition 4.8.2.18. The description of the essential image follows as in the proof of Theorem 7.1.2.1.

Proposition 7.1.2.6 is also valid (with the same proof) in the limiting case \( k = \infty \):

Proposition 7.1.2.7. The construction \( R \mapsto \text{Mod}_R^\otimes \) determines a fully faithful embedding from the \( \infty \)-category \( \text{CAlg}_k \) of \( \mathbb{E}_\infty \)-rings to the \( \infty \)-category \( \text{CAlg}_{\mathbb{E}_{k-1}}(\mathbb{P}_{k-1}) \) of presentable symmetric monoidal \( \infty \)-categories. A symmetric monoidal \( \infty \)-category \( \mathcal{C}^\otimes \) belongs to the essential image of this embedding if and only if the following conditions are satisfied:

1. The \( \infty \)-category \( \mathcal{C} \) is stable and presentable and the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves small colimits separately in each variable.
2. The unit object \( 1 \in \mathcal{C} \) is compact.
3. The object \( 1 \) generates \( \mathcal{C} \) in the following sense: if \( C \in \mathcal{C} \) is an object such that \( \text{Ext}^i_\mathcal{C}(1, C) \simeq 0 \) for all integers \( i \), then \( C \simeq 0 \).

Our next goal is to use Proposition 7.1.2.7 to address the question raised at the beginning of this section. Suppose that \( R \) is a commutative ring, and let \( \mathcal{A} \) be the category of chain complexes of \( R \)-modules. We will show that the equivalence of \( \infty \)-categories \( \mathcal{D}(\mathcal{A}) \simeq \text{Mod}_R \) provided by Remark 7.1.1.16 can be promoted to an equivalence of symmetric monoidal \( \infty \)-categories. To formulate this result more precisely, we need to define a suitable symmetric monoidal structure on \( \mathcal{D}(\mathcal{A}) \). Roughly speaking, it is given by the tensor product of chain complexes over \( R \). To analyze this tensor product more explicitly, it is convenient to introduce an appropriate model structure on \( \text{Ch}(\mathcal{A}) \).

Proposition 7.1.2.8. Let \( R \) be an associative ring and let \( \mathcal{A} \) be the abelian category of (discrete) right \( R \)-modules. Then the category \( \text{Ch}(\mathcal{A}) \) admits a left proper combinatorial model structure, which can be described as follows:

1. A map of chain complexes \( f : M_* \to N_* \) is a weak equivalence if it is a quasi-isomorphism: that is, if it induces an isomorphism on homology.
2. A map of chain complexes \( f : M_* \to N_* \) is a fibration if each of the maps \( M_i \to N_i \) is surjective.
3. A map of chain complexes \( f : M_* \to N_* \) is a cofibration if and only if it has the left lifting property with respect to every map \( g \) which is simultaneously a fibration and a weak equivalence.

Proof. For every integer \( n \), we let \( E(n)_* \) denote the chain complex

\[
\cdots \to 0 \to R \xrightarrow{id} R \to 0 \to \cdots
\]

which is nontrivial only in degrees \( n \) and \( n - 1 \), and we let \( \partial E(n)_* \) denote the subcomplex consisting of the module \( R \) concentrated in degree \( n - 1 \). Let \( C_0 \) be the collection of all monomorphisms of chain complexes...
7.1. STRUCTURED RING SPECTRA

\{\partial E(n)_* \hookrightarrow E(n)_*\}_{n \in \mathbb{Z}}. Let C be the smallest weakly saturated collection of morphisms containing C_0. We first show that there is a model structure on \text{Ch}(A) whose class of cofibrations is given by C and whose weak equivalences are quasi-isomorphisms. For this, it suffices to verify the hypotheses of Proposition T.A.2.6.13.

Note that every morphism in C is a cofibration with respect to the model structure of Proposition 1.3.5.3. It follows from Proposition 1.3.5.3 that the class of weak equivalences in \text{Ch}(A) is perfect and is stable under pushouts by morphisms in C. It therefore suffices to show that if \(f : M_* \rightarrow N_*\) is a morphism which has the right lifting property with respect to every morphism in C_0, then f is a quasi-isomorphism. Unwinding the definitions, our assumption guarantees that if \(x \in N_i\) and \(y \in M_{i+1}\) satisfy \(f(y) = dx\), then there exists an element \(\pi \in M_i\) with \(d\pi = y\) and \(f(\pi) = x\). Taking \(x\) to be an arbitrary cycle and \(y = 0\), we deduce that \(f\) induces a surjection \(H_1(M) \rightarrow H_1(N)\). To prove injectivity, choose a homology class \(\eta \in H_1(M)\) represented by \(y \in M_i\), and suppose that the image of \(\eta\) in \(H_1(N)\) vanishes. Then \(f(y) = dx\) for some \(x \in M_{i+1}\), and our hypothesis guarantees the existence of an element \(\pi \in M_{i+1}\) with \(d\pi = 0\), so that \(\eta = 0\) as desired.

To complete the proof, it suffices to show that the model structure we have constructed satisfies the requirements of Proposition 7.1.2.8: that is, we must show that a map \(f : M_* \rightarrow N_*\) is a fibration if and only if it is degreewise surjective. Assume first that \(f\) is a fibration. We wish to show that for every integer \(n\), \(f\) has the right lifting property with respect to the inclusion \(g : 0 \hookrightarrow E(n)_*\). The map \(g\) is clearly a quasi-isomorphism. Moreover, \(g\) can be obtained as a composition of maps

\[0 \overset{\delta'}{\rightarrow} \partial E(n)_* \overset{\delta''}{\rightarrow} E(n)_*\]

where \(g''\) belongs to \(C_0\) and \(g'\) is a pushout of the morphism \(\partial E(n-1)_* \rightarrow E(n-1)_*\), belonging to \(C_0\). It follows that \(g\) is a trivial cofibration, so that \(f\) has the right lifting property with respect to \(g\) by virtue of our assumption that \(f\) is a fibration.

Now suppose that \(f : M_* \rightarrow N_*\) is degreewise surjective; we wish to show that \(f\) is a fibration. Let \(g : P_* \rightarrow Q_*\) be a trivial cofibration in \text{Ch}(A). For every pair of chain complexes of right \(R\)-modules \(X_*\) and \(Y_*\), let \(\text{Map}(X, Y)_*\) be the chain complex of abelian groups given by Definition 1.3.2.1. We wish to show that the map

\[\phi : \text{Map}(Q_*, M)_* \rightarrow \text{Map}(P_*, M)_* \times_{\text{Map}(P_*, N)_*} \text{Map}(Q_*, N)_*\]

is surjective on 0-cycles. Since \(g\) is a trivial cofibration, each of the maps \(P_n \rightarrow Q_n\) is a split monomorphism, and each quotient \(F_n = Q_n/P_n\) is a projective right \(R\)-module. We therefore obtain a diagram of exact sequences (of chain complexes of abelian groups)

\[0 \longrightarrow \text{Map}(F_*, M)_* \longrightarrow \text{Map}(Q_*, M)_* \longrightarrow \text{Map}(P_*, M)_* \longrightarrow 0\]

\[0 \longrightarrow \text{Map}(F_*, N)_* \longrightarrow \text{Map}(Q_*, N)_* \longrightarrow \text{Map}(P_*, N)_* \longrightarrow 0\]

Since \(F_*\) is degreewise projective and \(f\) is degreewise surjective, the map \(\theta\) is an epimorphism. It follows from a diagram chase that the map \(\phi\) degreewise surjective, and that \(\ker(\phi) \simeq \ker(\theta)\). Let \(K_* = \ker(\phi)\), so that \(K_* \simeq \text{Map}(F_*, \ker(f))\). Let \(x\) be a 0-cycle in \(\text{Map}(P_*, M)_* \times_{\text{Map}(P_*, N)_*} \text{Map}(Q_*, N)_*\), and write \(x = \phi(\bar{x})\) for \(\bar{x} \in \text{Map}(Q_*, M)_0\). Then \(d\bar{x}\) is a (−1)-cycle of \(K\). If we can write \(d\bar{x} = dy\) for some \(y \in K_0\), then \(\bar{x} - y\) is a 0-cycle of \(\text{Map}(Q_*, M)_*\) lifting \(x\). It will therefore suffice to show that the chain complex \(K_*\) is acyclic. For this, it suffices to show that the chain complex \(F_*\) has a contracting homotopy.

We will prove the following more general assertion: for every cofibrant object \(Z_* \in \text{Ch}(A)\) and every map of chain complexes \(u : Z_* \rightarrow F_*\), where exists a nullhomotopy for \(u\): that is, a collection of maps \(h : Z_m \rightarrow F_{m+1}\) satisfying \(dh + hd = u\). Taking \(u\) to be the identity map \(id_{F_*}\), we will obtain the desired result. Without loss of generality we may assume that \(Z_*\) is the colimit of a transfinite sequence of chain complexes

\[0 = Z(0)_* \rightarrow Z(1)_* \rightarrow Z(2)_* \rightarrow \cdots\]
where each of the maps $Z(\alpha)_* \to Z(\alpha+1)_*$ is the pushout of an inclusion $\partial E(n_\alpha)_* \hookrightarrow E(n_\alpha)_*$. We construct a compatible family of maps $h_\alpha : Z(\alpha)_m \to F_{m+1}$ satisfying $dh_\alpha + h_\alpha d = u[Z(\alpha)_m]$ using induction on $\alpha$. When $\alpha$ is a limit ordinal (including the case $\alpha = 0$), there is nothing to prove. Let us therefore assume that $h_\alpha$ has been constructed, and explain how to define $h_{\alpha+1}$. By assumption, the chain complex $Z(\alpha + 1)_*$ is freely generated by $Z(\alpha)_*$ together with an additional element $x$ in degree $n_\alpha$, satisfying $dx = y \in Z(\alpha)_{n_\alpha - 1}$. The element $u(x) - h_\alpha(y) \in F_{n_\alpha}$ satisfies

$$d(u(x) - h_\alpha(y)) = u(dx) - dh_\alpha(y) - h_\alpha(dy) = u(y) - u(y) = 0,$$

so that $u(x) - h_\alpha(y)$ is a cycle. Since $g : P_* \to Q_*$ is a trivial cofibration, the chain complex $F_*$ is acyclic. We may therefore find an element $z \in F_{n_{\alpha+1}}$ with $dz = u(x) - h_\alpha(y)$. We now complete the construction by defining $h_{\alpha+1}$ so that $h_{\alpha+1}(x) = z$ and $h_{\alpha+1}|Z(\alpha)_* = h_\alpha$.

**Remark 7.1.2.9.** Let $R$ be an associative ring and $\mathcal{A}$ the abelian category of (discrete) $R$-modules. We will refer to the model structure on $\text{Ch}(\mathcal{A})$ described in Proposition 7.1.2.8 as the projective model structure on the category $\text{Ch}(\mathcal{A})$. It generally does not agree with the model structure of Proposition 1.3.5.3. However, these model structures have the same weak equivalences. It follows that the underlying $\infty$-category of $\text{Ch}(\mathcal{A})$ does not depend on which model structure we consider (it is the $\infty$-category obtained from $\text{Ch}(\mathcal{A})$ by formally inverting all weak equivalences). We will denote this $\infty$-category by $\mathcal{D}(\mathcal{A})$ in what follows.

**Remark 7.1.2.10.** Let $R$ be a field (not necessarily commutative). Then for every monomorphism $M \to N$ of right $R$-modules, the inclusion of the chain complex

$$\cdots \to 0 \to M \to N \to 0 \to \cdots$$

into

$$\cdots \to 0 \to N \xrightarrow{id} N \to 0 \to \cdots$$

is a pushout of coproducts of generating cofibrations appearing in Proposition 7.1.2.8. It follows that the model structures of Propositions 1.3.5.3 and 7.1.2.8 coincide. In particular, every object of $\text{Ch}(\mathcal{A})$ is cofibrant with respect to the projective model structure.

**Proposition 7.1.2.11.** Let $R$ be a commutative ring, let $\mathcal{A}$ denote the abelian category of (discrete) $R$-modules, and regard $\text{Ch}(\mathcal{A})$ as a symmetric monoidal category via the tensor product of chain complexes (see Remark 1.2.3.21). Then $\text{Ch}(\mathcal{A})$ is a symmetric monoidal model category, with respect to the projective model structure of Proposition 7.1.2.8.

**Proof.** It is easy to see that the unit object of $\text{Ch}(\mathcal{A})$ (given by the module $R$, considered as a chain complex concentrated in degree zero) is cofibrant. Suppose we are given cofibrations $f : M_* \to M'_*$ and $g : N_* \to N'_*$; we must show that the induced map

$$f \wedge g : (M_* \otimes N'_*) \coprod_{M_* \otimes N_*} (M'_* \otimes N_*) \to M'_* \otimes N'_*$$

is a cofibration, which is trivial if either $f$ or $g$ is trivial. We first show that $f \wedge g$ is a cofibration. Without loss of generality, we may assume that both $f$ and $g$ are generating cofibrations, having the form

$$\partial E(m)_* \to E(m)_* \quad \partial E(n)_* \to E(n)_*$$

for some integers $m$ and $n$ (for an explanation of this notation, see the proof of Proposition 7.1.2.8). Unwinding the definitions, we see that $f \wedge g$ is a pushout of the generating cofibration $\partial E(m+n)_* \to E(m+n)_*$, and therefore a cofibration.

Now suppose that $f$ is a trivial cofibration; we wish to show that $f \wedge g$ is a trivial cofibration. If we regard $f$ as fixed, then the collection of morphisms $g$ for which $f \wedge g$ is a trivial cofibration is weakly saturated. We may therefore assume that $g$ is a generating trivial cofibration of the form $\partial E(n)_* \to E(n)_*$. In this case, the map $f \wedge g$ is an injection whose cokernel is isomorphic (after a shift) to the cokernel of $f$. Since $f$ is a quasi-isomorphism which is degreewise injective, the chain complex $\text{coker}(f)$ is acyclic, so that $f \wedge g$ is also a quasi-isomorphism. □
Remark 7.1.2.12. Combining Proposition 7.1.2.11 with Example 4.1.3.6, we conclude that if $A$ is the abelian category of modules over a commutative ring $R$, then the derived category $\mathcal{D}(A)$ inherits a symmetric monoidal structure. This symmetric monoidal structure is determined uniquely (up to equivalence) by the requirement that the functor $N(\text{Ch}(A)^o) \to \mathcal{D}(A)$ can be promoted to a symmetric monoidal functor; here $\text{Ch}(A)^o$ denotes the full subcategory of $\text{Ch}(A)$ spanned by those objects which are cofibrant with respect to the model structure of Proposition 7.1.2.8.

We are now ready to address the question raised at the beginning of this section.

Theorem 7.1.2.13. Let $R$ be a commutative ring, let $A$ denote the abelian category of $R$-modules, and regard $R$ as a discrete $\mathbb{E}_\infty$-ring. Then there is a canonical equivalence of symmetric monoidal $\infty$-categories $\text{Mod}_R \to \mathcal{D}(A)$; here we regard $\mathcal{D}(A)$ as a symmetric monoidal $\infty$-category as in Remark 7.1.2.12.

Proof. The $\infty$-category $\mathcal{D}(A)$ is presentable by Proposition 1.3.4.22, and the tensor product on $\mathcal{D}(A)$ preserves colimits separately in each variable since it is induced by a left Quillen bifunctor. The $\infty$-category $\mathcal{D}(A)$ is stable by Remark 7.1.2.9 and the results of §1.3.2. Let $R$ be the unit object of $\mathcal{D}(A)$. For any $M \in \mathcal{D}(A)$, we have canonical equivalences $\mathbb{H}_n(M) \simeq \text{Ext}^{-n}_{\mathcal{D}(A)}(R, M)$. It follows that $R$ is a compact generator for $\mathcal{D}(A)$, so that Proposition 7.1.2.7 yields a symmetric monoidal equivalence $\mathcal{D}(A) \simeq \text{Mod}_A$ for some $\mathbb{E}_\infty$-ring $A$. Here we can regard $A$ as the endomorphism algebra of $R \in \mathcal{D}(A)$, so that

$$\pi_n A \simeq \text{Ext}^{-n}_{\mathcal{D}(A)}(R, R) \simeq \begin{cases} R & \text{if } n = 0 \\ 0 & \text{otherwise.} \end{cases}$$

In particular, we deduce that $A$ is a discrete $\mathbb{E}_\infty$-ring which can be identified with $R$, so that we have a symmetric monoidal equivalence $\mathcal{D}(A) \simeq \text{Mod}_R$. \qed

7.1.3 Change of Ring

Let $Ab$ denote the category of abelian groups and let $R \in \text{CAlg}(Ab)$ be a commutative ring. Suppose that $A$ is an $R$-algebra: that is, an associative ring equipped with a map $\phi : R \to A$ whose image is contained in the center of $A$. Suppose that $M$ is an $A$-module. We may then regard $M$ as an $R$-module (via the homomorphism $\phi$). The action of $A$ on $M$ is determined by a map of abelian groups $\phi : A \otimes M \to M$. This map is $R$-bilinear: for every triple of elements $a \in A$, $x \in M$, and $\lambda \in R$, we have

$$\lambda(ax) = (\lambda a)x = (a\lambda)x = a(\lambda x).$$

It follows that the map $\phi$ factors through the relative tensor product $A \otimes_R M$. We can rephrase this statement more categorically as follows: the associative ring $A$ can be regarded as an associative algebra object of the category $\text{Mod}_R(\text{Ab})$ of $R$-modules, and $M$ can be regarded as a left $A$-module object of the category $\text{Mod}_R(\text{Ab})$.

We begin this section by generalizing this observation to the $\infty$-categorical setting. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category and let $R \in \text{CAlg}(\mathcal{C})$ be a commutative algebra object of $\mathcal{C}$. Under some mild assumptions, the $\infty$-category $\text{Mod}_R(\mathcal{C})$ of $R$-module objects of $\mathcal{C}$ inherits the structure of a symmetric monoidal $\infty$-category. Moreover, the forgetful functor $\text{Mod}_R(\mathcal{C}) \to \mathcal{C}$ is lax symmetric monoidal. It follows that every algebra object $A \in \text{Alg}(\text{Mod}_R(\mathcal{C}))$ determines an algebra $A' \in \text{Alg}(\mathcal{C})$, and we have a forgetful functor $\text{LMod}_A(\text{Mod}_R(\mathcal{C})) \to \text{LMod}_{A'}(\mathcal{C})$. We will show that this forgetful functor is an equivalence of $\infty$-categories. In fact, we do not even need to assume that the tensor product on $\mathcal{C}$ is fully commutative.

Theorem 7.1.3.1. Let $\mathcal{C}$ be an $\mathbb{E}_2$-monoidal $\infty$-category. Assume that $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product on $\mathcal{C}$ preserves geometric realizations separately in each variable. Let $R \in \text{Alg}_{/\mathbb{E}_2}(\mathcal{C}) \simeq \text{Alg}_{/\mathbb{E}_1}(\text{Alg}_{/\mathbb{E}_2}(\mathcal{C}))$, so that the $\infty$-category $\text{LMod}_R(\mathcal{C})$ inherits an $\mathbb{E}_1$-monoidal structure. For every algebra object $A \in \text{Alg}_{/\mathbb{E}_1}(\text{LMod}_R(\mathcal{C}))$ having image $A' \in \text{Alg}_{/\mathbb{E}_2}(\mathcal{C})$, the forgetful functor $\theta : \text{LMod}_A(\text{LMod}_R(\mathcal{C})) \to \text{LMod}_{A'}(\mathcal{C})$ is an equivalence of $\infty$-categories.
Remark 7.1.3.2. With a bit more care, the conclusion of Theorem 7.1.3.1 remains valid for an arbitrary fibration of $\infty$-operads $p : \mathcal{C} \to \mathbb{E}_2^\otimes$: we do not need to assume that $p$ is a coCartesian fibration or that $p$ is compatible with $N(\Delta)^{op}$-indexed colimits. This more general statement can be reduced to the statement of Theorem 7.1.3.1 by first replacing $p$ by its $\mathbb{E}_2$-monoidal envelope (see §2.2.4) and then using Proposition 4.8.1.10.

Proof. In what follows, it will be convenient to think of the $\mathbb{E}_2$-monoidal structure on $\mathcal{C}$ as giving determining two tensor product operations $\otimes, \boxtimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$, which are coherently associative and commute with one another. The operations $\otimes$ and $\boxtimes$ can be identified with one another by the Eckmann-Hilton argument (see Example 5.1.2.4), but the argument will be clearer if we do not exploit this.

We have a diagram of forgetful functors

$$
\text{LMod}_A(\text{LMod}_R(\mathcal{C})) \xrightarrow{\theta} \text{LMod}_{A'}(\mathcal{C})
$$

$$
\xymatrix{ & \mathcal{C} \ar[ld]_{G'} \ar[rd]^{G} & \\
\text{LMod}_A(\text{LMod}_R(\mathcal{C})) & & \text{LMod}_{A'}(\mathcal{C})}
$$

To show that $\theta$ is an equivalence of $\infty$-categories, it will suffice to show that this diagram satisfies the hypotheses of Corollary 4.7.4.16. Using Corollaries 4.2.3.2 and 4.2.3.5, we deduce that $G$ and $G'$ are conservative and preserve geometric realizations of simplicial objects. Corollary 4.2.4.8 implies that $G'$ admits a left adjoint $F'$, given informally by

$$
\text{LMod}_A(\text{LMod}_R(\mathcal{C})) \xrightarrow{\theta_1} \text{LMod}_{A'}(\mathcal{C}) \xrightarrow{\theta_2} \mathcal{C}.
$$

Using Corollary 4.2.4.8 again, we deduce that these functors admit left adjoints $F_1$ and $F_2$. The functor $F_2$ is given by $M \mapsto R \boxtimes_R (A \otimes N)$. It follows that $G$ admits a left adjoint $F = F_1 \circ F_2$. To complete the proof, it will suffice to show that for each $M \in \mathcal{C}$, the canonical map $F'(M) \to \theta F(M)$ is an equivalence in $\text{LMod}_{A'}(\mathcal{C})$. Unwinding the definitions, we must show that the canonical map

$$
\alpha : A \otimes M \to R \boxtimes_R (A \otimes (R \boxtimes_R N))
$$

is an equivalence in $\mathcal{C}$. We note that $\alpha$ factors as a composition of equivalences

$$
A \otimes M \simeq R \boxtimes_R (A \otimes M) \simeq R \boxtimes_R (A \otimes (1 \boxtimes M)) \simeq R \boxtimes_R (A \otimes (R \boxtimes M)).
$$

The equivalences in Theorem 7.1.3.1 are compatible with the formation of relative tensor products:

Proposition 7.1.3.3. Let $\mathcal{C}$ be an $\mathbb{E}_2$-monoidal $\infty$-category. Assume that $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product on $\mathcal{C}$ preserves geometric realizations separately in each variable. Let $R \in \text{Alg}_{/\mathbb{E}_1}(\mathcal{C}) \simeq \text{Alg}_{/\mathbb{E}_1}(\text{LMod}_R(\mathcal{C}))$, so that the $\infty$-category $\text{LMod}_R(\mathcal{C})$ inherits an $\mathbb{E}_1$-monoidal structure. Let $\theta : \text{LMod}_R(\mathcal{C}) \to \mathcal{C}$ denote the forgetful functor. Suppose we are given an algebra object $A \in \text{Alg}_{/\mathbb{E}_1}(\text{LMod}_R(\mathcal{C}))$, and let $A'$ be the image of $A$ in $\text{Alg}_{/\mathbb{E}_1}(\mathcal{C})$, so that $\theta$ induces forgetful functors $\theta_L : \text{LMod}_A(\text{LMod}_R(\mathcal{C})) \to \text{LMod}_A(\mathcal{C})$ and $\theta_R : \text{RMod}_A(\text{LMod}_R(\mathcal{C})) \to \text{RMod}_A(\mathcal{C})$ (which are equivalences of $\infty$-categories by Proposition 7.1.3.1). For every pair of objects $M \in \text{RMod}_A(\text{LMod}_R(\mathcal{C}))$, $N \in \text{LMod}_A(\text{LMod}_R(\mathcal{C}))$, the canonical map

$$
\phi_{M,N} : \theta_R(M) \otimes_{A'} \theta_L(N) \to \theta(M \otimes_A N)
$$

is an equivalence in $\mathcal{C}$. 

\qed
Definition 7.1.3.5 continues to make sense in the special case Variant 7.1.3.8.

Combine Theorem 7.1.3.1, Proposition 7.1.3.3, and Theorem 4.4.1.28.

Proof. Let us regard $N \in \text{LMod}_A(\text{LMod}_R(\mathcal{C}))$ as fixed, and let $X \subseteq \text{RMod}_A(\text{LMod}_R(\mathcal{C}))$ be the full sub-category spanned by those objects for which the map $\phi$ is an equivalence. Since the forgetful functor $\theta$ and the relative tensor product functors commute with geometric realization, we conclude that $X$ is stable under geometric realizations in $\text{RMod}_A(\text{LMod}_R(\mathcal{C}))$. Using Proposition 4.7.4.14, we are reduced to proving that $X$ contains the essential image of the functor $F$ appearing in the proof of Theorem 7.1.3.1. Unwinding the definitions, we must show that if $M_0 \in \mathcal{C}$, then the canonical map

$$(M_0 \otimes A') \otimes_A \theta_L(N) \rightarrow \theta((M_0 \otimes A) \otimes_A N)$$

is an equivalence. This is clear, since both sides can be identified with the absolute tensor product $M_0 \otimes N$. 

\[\square\]

Corollary 7.1.3.4. Let $k \geq 1$ be an integer and let $\mathcal{C}$ be an $\mathbb{E}_{k+1}$-monoidal $\infty$-category. Assume that $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product on $\mathcal{C}$ preserves geometric realizations of simplicial objects separately in each variable. Let $R$ be an $\mathbb{E}_{k+1}$-algebra in $\mathcal{C}$, let $A \in \text{Alg}_{/\mathbb{E}_k}(\text{LMod}_R(\mathcal{C}))$, and let $A'$ denote the image of $A$ in $\text{Alg}_{/\mathbb{E}_k}(\mathcal{C})$. Then the forgetful functor

$$\text{LMod}_A(\text{LMod}_R(\mathcal{C})) \rightarrow \text{LMod}_{A'}(\mathcal{C})$$

is an equivalence of $\mathbb{E}_{k-1}$-monoidal $\infty$-categories.

Proof. Combine Theorem 7.1.3.1, Proposition 7.1.3.3, and Theorem 4.4.1.28. 

We now specialize to the setting of structured ring spectra.

Definition 7.1.3.5. Let $k \geq 0$, and let $R \in \text{Alg}_{/\mathbb{E}_k}(\mathbb{E}_{k+1})$ be an $\mathbb{E}_{k+1}$-ring. We let $\text{LMod}_R$ denote the $\infty$-category $\text{LMod}_R(\text{Sp})$ of left $R$-module spectra, which we regard as an $\mathbb{E}_{k+1}$-monoidal $\infty$-category. We let $\text{Alg}^{(k)}_R$ denote the $\infty$-category $\text{Alg}_{/\mathbb{E}_k}(\text{LMod}_R)$. We will refer to $\text{Alg}^{(k)}_R$ as the $\infty$-category of $\mathbb{E}_k$-algebras over $R$.

Example 7.1.3.6. Let $R = S$ be the sphere spectrum, regarded as a trivial $\mathbb{E}_{k+1}$-algebra object of $\text{Sp}$. Then the forgetful functor $\text{LMod}_R \rightarrow \text{Sp}$ is an equivalence of $\mathbb{E}_k$-monoidal $\infty$-categories. It follows that the forgetful functor $\text{Alg}^{(k)}_R \rightarrow \text{Alg}^{(k)}_R$ is an equivalence: that is, an $\mathbb{E}_k$-algebra over the sphere spectrum is just an $\mathbb{E}_k$-ring, in the sense of Definition 7.1.0.1.

Remark 7.1.3.7. Let $0 \leq k$, let $R$ be an $\mathbb{E}_{k+1}$-ring, and let $A$ be an $\mathbb{E}_k$-algebra over $R$. We will generally abuse notation by identifying $A$ with its image under the forgetful functor $\text{Alg}^{(k)}_R \rightarrow \text{Alg}^{(k)}_R$. Theorem 7.1.3.1 gives an equivalence of $\infty$-categories

$$\text{LMod}_A(\text{LMod}_R(\text{Sp})) \simeq \text{LMod}_A(\text{Sp}),$$

which is $\mathbb{E}_{k-1}$-monoidal if $k > 0$ (by Corollary 7.1.3.4). Consequently, we may speak unambiguously about (left) $A$-module spectra and their relative tensor product over $A$, without making reference to the underlying $\mathbb{E}_{k+1}$-ring $R$.

Variant 7.1.3.8. Definition 7.1.3.5 continues to make sense in the special case $k = \infty$: if $R$ is an $\mathbb{E}_\infty$-ring, then the $\infty$-category $\text{Mod}_R(\text{Sp}) \simeq \text{LMod}_R(\text{Sp})$ inherits a symmetric monoidal structure, so that the $\infty$-category $\text{CAlg}(\text{LMod}_R(\text{Sp}))$ is well-defined. We will denote this $\infty$-category by $\text{CAlg}_R$ and refer to its objects as $\mathbb{E}_\infty$-algebras over $R$. Using Theorem 5.1.4.10 and Proposition 3.4.1.4, we obtain a canonical equivalence of $\infty$-categories $\text{CAlg}_R \simeq \text{CAlg}_{R/}$: that is, we can identify an $\mathbb{E}_\infty$-algebra over $R$ with an $\mathbb{E}_\infty$-ring $A$ together with a map $R \rightarrow A$.

Warning 7.1.3.9. Let $k < \infty$ and let $R$ be an $\mathbb{E}_{k+1}$-ring. We can identify the unit object of $\text{LMod}_R$ with $R$ itself, so there is an evident forgetful functor

$$\text{Alg}^{(k)}_R \simeq (\text{Alg}^{(k)}_R)_{R/} \rightarrow \text{Alg}^{(k)}_R.$$
Let \( 0 \leq k \leq \infty \) and let \( R \) be a connective \( \mathbb{E}_{k+1} \)-ring. We will say that an \( \mathbb{E}_k \)-algebra \( A \in \text{Alg}^{(k)}_{\mathbb{E}_R} \) is connective if its underlying spectrum is connective. We let \( \text{Alg}^{(k),\text{cn}}_{\mathbb{E}_R} \) denote the full subcategory of \( \text{Alg}^{(k)}_{\mathbb{E}_R} \) spanned by the connective \( \mathbb{E}_k \)-algebras over \( R \). Note that \( \text{Alg}^{(k),\text{cn}}_{\mathbb{E}_R} \) can be identified with the \( \infty \)-category of \( \mathbb{E}_k \)-algebra objects of the subcategory \( \text{LMod}^{\text{cn}}_R \subseteq \text{LMod}_R \). To study this notion, we need the following observation:

**Lemma 7.1.3.10.** Let \( 0 \leq k \leq \infty \) and let \( R \) be a connective \( \mathbb{E}_{k+1} \)-ring. Then the \( t \)-structure on \( \text{LMod}_R \) (see Proposition 7.1.1.13) is compatible with the \( \mathbb{E}_k \)-monoidal structure.

**Proof.** If \( k = 0 \), it suffices to show that the unit object of \( \text{LMod}_R \) is connective; this unit object is given by \( R \), so the result is immediate. If \( k \geq 1 \), we must also show that for \( M, N \in \text{LMod}^{\text{cn}}_R \), the tensor product \( M \otimes_R N \) also belongs to \( \text{LMod}^{\text{cn}}_R \). Since \( \text{LMod}^{\text{cn}}_R \) is generated by \( R \) under small colimits, we can assume that \( M = N = R \), in which case the result is obvious.

For any object \( A \in \text{Alg}^{(k)}_{\mathbb{E}_R} \), we can find a closest approximation to \( A \) which belongs to \( \text{Alg}^{(k),\text{cn}}_{\mathbb{E}_R} \).

**Definition 7.1.3.11.** Let \( R \) be a connective \( \mathbb{E}_{k+1} \)-ring for \( 0 \leq k \leq \infty \) and let \( A \in \text{Alg}^{(k)}_{\mathbb{E}_R} \). A connective cover of \( A \) is a morphism \( \phi : A' \to A \) of \( \mathbb{E}_k \)-algebras over \( R \) with the following properties:

1. The \( \mathbb{E}_k \)-algebra \( A' \) is connective.
2. For every connective object \( A'' \in \text{Alg}^{(k)}_{\mathbb{E}_R} \), composition with \( \phi \) induces a homotopy equivalence
   \[
   \text{Map}_{\text{Alg}^{(k)}_{\mathbb{E}_R}}(A'', A') \to \text{Map}_{\text{Alg}^{(k)}_{\mathbb{E}_R}}(A'', A).
   \]

**Remark 7.1.3.12.** In the situation of Definition 7.1.3.11, we will generally abuse terminology and simply refer to \( A' \) as a connective cover of \( A \), in the case where the map \( \phi \) is implicitly understood.

**Proposition 7.1.3.13.** Let \( 0 \leq k \leq \infty \), and let \( R \) be a connective \( \mathbb{E}_{k+1} \)-ring. Then:

1. Every \( \mathbb{E}_k \)-algebra \( A \in \text{Alg}^{(k)}_{\mathbb{E}_R} \) admits a connective cover.
2. An arbitrary map \( \phi : A' \to A \) of \( \mathbb{E}_k \)-algebras over \( R \) is a connective cover of \( A \) if and only if \( A' \) is connective and the induced map \( \pi_n A' \to \pi_n A \) is an isomorphism for \( n \geq 0 \).
3. The inclusion \( \text{Alg}^{(k),\text{cn}}_{\mathbb{E}_R} \subseteq \text{Alg}^{(k)}_{\mathbb{E}_R} \) admits a right adjoint \( G \), which carries each \( \mathbb{E}_k \)-algebra \( A \in \text{Alg}^{(k)}_{\mathbb{E}_R} \) to a connective cover \( A' \) of \( A \).

**Proof of Proposition 7.1.3.13.** Combine Proposition 2.2.1.1 with Lemma 7.1.3.10.

Recall that an object \( X \) of an \( \infty \)-category \( \mathcal{C} \) is said to be \( n \)-truncated if the mapping spaces \( \text{Map}_{\mathcal{C}}(Y, X) \) are \( n \)-truncated, for every \( Y \in \mathcal{C} \) (see §5.5.6). Let \( R \) be a connective \( \mathbb{E}_{k+1} \)-ring for \( 0 \leq k \leq \infty \). Corollary 3.2.3.5 implies that the \( \infty \)-categories \( \text{Alg}^{(k)}_{\mathbb{E}_R} \) and \( \text{Alg}^{(k),\text{cn}}_{\mathbb{E}_R} \) are presentable for \( 0 \leq k \leq \infty \), so we have a good theory of truncation functors.

**Proposition 7.1.3.14.** Let \( 0 \leq k \leq \infty \), let \( R \) be a connective \( \mathbb{E}_{k+1} \)-ring, and let \( A \in \text{Alg}^{(k)}_{\mathbb{E}_R} \). The following conditions are equivalent:

1. As an object of \( \text{Alg}^{(k),\text{cn}}_{\mathbb{E}_R} \), \( A \) is \( n \)-truncated.
2. As an object of \( \text{LMod}^{\text{cn}}_R \), \( A \) is \( n \)-truncated.
(3) As an object of $\text{Sp}^\cn$, $A$ is $n$-truncated.

(4) The space $\Omega^\infty(R)$ is $n$-truncated.

(5) For every $m > n$, the homotopy group $\pi_m R$ is trivial.

Proof. The equivalence (4) ⇔ (5) is easy (Remark T.5.5.6.4), and the equivalences (2) ⇔ (3) ⇔ (5) are explained in Warning 1.2.1.9. The implication (1) ⇒ (2) follows from Proposition T.5.5.6.16, since the forgetful functor $\text{Alg}^{(k),\cn}_R \to \text{LMod}^{\cn}_{\tau_k}$ preserves small limits (Corollary 3.2.2.5).

We now prove that (2) ⇒ (1). Assume that $A$ is $n$-truncated as a left $R$-module spectrum. Let $T : (\text{Alg}^{(k),\cn})^{op} \to S$ be the functor represented by $A$. Let $\mathcal{C} \subseteq \text{Alg}^{(k),\cn}_R$ be the full subcategory of $\text{Alg}^{(k),\cn}_R$ spanned by those objects $B$ such that $T(B)$ is $n$-truncated. We wish to prove that $\mathcal{C} = \text{Alg}^{(k),\cn}_R$. Since $T$ preserves limits (Proposition T.5.1.3.2) and the class of $n$-truncated spaces is stable under limits (Proposition T.5.5.6.5), we conclude that $\mathcal{C}$ is stable under small colimits in $\text{Alg}^{(k),\cn}_R$. Let $F$ be a left adjoint to the forgetful functor $\text{Alg}^{(k),\cn}_R \to \text{LMod}_R$. Proposition 4.7.4.14 implies that $\text{Alg}^{(k),\cn}_R$ is generated under colimits by the essential image of $F$. Consequently, it will suffice to show that $F(M) \in \mathcal{C}$ for every $M \in \text{LMod}_R$. Equivalently, we must show that the space $\text{Map}_{\text{Alg}^{(k),\cn}_R}(F(M), A) \simeq \text{Map}_{\text{LMod}_R}(M, A)$ is $n$-truncated, which follows from (2).

Let $R$ be a connective $\mathbb{E}_{k+1}$-ring, let $\tau_{\leq n} : \text{LMod}^{\cn}_R \to \text{LMod}^{\cn}_R$ be the truncation functor on connective left $R$-module spectra, and let $\tau_{\leq n} : \text{Alg}^{(k),\cn}_R \to \text{Alg}^{(k),\cn}_R$ be the truncation functor on connective $\mathbb{E}_k$-algebras over $R$. Since the forgetful functor $\theta : \text{Alg}^{(k),\cn}_R \to \text{LMod}^{\cn}_R$ preserves $n$-truncated objects, there is a canonical natural transformation $\alpha : \tau_{\leq n} \circ \theta \to \theta \circ \tau_{\leq n}$. Our next goal is to show that $\alpha$ is an equivalence.

**Proposition 7.1.3.15.** Let $0 \leq k \leq \infty$, let $R$ be a connective $\mathbb{E}_{k+1}$-ring, and let $n \geq 0$ be an integer. Then:

1. The localization functor $\tau_{\leq n} : \text{LMod}^{\cn}_R \to \text{LMod}^{\cn}_R$ is compatible with the $\mathbb{E}_k$-monoidal structure on $\text{LMod}^{\cn}_R$, in the sense of Definition 2.2.1.6.

2. The $\mathbb{E}_k$-monoidal structure on $\text{LMod}^{\cn}_R$ induces an $\mathbb{E}_k$-monoidal structure on the $\infty$-category

   $$\text{LMod}^{\cn}_R \cap (\text{LMod}_R)_{\leq n}$$

   and an identification

   $$\text{Alg}_{/\mathbb{E}_k}(\text{LMod}^{\cn}_R \cap (\text{LMod}_R)_{\leq n}) \simeq \tau_{\leq n}^{(k)} \text{Alg}^{(k),\cn}_R.$$

3. For every connective $\mathbb{E}_k$-algebra $A$ over $R$, the map of left $R$-module spectra $\tau_{\leq n} A \to \tau_{\leq n}^{(k)} A$ described above is an equivalence.

**Proof.** Assertion (1) follows from Proposition 2.2.1.8 and Lemma 7.1.3.10. Assertions (2) and (3) follow from (1) together with Proposition 2.2.1.9. □

More informally, Proposition 7.1.3.15 asserts that if $A$ is connective $\mathbb{E}_k$-algebra over a connective $\mathbb{E}_{k+1}$-ring $R$, then for each $n \geq 0$ the truncation $\tau_{\leq n} A$ inherits the structure of an $\mathbb{E}_k$-algebra over $R$.

**Remark 7.1.3.16.** Let $k \geq 1$ and let $R$ be a connective $\mathbb{E}_{k+1}$-ring. The $\mathbb{E}_k$-monoidal structure on $\text{LMod}_R$ induces an $\mathbb{E}_k$-monoidal structure on the subcategory $\text{LMod}^{\circ}_R$ of discrete objects of $\text{LMod}_R$, which is equivalent to the nerve of the ordinary category of discrete modules over $\pi_0 R$. This $\mathbb{E}_k$-monoidal structure is given by the usual tensor product of modules over the commutative ring $\pi_0 R$. This follows, for example, from Theorem 7.1.2.13. We will discuss this point at greater length in §7.2.1.

**Definition 7.1.3.17.** Let $0 \leq k \leq \infty$ and let $R$ be a connective $\mathbb{E}_{k+1}$-ring. We say that an $\mathbb{E}_k$-algebra $R$ is discrete if it is connective and $0$-truncated. We let $\text{Alg}^{(k)}_{R, \text{disc}}$ denote the full subcategory of $\text{Alg}^{(k)}_R$ spanned by the discrete objects.
Since the mapping spaces in $\text{Alg}_{\mathbb{R}}^{(k)\text{disc}}$ are 0-truncated, it follows that $\text{Alg}_{\mathbb{R}}^{(k)\text{disc}}$ is equivalent to the nerve of an ordinary category. We next identify the relevant category.

**Proposition 7.1.3.18.** Let $1 \leq k \leq \infty$, and let $R$ be a connective $\mathbb{E}_{k+1}$-ring. If $k = 1$, then the construction $A \mapsto \pi_0 A$ induces an equivalence from $\text{Alg}_{\mathbb{R}}^{(k)}$ to the (nerve of the) ordinary category of discrete associative algebras over $\pi_0 R$. If $k \geq 2$, then the construction $A \mapsto \pi_0 A$ determines an equivalence from $\text{Alg}_{\mathbb{R}}^{(k)}$ to the (nerve of the) ordinary category of discrete commutative algebras over $\pi_0 R$.

**Proof.** Using Proposition 7.1.3.15, we can identify $\text{Alg}_{\mathbb{R}}^{(k)\text{disc}}$ with the $\infty$-category of $\mathbb{E}_k$-algebra objects of the heart $\text{LMod}^\otimes_R$. Combining this with Remark 7.1.3.16, we see that $\text{Alg}_{\mathbb{R}}^{(1)\text{disc}}$ can be identified with the nerve of the category of associative algebras over $\pi_0 R$. When $k \geq 2$, Remark 7.1.3.16 and Corollary 5.1.1.7 imply that $\text{Alg}_{\mathbb{E}_k}(\text{LMod}^\otimes_R)$ can be identified with the nerve of the ordinary category of commutative $\pi_0 R$-algebras.

Let $0 \leq k \leq \infty$ and let $R$ be a connective $\mathbb{E}_{k+1}$-ring. Since the t-structure on $\text{LMod}_R$ is left complete (Proposition 7.1.1.13), the map

$$
\text{LMod}_R^{cn} \to \lim_{\leftarrow n} \text{LMod}_R^{cn} \cap (\text{LMod}_R)^{\leq n}
$$

is an equivalence of $\infty$-categories. The forgetful functor $\text{Alg}_{/\mathbb{E}_k}(\widehat{\text{Cat}}_\infty) \to \widehat{\text{Cat}}_\infty$ preserves small limits (Corollary 3.2.2.5), so that $\text{LMod}_R^{cn}$ is also a limit of the sequence $\{\text{LMod}_R^{cn} \cap (\text{LMod}_R)^{\leq n}\}$ in the $\infty$-category of $\mathbb{E}_k$-monoidal $\infty$-categories and therefore also in the $\infty$-category $\text{Op}_\infty$ of $\infty$-operads. This immediately implies the following:

**Proposition 7.1.3.19.** Let $0 \leq k \leq \infty$, and let $R$ be a connective $\mathbb{E}_{k+1}$-ring. Then the canonical map

$$
\text{Alg}_{\mathbb{R}}^{(k)\text{cn}} \to \lim_{\leftarrow n} (\tau_{\leq n} \text{Alg}_{\mathbb{R}}^{(k)\text{cn}})
$$

is an equivalence of $\infty$-categories. In other words, Postnikov towers are convergent in the $\infty$-category $\text{Alg}_{\mathbb{R}}^{(k)\text{cn}}$ of connective $\mathbb{E}_k$-algebras over $R$ (see Definition T.5.5.6.23).

### 7.1.4 Algebras over Commutative Rings

Let $R$ be a commutative ring, which we regard as a discrete $\mathbb{E}_\infty$-ring. Our goal in this section is to describe some explicit models for the $\infty$-category of $\mathbb{E}_1$-algebras over $R$ and (when $R$ contains the field $\mathbb{Q}$ of rational numbers) the $\infty$-category of $\mathbb{E}_\infty$-algebras over $R$. We begin by reviewing a bit of terminology.

**Definition 7.1.4.1.** Let $R$ be a commutative ring. A **differential graded algebra over $R$** is a graded associative algebra $A_\ast$ over $R$ equipped with a differential $d : A_\ast \to A_{\ast-1}$ satisfying the following conditions:

- The square of the differential $d$ is equal to zero.
- The map $d$ is a (graded) derivation. That is, we have the Leibniz rule $d(xy) = (dx)y + (-1)^m xdy$ for $x \in A_m, y \in A_n$.

If $A_\ast$ and $B_\ast$ are differential graded algebras over $R$, then a **morphism of differential graded algebras** $\phi : A_\ast \to B_\ast$ such that $\phi(dx) = d\phi(x)$. With this notion of morphism, the collection of differential graded algebras over $R$ forms a category, which we will denote by $\text{DGA}(R)$.

**Remark 7.1.4.2.** Let $R$ be a commutative ring and let $\mathcal{A}$ be the abelian category of (discrete) $R$-modules. Then we can identify differential graded algebras over $R$ with associative algebra objects in the category $\text{Ch}(\mathcal{A})$ of chain complexes of $R$-modules. This identification gives an equivalence of categories $\text{Alg}(\text{Ch}(\mathcal{A})) \simeq \text{DGA}(R)$. 

If we want to understand the structure of differential graded algebras over $R$, we should begin by studying the tensor product of chain complexes over $R$.

**Proposition 7.1.4.3.** Let $R$ be a commutative ring, let $A$ be the category of $R$-modules, and regard $\text{Ch}(A)$ as a symmetric monoidal model category with respect to the projective model structure of Proposition 7.1.2.8. Then $\text{Ch}(A)$ satisfies the monoid axiom (see Definition 4.1.4.1).

**Proof.** Let $U$ be the collection of all morphisms in $\text{Ch}(A)$ of the form $M_* \otimes N'_* \to M_* \otimes N_*$, where $N'_* \to N_*$ is a trivial cofibration. Let $\overline{U}$ be the weakly saturated class of morphisms generated by $U$. We wish to show that every morphism in $\overline{U}$ is a quasi-isomorphism. We will prove a stronger assertion: namely, every morphism in $U$ is a trivial cofibration with respect to the model structure described in Proposition 1.3.5.3. For this, it suffices to show that every morphism in $U$ is a trivial cofibration with respect to the model structure of Proposition 1.3.5.3.

Let $M_*$ be an arbitrary object of $\text{Ch}(A)$, and let $f : N'_* \to N_*$ be a trivial cofibration with respect to the projective model structure; we wish to show that the induced map $F : M_* \otimes N'_* \to M_* \otimes N_*$ is a trivial cofibration with respect to the model structure of Proposition 1.3.5.3. We have an exact sequence of chain complexes

$$0 \to N'_* \to N_* \to N''_* \to 0$$

where each of the maps

$$0 \to N'_* \to N_* \to N''_* \to 0$$

is split exact. It follows that the sequence of chain complexes

$$0 \to M_* \otimes N'_* \xrightarrow{F} M_* \otimes N_* \to M_* \otimes N''_* \to 0$$
